
3. The sprayer must be constructed in such a manner that it can be easily and quickly taken apart for cleaning and quickly replaced.
4. The noise should be reduced to a minimum.

During the writer's experience and tests with a large number of sprayers, he has found that the "Rusden-Eeles" sprayer (Fig. 33) conforms more nearly to these requirements than any other. The spray is very fine; in fact, with astatki the flame can be regulated so as to have the appearance and character of a gas flame. The steam consumption is low, and the construction allows it to

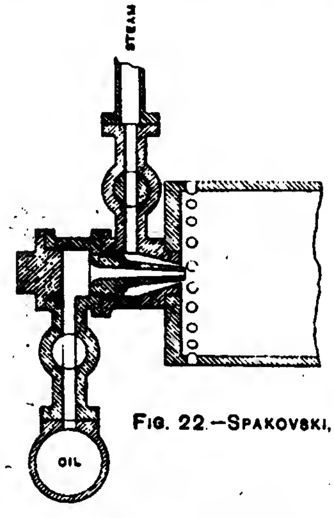

FIG. 22.—SPAKOVSKI, 1870.

be quickly and easily cleaned. In the latter sprayers the blow-through cock, shown in Fig. 33, is omitted, it being found easier and more effective to take the tube out and clean it than to blow the oil space through with the steam. Fig. 34 shows the arrangement of the complete installation as applied to a two-furnaced marine boiler.

In arranging an installation, the principal points are: (1) the superheating of the steam; (2) ample area in the fuel pipes, especially if heavy oil is used, and in the case of very heavy oils they may be required to be heated; (3) the supply tank should be placed in such a position as to ensure a constant and steady supply to the burner. Brickwork in the furnaces should be arranged in a manner so as to ensure the complete combustion of the fuel in the furnace, and to prevent the too rapid cooling of the furnace after the flame is extinguished.

In some cases, where the boiler is placed in a confined space, or there is not height enough to obtain a steady pressure on the burners from the supply tank, the oil may be pumped direct to the burners if a controlling valve is connected to the steam pipe of the pump; a valve of this character is illustrated in Fig. 35. This valve will regulate the speed of the pump automatically, and maintain a constant pressure in the oil supply pipes, no matter how many sprayers may be in use.

In relighting a furnace which has been extinguished for a short time lies the greatest danger of explosion of oil gas and the accompanying back flash from the furnace doors. Any small leakage or drip of oil finding its way into the heated furnace gasifies and forms an explosive mixture with the air, and if the lighting-up torch is introduced into a furnace under these conditions an explosion is sure to take place, and the person introducing the torch is very possibly burnt. Before lighting a furnace it should be well blown through with steam, and care taken to see that the steam jet is open first and the torch placed in the furnace before the oil valve is opened, in order that the spray may ignite as soon as it enters the furnace. If these precautions are taken, there is not the slightest danger of explosions, even if fuel with a low flash point is used.

The result obtained by several experimenters, that the average evaporation of liquid fuel is twice that of coal, has been confirmed by a long series of experiments conducted by the writer under the instructions of the Wallsend Slipway and Engineering Company (Limited), with various sprayers.

The boiler, which is of the ordinary marine type, evaporated with coal fuel from 7 to 8 lbs. of water from and at 212° F. for each pound of coal burnt, the uptake temperature being about 650° F.; with Russian astatki, the evaporation was from 13 to 18 lbs. from and at 212° F. per lb. of oil. The following are the average data from some experiment with a Rusden and Eeles sprayer, and a heat account from the same data :—

Kind of Liquid Fuel.	Russian Astatki.
Specific gravity	·9
Chemical analysis (approximate) :—	
Carbon	87 per cent.
Hydrogen	12 „
Oxygen	1 „
Temperature of stokehold	60° F.
„ escaping gases	450° F.
Weight of steam required to spray 1 lb. of oil ...	·3 lb.

Assuming that the air contained 23 per cent. of oxygen, and that the excess of air over that required for complete combustion passing into the furnace was 20 per cent., which would be about correct, because the slightest reduction of air caused smoke to issue from the chimney.

—		Heat Units.		Equivalent Evaporation from and at 212° F.
Total heat from combustion of 1 lb. of oil—				
Carbon ·87 × 14,500 ... ... =		12,615

Heat lost in radiant heat, &c.			1,687	1·7
Heat absorbed by water in boiler...			15,456	16

In addition to the firing of boilers, liquid fuel has been used for various other purposes. Mr. Urquhart, in his paper before the Institution of Mechanical Engineers, shows how he has successfully applied it to scrap welding furnaces. Fig. 36 shows its application to a smith's hearth. Fig. 37 shows it applied to a brass melting furnace. It will be observed the furnace has two flues leading from it, one carries off the products of combustion and the other the fumes given off from the molten metal; this forms a convenient method of recovering a valuable bye-product. A furnace, with an arrangement somewhat similar to Fig. 1 has been used for the melting of wrought iron for the production of Mitis casting, the temperature of the furnace being about 4,000° F. In conclusion, the writer expresses his indebtedness to the works of Gulishambaroff, Carew, Brayley Hodgetts, Col. Soliani, Urquhart, and many others, for a great deal of the matter contained in this paper.

DISCUSSION.

Mr. G. D. WEIR said he was sure they all felt deeply thankful to Mr. Wallis for his very interesting and able paper. It appeared to him to supply a long-felt want among engineers, some of whom had a very hazy notion as to what sort of a machine an oil burner was, or if perchance they had examined the construction of some oil burners that were illustrated in the plates that were attached to Mr. Wallis's paper, which, perhaps, few of them present ever thought were in existence. The second paragraph on the first page of the paper seemed to be one of the points which it would be well to thoroughly ventilate, and he should feel extremely pleased if any member or friend present who had practical experience in the running of ships using liquid fuel would give the result of such experiences. For himself he felt that anyone having read or listened to Mr. Wallis's paper would think that it was high time vessels crossed the Atlantic with their bunkers full of oil instead of coal, and only a slight grey-coloured gas rising from their funnels in place of the dense volumes of jet-black smoke which they so often saw, and the problem of the smoke nuisance solved for ever. But would this state of affairs ever come to pass? He hardly thought so, and they might almost take for granted that they never would so long as the relation between the price of coal and the

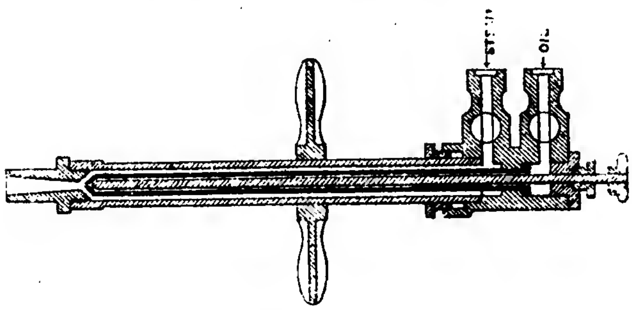

Fig. 23.—Lenz, 1872.

price of oil remained as at present, even if they could get the best burner that it was possible to have (a combination of the good points in the numerous burners illustrated rolled into one). The fact was, that so long as a shipowner could get more steam from 20*s*. worth of coal than he could get from 20*s*. worth of oil, then so long would coal hold the field against its rival. That such was the case to-day could be easily seen without recourse to patent burners or costly experiments. If they took the figures given in Table II, p. 401, of the paper they found that one pound of refuse oil would give out 19,832 British thermal units of heat, and one pound of Newcastle coal would give out 14,432 units if consumed or burnt with a proper admixture of oxygen, *i.e.*, the theoretical heat-producing power of equal quantities of oil and coal were in the ratio of 19,832 and 14,432, and if they bought a ton of oil, say, at market value, 34*s*., they could

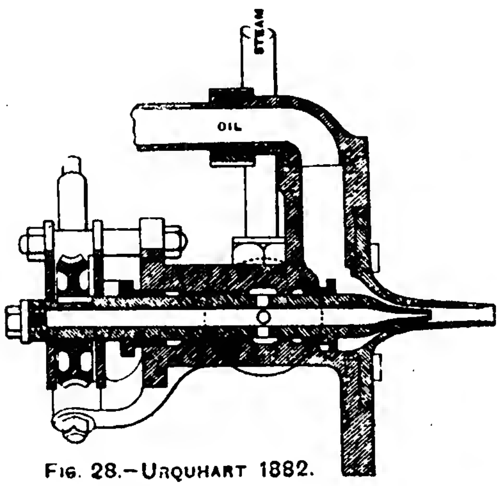

Fig. 28.—Urquhart 1882.

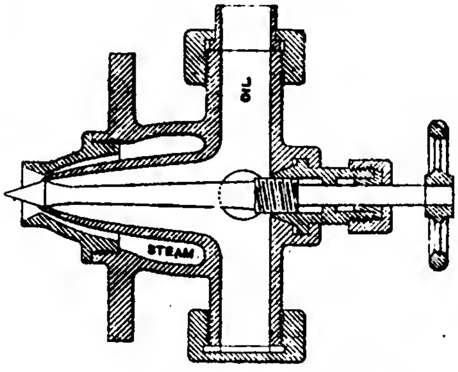

Fig. 29.—D'Allest, 1885.

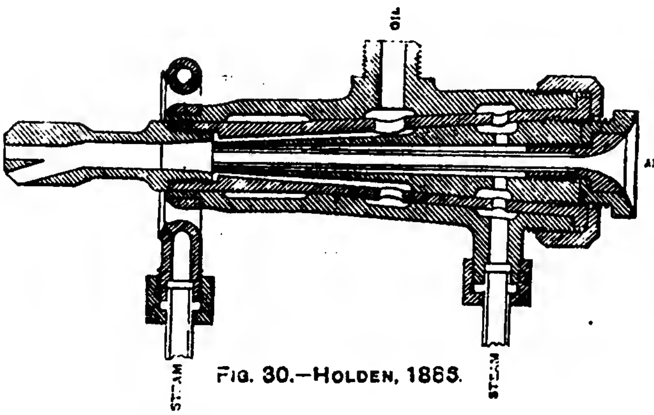

Fig. 30.—Holden, 1888.

buy four times the amount of coal, at, say, 8*s*. 6*d*. per ton, for the same money, and they got theoretically for the same money value 19,832 units of heat from the oil, and 57,728 units of heat from the coal, or if they turned to the end column of Table II, they could evaporate for the same cost twice as much water by using coal than if they had used oil, on condition that they bought the fuel in this country.

FIG. 31.—DUNDER.

In Table III were figures showing the amount of money which it would cost to run sister vessels, say with engines indicating 1,200 to 1,300 horse-power, one of the vessels fitted to burn oil as fuel, and the other to burn coal.

He had taken as an average consumption 20 tons of coal per day, and he had, for the sake of argument, taken the duration of the voyage from the United

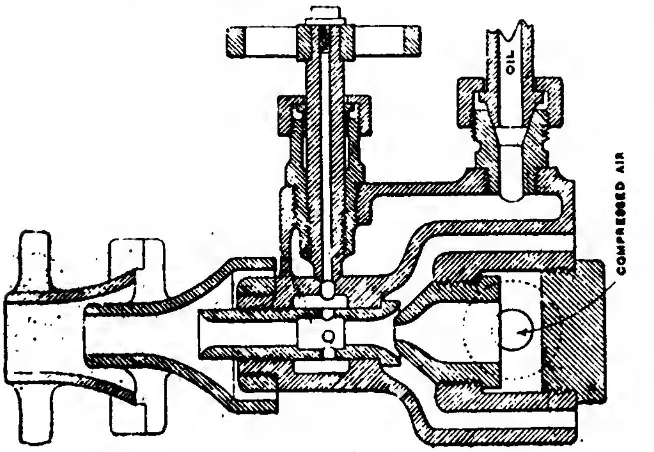

FIG. 32.—STEWART & FARMER. 1894.

Kingdom to be, say, 30 days or one month. He took Mr. Wallis's figures, viz., that it required twice the weight of coal compared with oil to give the same amount of steam, and as Mr. Wallis in his paper takes account of the cost of repairing fire-irons, &c., he (Mr. Weir) had debited the vessel burning coal with £10, which he thought was an ample allowance. From these figures they saw at a glance that the vessel using the coal was by far the less costly to run. He had not taken any account of the amount of fuel required for raising steam, nor of the amount of steam which would be used to drive the donkey for pumping the oil, so that the method of comparison was practically in favour of the oil, if anything. Perhaps, also, Mr. Wallis could say if the premium for insurance would be greatly increased in the vessel using oil, owing to the combustible contents of her bunkers. He should also be glad if Mr. Wallis could tell him if the wear and tear on the boilers was not greater when using oil than when using coal, owing to the intense heat concentrated in a practically small part of the furnace; and regarding this latter question he understood that there was a great deal of brickwork built into the furnaces, and perhaps Mr. Wallis would favour them with a sketch showing the method of arranging the brickwork, which he had found from his experience to give the best results. Of course, he did not wish it to be understood that it was not considerably cheaper to run vessels with liquid fuel when they were trading on, say, the Caspian or Black Seas, or even where vessels were trading regularly between such ports where the price of liquid fuel were less than the price of coal, or even if the price of oil was 60 per cent. greater than coal; then in such cases it would be found more economical to use oil, but unless the relative prices of the two fuels underwent a very considerable change, he did not think that they should ever see oil as fuel adopted by shipowners in this country. If, however, they turned from the stokehold of steam vessels and went to some of the large ironworks in the world he thought that at no very distant date they should find petroleum displacing coal. Some time ago, when looking into this question, he came across some very interesting statements, which perhaps would be of interest to them. At Woolwich, under ordinary circumstances, the armour-plate bending furnace was lighted some four or five hours before the plate was put in, the time occupied in heating the plate for bending depended upon its thickness, one hour per inch of thickness being allowed. Taking a 6-inch plate, they got from 10 to 11 hours from the time of starting till the plate was ready for bending. Let them now see what liquid fuel will do. The cold furnace was lighted, and after one hour it was found to be sufficiently heated, and a 6-inch armour plate, 7 feet 6 inches by 3 feet, was put in the furnace, and after one hour or an hour and a half it was ready for bending. Thus in two hours and a half they had the work of ten or eleven hours completely and satisfactorily performed. Nor did the advantages of this system stop there. The plate was remarkably free from scale, which could only be accounted for by the absence of the deterioratory influence of the products of combustion in the ordinary furnace. As proof of this it was said that thin plates, when heated by liquid fuel and bent double, showed no signs of cracking, as they usually did when heated in a coal furnace. This important feature was said to save 10s. per ton on the metal, which amount it would lose in deterioration under the modern mode of treatment. This method of supplying heat also offered another advantage, it could be applied to the whole or any portion of the plate. Thus, if a plate required to be bent at one end only, then the heat was directed to that part. Further, the rate at which the metal was heated could be regulated to a nicety by increasing or diminishing the number of jets in use.

Saving in iron by using gas ...	1,017	Saving by using oil gas as fuel	993

2 F 2

The data in Table IV were taken from the results of the operation of an iron furnace at St. Louis (Missouri), an interesting fact brought out being that the increased yield of iron made it profitable to employ petroleum as fuel. He believed, also, the time taken to complete the operation was less than one-half of that required by the ordinary method when using coal, and besides the economy manifested in these instances, the cleanliness and freedom from smoke and cinders were important considerations.

In conclusion, it must be conceded by everybody that, weight for weight, petroleum was a more valuable fuel than the best coal; but it could only be used in competition with coal when the value in £ s. d. of the manufactured article more than counterbalanced the difference in the price of the two kinds of fuel; and for steam raising in this country, he thought coal would always hold its own. Again he thanked Mr. Wallis for his interesting paper.

Mr. E. W. De Rusett said he would like to ask the author a few questions. Could the oil be carried in the ordinary double bottom of the vessel? Also, would there be any danger of the oil firing? Was it necessary to make any special provision to prevent such an accident? Could Mr. Wallis also tell them what the flashing point would be of this crude oil? Another question he would like to ask was, whether, in the comparisons of the work done by oil and coal, the amount of power absorbed in the evaporator in making up the steam used in spraying the oil was included? for a large amount of steam was necessarily used for this purpose, viz., ·3 lb. of steam to every 1 lb. of oil consumed.

other way. With the ordinary Wells light he had found it difficult to keep the burner clean. Perhaps Mr. Wallis might enlighten them on that matter. As one of the advantages of oil Mr. Wallis claimed that the boiler tubes were always free and clean, and therefore always in the best condition to transmit the heat from the gas to the water in the boiler. He (Mr. Seaman) had expected lamp black and spray being part of the difficulties of oil burning, and was rather pleased to find he was mistaken. With reference to the statement that there was a saving of tools, he did not know, but that would be balanced by the extra cost of repairs, for he took it there would be an extra expense and extra wages, as agreed upon for oil-carrying steamers, to be paid. The first speaker (Mr. Weir) gave them a very interesting table (No. III, p. 407). Could he give them any information as to the construction of this furnace? He would like to know something about that, especially with reference to the difference in waste shown with oil and with coal fuel.

Mr. Weir said if he could find time he would make a drawing of it for the next meeting.

Mr. T. Whitfield said this was the first meeting of the Institution he had attended, and he did not think he should have to speak on this subject. He might say that 12 years ago, when manager with Messrs. Wigham, Richardson, and Co., he fitted up three steamers for the Caspian Sea that were to be fueled by oil. They received the drawings in the usual way, and he must confess he was a little confused at first how to go about the work. The furnaces were lined

FIG. 33.—RUSDEN & EELES, 1896.

Mr. J. H. Heck said he had listened to Mr. Wallis's paper with a good deal of interest and attention. He thought the paper was a very good one, and an addition to the literature on the subject. He had not had very much experience in the use of liquid fuel, but had paid a good deal of attention to the transport question. While it was true, as Mr. Weir said, that oil could not at its present price compete with coal, there was no knowing what they might get in the future owing to the rapid development in new oil-fields. If the supply ever increased to a great extent, then he thought the amount of information given in the paper would be valuable. He believed the total production of petroleum per annum in the world was about 8,000,000 tons, and the oil refuse only about 2,000,000 tons, while the output of the world's coal was 400,000,000 tons. The quantity of oil produced, even if they used it all, would hardly be enough for the steamships at present in existence. Petroleum was too valuable as an illuminant to be used for fuel, and there were only some countries where it could be used for steamers. As to the use of liquid fuel, he could say there was no danger in using astatki, or even crude oil, if suitable arrangements were made. There was one thing he should mention. In the past he believed they had over-estimated the dangers that attended the transport of refined oil, and at the same time under-estimated the danger and attention required in carrying crude oil. He wished to express his thanks to Mr. Wallis for his very valuable paper.

Mr. C. J. Seaman said he had heard that the great difficulty with any oil burner was to keep it clean. Could Mr. Wallis tell them what was the best way to clean burners? He noticed between the lines of the paper a hint not to blow the steam through the burner, but rather to take it out and deal with it in some

with bricks. He could not quite remember what class of burner they were using, and he could not say whether the steam or the oil was at the top. At the first trial they had the usual commotion, with a certain amount of fear in the stokehold when the thing had to be lighted; he opened the tank valves and the steam valves, and away went the oil for 2½ hours; but they got nothing but huge volumes of black smoke. Everyone was surprised. They could have got steam up with coal in half the time. But as soon as the bricks got into a white heat, they saw through the peepholes the smoke diminish, and things went all right. He had the data of the evaporation trials at home. The name of the first steamer, he thought, was the "Flora"; she went out to the Black Sea, and he heard nothing more about her. They fitted up two after that, and he believed they were greater successes than the first. The tanks were fitted above the boiler. They had a large tank on the lower side of the boiler, a storage tank, with a small donkey engine fitted to keep up the supply. The difficulty they had was to keep the burners clean. That was overcome by a universal joint, as it were; and when one was supposed to be blocked up they took it off, cleaned it out, and put it back in its place.

Mr. H. Fownes confessed that he knew little about oil burning; but one of the advantages of an institution like this was that papers were read which raised an interest in questions that the majority of them possibly did not know much about. It led them to think about the subject and apply the information to their own business. He had nothing to do with burning oil in steamers; but he had in the matter ventilated by Mr. Weir—the saving of iron shown in Table IV. p. 407. The saving of iron, or any other material in course of manufacture, was an important matter. Still, it did not amount to a great deal from what appeared on the face of it, fur in the manufacture of iron there was 40 per cent. of waste from the scrap to the manufactured article: take that at 50*s.* the ton, it came to 20*s.* according to that table. He saw they saved 10 per cent. of that waste by using oil fuel, which would mean a saving of 2*s.*, so it would require a very considerable saving in other ways to make up for coal; and as Mr. Weir had kindly offered before the next meeting to let them have a sketch of this furnace, he was sure to those, such as himself, engaged in that particular business, it would prove of interest, and one they should certainly study with a view to economy in their manufacture.

Mr. J. M. Rennoldson thought they might in South Shields congratulate themselves upon having such an interesting subject treated as they had that night. He did not know that they, as north countrymen, would be likely to congratulate themselves upon the discovery of any system by which liquid fuel would supersede the burning of coal, although they were told from time to time by various prophets that the days of their coal supply were numbered. He did not think it would happen in this generation, nor yet in the next. So far as they were personally concerned they had not much to fear. The time might come when the production of oil would be very much greater than coal, and consequently cheaper than coal. When that day came there was no doubt that this balancing of accounts, these comparisons, would be very greatly altered. Meanwhile the position between their own and oil countries was reversed. A steamer, as she went further from the coal-fields and neared the oil wells, would find the cost of "bunkering" very much altered, and, indeed, in favour of the oil fuel, and he took it that was the reason why these steamers built in this country were made to burn liquid fuel, because they were for trading at ports nearer the oil wells than the coal-fields.

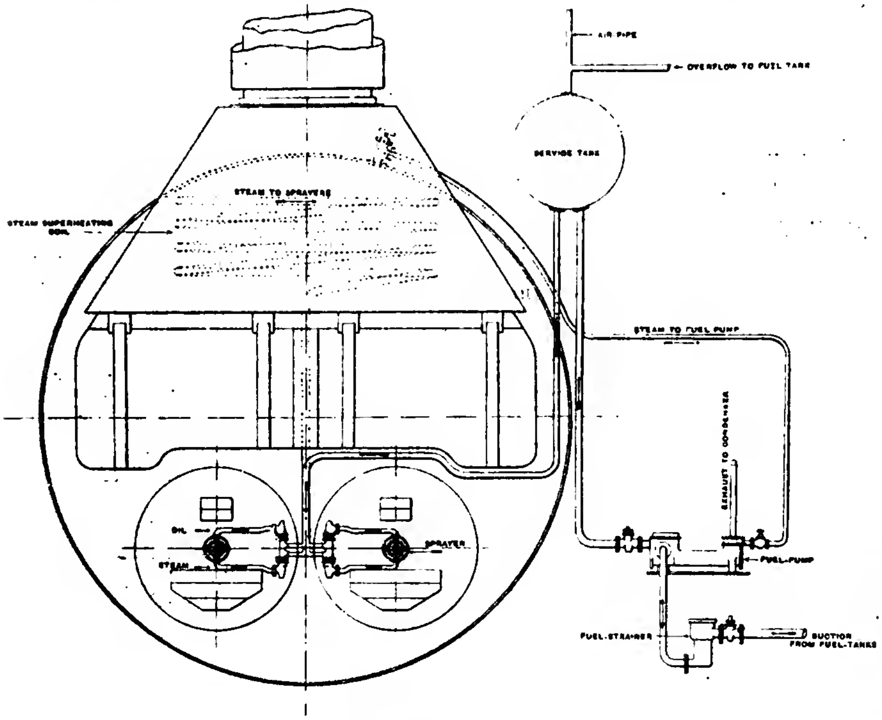

FIG. 34

One thing Mr. Weir omitted, and also Mr. Wallis, that was the cost of furnace bars, an item of very considerable importance in steamships, and certainly one that ought to be considered in favour of burning liquid fuel. There was one thing that would make this paper very much more interesting to members generally if to Fig. 34 was given a longitudinal section showing the brickwork. Several members had said they had had no experience in burning liquid fuel. That was a statement they could all endorse, for, with the exception of one or two firms on the river, no one in marine engineering had had much to do with the carrying out of liquid burning furnaces. Such an explanation, therefore, of the diagram would make the paper more interesting and intelligible generally. He hoped Mr. Wallis would be able to do something to clear up this point. He must thank Mr. Wallis for the very great trouble he had taken in the preparation of this paper; it was one of intense interest and certainly great satisfaction to them at that meeting.

Mr. F. W. Garbutt said there had been a question raised whether it was safe to use crude oil or astatki. He had been in Russia for the last two years, and had supplied most of the fuel oil to the Northern Caucasus Railway Company, who have over 250 locomotives at work. During the last year they had carried out a great many exhaustive experiments; also the Italian and German navies, and from the result of these trials they had come to the conclusion that it was not advisable to use oil fuel under a flashing point of 130° C. = 266° F.—and crude oil had a flashing point usually under 50° C. = 120° F.—and North Caucasian crudes of ·870 to ·878 specific gravity. Flashed below zero, mazoot or crude oil which had been exposed in open reservoirs long enough to allow the lighter and more volatile substances to evaporate was, however, mostly used on the Russian railways and Caspian Sea for fuel and lubricating purposes with very good results and it was found after an exposure of about three months to have a flashing point of 235° to 245° F. He quite agreed that oil fuel would never entirely take the place of coal in England, although the supply from Russia was almost unlimited, as the extra cost and transport charges debarred the use outside the limits where a regular and cheap supply could be obtained. He had been negotiating with the German Government, who had replied that, although they were highly satisfied with their experiments and the adoption of oil fuel, they could not leave themselves dependent upon a foreign country for the supply of fuel for their navy.

Mr. J. H. Heck said with reference to the use of crude oil as fuel, they could use it quite safely on a plan suggested by an English engineer residing in Italy. He (Mr. Heck) believed that gentleman was connected with some of the experiments made by the Italian Government. If his system were adopted it was impossible to have an explosion in the oil bunkers, and that was simply always to keep the oil bunkers completely full. The way to ensure this was that as the oil was used for consumption to allow water to go in, and so keep the oil bunkers completely full.

Mr. Garbutt said he referred only to the use of oil in locomotives, not for marine boilers.

The President said the subject was one which bristled with points of interest. To him it was especially interesting, as he had paid very great attention to everything concerning the carrying of petroleum and the burning of it, and there were a great many points which had not been touched upon, but which had an important bearing upon the subject. The comparison in Mr. Weir's table was taken with coal at 8*s.* 6*d.*, that was the price of coal at their own doors, and probably did not even include getting them into the bunkers. Even in London the price of coal would be very different from that; but going further afield, as Mr. Rennoldson remarked, the further from the coal supply and the nearer the oil supply, so would the advantage come in, and for war purposes, he believed, there was a great future in oil burning. One way in which it could always be utilised was for the smaller class of torpedo-boats. There was a difficulty in coaling them at sea, but in time of war there would be no difficulty in having a large tank-steamer anchored in a known latitude and longitude where these vessels could go and get a supply of oil fuel at any time without going to port for coals. Moreover, the transfer of oil from the supply steamer to the small vessels through pipes would be much more easily accomplished in a seaway than would the handling of coals. This was merely one incident in the matter.

At the next meeting of the Institution the Secretary read the following letter from Mr. L. Rusden, of Newcastle-on-Tyne:—

"I am very much indebted to the writer of this paper for the kindly reference to the oil burners that I am intimately connected with. Although oil burners of a different type were made long before the writer of this paper had anything to do with them, it was not until Mr. Alfred Suart gave the order to fit the s.s. "Baku Standard" for burning oil as fuel that serious attention was given to using oil in place of coal on English-owned steamers. The s.s. "Baku Standard" was the first steamer fitted for burning liquid fuel that crossed the Atlantic, and the result of the trial was anxiously awaited by many, as doubts were expressed about the use of this fuel as being unpractical. However, the use of liquid fuel in the s.s. "Baku Standard" was a marked success, and the owner (Mr. Alfred Suart) may be congratulated on the result; but, like many other things, owing to the exigencies of the trade, it had to be abandoned. If oil fuel could be supplied to meet the demands and could also be secured at a reasonable price, we should then begin another era in ocean steam navigation. The saving of oil fuel will be very considerable as compared with coal, more especially regarding labour and cleanliness, but I am afraid the day is far distant when oil will supersede coal, though on the Caspian Sea and district immediately surrounding it for some years have been using liquid fuel. The boiler for burning liquid fuel needs to be specially designed for economical results, although it can be used in an ordinary boiler. For instance, a boiler containing a certain number of square feet of heating surface requires to be less in diameter and of a greater length for using oil fuel than for coal, the furnaces and tubes being proportionably smaller. The brickwork in the furnace also needs careful attention. After the oil burner has been under way the brick arch built inside the furnace serves not only to break the force of the injected oil, but it serves in its heated state to assist the combustion, and to prevent too rapid cooling of the furnace when burners are put out. The heat being more uniform around the furnaces, the firebricks at the bottom cause a better circulation in the boiler. The writer of the paper has had considerable experience of the use of oil as fuel, he having carried out all the experiments with the oil burning for the firm he so ably represents."

Mr. J. R. Fothergill said that Mr. Wallis's paper treated upon a subject of very great interest. The consumption of liquid fuel instead of coal for general use in steamers had been frequently advocated, and no doubt was in certain districts, such for instance as the Caspian Sea, most advantageous, but there were considerations in its general application to steamers trading from this country which prevented its use. He apprehended there would be some difficulty in carrying petroleum in bulk. Mr. Wallis proposed utilising the present bunkers, but he was afraid it would be found a very difficult matter to make the bunkers absolutely tight.

Mr. R. Harkness: Not at all.

Mr. Fothergill said he deferred to the experience of Mr. Harkness, and was glad to hear such was the case. Possibly it might be more advantageous to use the ballast tanks in preference to the bunkers. There was, of course, no question as to the greater evaporative efficiency of petroleum as compared with coal, and that was readily seen by reference to Table 11, p. 401. From this table they might take it that in petroleum there was an average of 13 per cent. of hydrogen, whereas in coal 5 per cent. might be taken as the average, and it must also be remembered coal contained a very much larger percentage of oxygen. Hydrogen consumed to water-steam, evolves 62,000 units of heat, whereas carbon consumed to carbonic acid evolved only 14,500 units, and thus it was readily under-

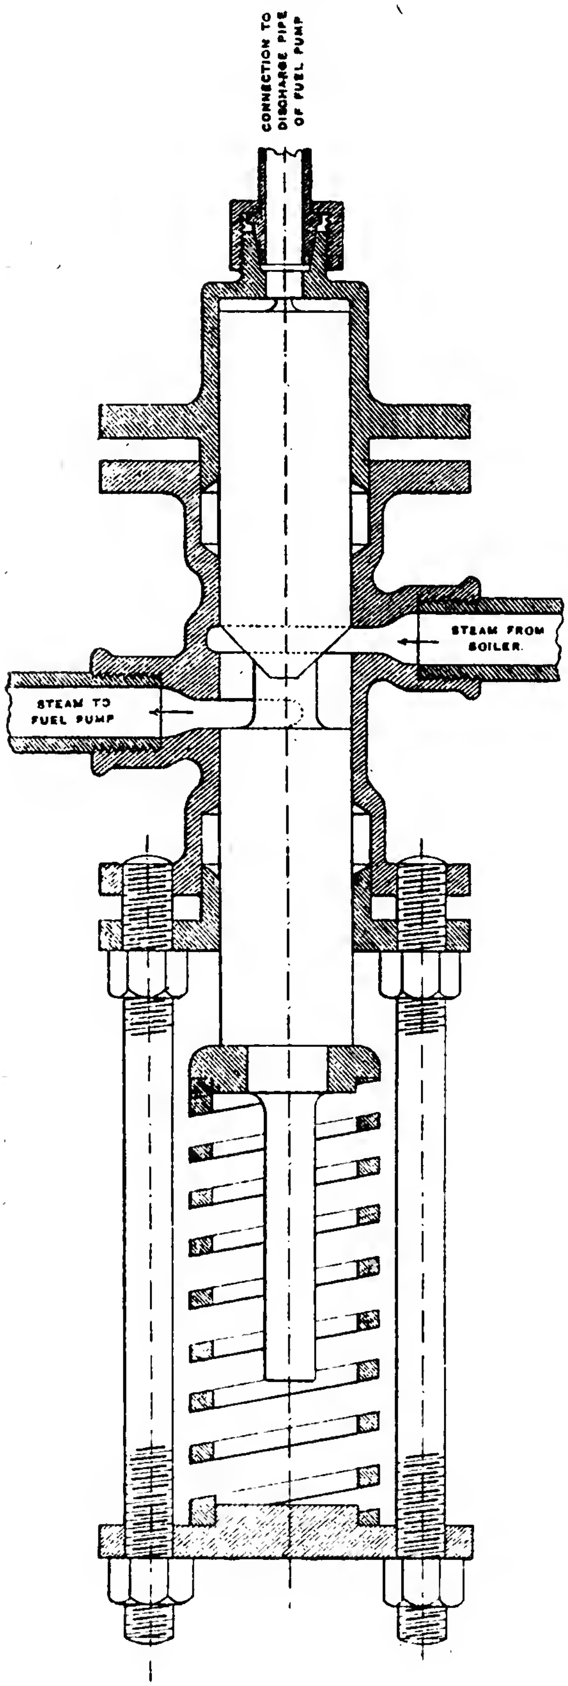

Fig. 35. Rusden & Eeles. Automatic Control Valve.

stood, from this consideration only, that petroleum offered in evaporative efficiency a considerable advantage over coal at least equal to 2 to 1. Then there were other advantages which Mr. Wallis had so lucidly described in his paper that it was quite unnecessary to repeat them. Mr. Wallis had classed various systems for burning liquid fuel under three heads. He (Mr. Fothergill) said, if they could readily vaporise or gasify petroleum oil, such vapour could be burnt to the best and highest evaporative efficiency, but they would be dealing with an article that was very dangerous, almost as explosive as gunpowder, and when dealing with it in large quantities, such as would be required for marine consumption, it was exceedingly danegrous and to be avoided. Experience

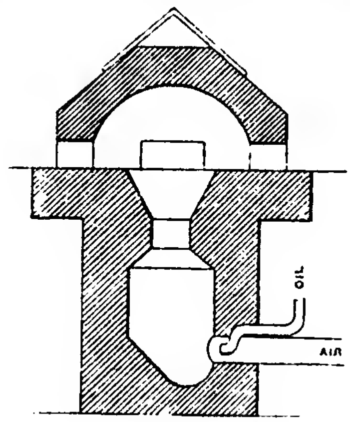

Fig. 36.—Oil Fuel Forge.

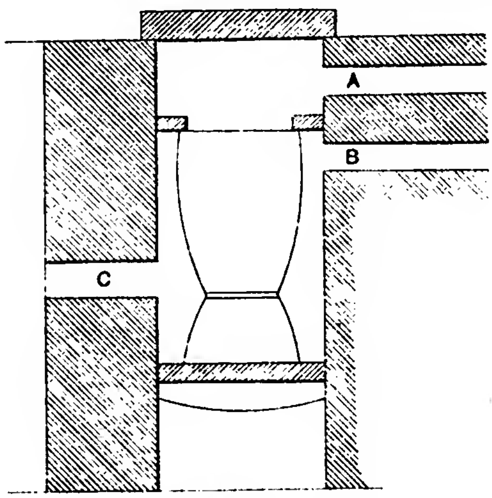
proved that spraying was the most practicable and applicable to marine boilers. Mr. Wallis also classed under three heads various methods of spraying. In deciding the class of sprayer, consideration must be given to the kind of oil to be used. Although for marine purposes the use of steam might be objected to, yet there was one great advantage in using high-pressure steam, and particularly when superheated, that compressed air did not offer. Steam under such conditions had the power of breaking up the oil—it literally pulverised it—to the greatest advantage and efficiency in combustion; and there was another important feature in connection with the use of steam, and that was that it very materially reduced the carbonised deposit, which, under ordinary circum-



A.—Flue for Fumes of Alloys.
B.—Flue for Products of Combustion.
C.—Opening for inserting Sprayer.

Fig. 37.-Crucible Furnace for Oil Fuel

stances, formed on the lips of the sprayer, choking it up. When air was used in the sprayer instead of steam, it was productive of greater local heating, certainly to be avoided. Many users of petroleum found it necessary to introduce heavy brickwork to prevent damage by intense local heating, but such brickwork, particularly in a marine boiler, was an objectionable feature, and to be avoided when possible. Some eight or nine years ago he fitted to a steamer having two single-ended boilers, an apparatus to supply vaporised petroleum through tubes in the back of the boilers direct into the combustion chambers, in conjunction with his system of forced draught. An illustration, showing a part of this arrangement, was given at the end of the paper on "Combustion,"

&c., which he read before the Institution, November, 1892. Petroleum oil passed from a closed reservoir in an elevated position through a coil in the uptake or funnel, where it was gasified or vaporised by the heat of the waste gases, and under its own pressure entered the combustion chamber at considerable velocity, in combination with air supplied under pressure. For this purpose refined petroleum had to be used, as refuse petroleum would have given a carbonised deposit in the vaporising pipes and soon have choked them up. Petroleum was a mechanical combination of several oils whose specific gravity varied considerably, and likewise their evaporative temperature: this had a strong bearing upon vaporising in pipes, and materially added to the danger in using such vapour. For instance, the slightest joint leak gave a gas which immediately fired, and it was extremely difficult to make and maintain tight joints under petroleum vapour under pressure. Scientifically and mechanically, petroleum as a fuel was a perfect success, but the whole question resolved itself into a commercial question, and he failed to see that it was possible to use petroleum instead of coals in the number of steamers trading from this country. Petroleum could not in this country be bought at a price that would compete with coal, and if there was any great demand for it the price would enormously increase, although there was abundance of oil in many parts of America and Russia.

Mr. J. DUCKITT (Secretary) explained that at the last meeting Mr. Weir was asked to submit a drawing of the furnace to which he alluded in the manufacture of iron, following upon a question by Mr. Seaman. Mr. Weir had not been able to prepare the drawing for that meeting, but a sketch of it would be found in a paper read by Harrison Aydon before the Institution of Civil Engineers in 1878, and included in Vol. 52 of the "Transactions" of that Society.

Mr. ROBERT WALLIS, in reply to the discussion, referred first of all to Mr. Weir's questions. The most striking one, he thought, was that where he compared the value or cost of running a ship with coal and with oil. Mr. Weir had taken the cost of bunker coals at 8s. 6d.—that was, of course, bunker coals at their own door—and had omitted to add to that anything for trimming or leading them. If they were to take the figure more like the average for bunker coals, say 12s. a ton, then the comparison altered in favour of oil. Mr. Weir's 600 tons, then, at 12s., would be £360; six men at £4 a month, though in a comparison with this they must add on to the wages the cost of the keep of those men, say six men at £5 per month, that would give them £30 in place of Mr. Weir's £24; the repair of fire tools, if it were worked out, would come out rather more than the £10—£15 per month would be more like the figure—a total of £405. Take Mr. Weir's price for oil, &c., £524; then they made on 300 tons of extra cargo at 10s. a ton, £150, which gave the comparative cost, £374—a difference of £31 per month in favour of oil burning. In further remarks,

Mr. WALLIS said they were dealing with things as they were; but the whole question of cost of oil and coal depended upon where the ship was trading. If the ship was trading to a port where oil could be obtained, then, undoubtedly, the oil was cheapest; if the vessel was trading from such a country as England, where coal was cheap, then, in the present state of supply and cost, coal would be the cheapest without any doubt. Mr. Weir mentioned the amount of steam required to drive the donkey for the service. He thought he would find if he tested one of these donkeys that the amount to drive it would be so small as to be practically neglected, for the donkey all through would exhaust to the condenser, and a very small quantity of steam would suffice to drive it—merely the vacuum in the cylinders. The matter of insurance was another question raised in connection with the carrying of petroleum in place of coal. He (Mr. Wallis) did not think, when the whole thing settled down, that would be greater than at present, for the fear of explosions from oil gas was not so much to be dreaded as might be imagined. The character of the oil which was used as a fuel was one with a very high flash point, and consequently the amount of gas generated from oil of this character was very small. Members would see the differences in the specimens on the platform. Wear and tear of the boilers was another question raised; but wear and tear with liquid fuel was less than when using coal, for, when using the sprayer, the heat generated in the furnace was a constant one, and the amount of air admitted was only slightly above that required for combustion, and there was no cooling down of any part of the furnace by the opening of fire doors as there was in the coal system. Then the wear and tear on the boiler would be less than that of coal. The arrangement of the brickwork was raised by Mr. Weir and several other gentlemen. Well, the arrangement of brickwork depended to a great extent upon the size of furnace they were using and also the character of the boiler. Mr. Urquhart, in his paper before the Institution of Mechanical Engineers, described several methods of brickwork as adopted in locomotives, and the Baldwin Company, of America, showed several forms of brickwork in locomotive work. He found the brickwork did not vary very much from that of the ordinary brick arch, with the exception that it had an additional wall. In the case of the ordinary marine boilers, what was required was to place the brickwork so as to baffle the flame and prevent it striking through to the combustion chamber. The exact pattern of that brickwork would vary under various circumstances and special requirements of any particular boiler. The lining of the bottom of the furnace enabled the circulation at the bottom of the boiler to be improved, and at the same time, if their burner was working badly, any drop of oil not sprayed fell quite finely on the bottom, it was at once burnt on the hot bricks, without which they would have an accumulation of coke on their furnace bottom. Mr. De Rusett asked if the oil could be carried in the ordinary double bottom of a vessel. He did not see any reason why it should not, and one vessel which they had fitted with oil-burning appliances went out to Peru and carried her bunkers in the double bottom. As far as he could learn they found no disadvantage or trouble in that arrangement. Mr. De Rusett also asked the question as to the flashing point of crude oil. It varied considerably. They might get it as low as 30° or 40°, or it might go up to 400° or 500°. It depended upon where the oil came from and the density of any particular well. He also asked about the power absorbed by the evaporator in making up the water lost in steam for the sprayers. The loss of water in the boilers was not a great deal if, as recommended by a great many people, the vapour from their evaporator was carried to the hot well and they used their evaporator practically as a feed-heater. Mr. Seaman also asked a question about the cost of repairs, that, as he had mentioned before, would be less with the oil firing. Mr. Fothergill raised a question about the tightness of bunkers. As far as he knew, and as far as he had seen with the ships they had fitted, they had no great difficulty with the bunkers. The greatest difficulty was, the ship was not a new one, and they had some trouble in getting the surface of the plate at the door smooth enough on which to make a joint; the difficulty was in making the joint tight owing to the plate being eaten away by corrosion. Mr. Fothergill mentioned about evaporating oil, and burning it as a gas. Using commercial petroleum would, he dared say, some day or other, cause an explosion. There would be some danger attached to it, but evaporating petroleum refuse would possibly work out all right as long as their appliances kept free from heavy tar deposit and carbon, which would inevitably follow, the apparatus would then get clogged up, and the trouble would be to clean it. In some experiments they tried evaporation—partial evaporation—sufficient to make gas to drive their burners in place of steam, and as far as their experiments went it was successful, but it was not a thing he should like to go to sea with; the whole thing got uncomfortably hot, there was the trouble with the tarry deposits, the oil they were using was a heavy oil to commence with, and there was always a tendency, with a tarry heavy deposit, to form coke in the furnace. The effect of high-pressure steam was mentioned by Mr. Fothergill, and was very clearly evidenced in their experiments. The cubic capacity of air required to spray a given quantity of oil they found very much greater than the cubical capacity of steam to do the same work. The steam seemed to pulverise the oil easier and more perfectly than air, and that was what led him to make the statement he did in the paper, that the amount of air required to spray oil was very much more than the amount of steam; consequently, when using compressed air, the air compressing plant, with a steamer of any dimensions or any number of boilers, would be considerable. Mr. Fothergill mentioned the brickwork in a furnace, and its bad effect. In an oil fire furnace the brickwork had a very good effect in that it retained a certain amount of heat in the furnace after the burners were extinguished, and so allowed the whole boiler cooling down gradually, and preventing any undue stress upon any part. The carbonising of the oil at the mouth of the burners was another point raised. That took place in all burners, more or less, less in the steam than in air burners; but still it took place, and that was the greatest difficulty in the cleaning. Where a burner or sprayer was not readily taken apart there they would have the most trouble. Consequently, it was essential, as pointed out, that burners or sprayers should be easily taken apart for cleaning, and then they could get over this difficulty of carbonised oil. It gave them little trouble if they could take their sprayer apart for half a minute, and put it together again at once, and in the one shown the furnace would not be stopped for more than four or five minutes. In concluding, he thanked those gentlemen who had said so many flattering things regarding the paper, and for the interest taken in regard to oil fuel.

The PRESIDENT thought the only thing that remained for them was to accord a very hearty vote of thanks to Mr. Wallis for his very able paper. He should have wished very much that there had been more speakers to deal with such an important subject as the burning or use of liquid fuel. It had now reached a stage beyond that of mere conjecture. There was not a doubt that if liquid fuel could be had at a reasonable price there was no difficulty whatever in burning it in a thoroughly efficient and economical manner. This was clearly demonstrated on the Caspian Sea, where there was not such a thing as a steamer burning anything else than the refuse of petroleum (astatki). Mr. Fothergill had referred to different kinds of oil, and the great danger attached to their use. There was a difference, of course, between the kinds of oil. There were three kinds. Firstly, refined petroleum, scarcely used at all, and that was the kind with which there was, perhaps, the greatest danger. Then they had the crude petroleum, just as it came out of the earth, which would be dangerous because it contained all the naphthas, benzenes, and so on, very light and highly inflammable; but the custom in hot countries, where the oil was usually found, was to expose the crude oil in open tanks and let the sun evaporate the lighter carbons, so that the resultant could be used with perfect safety. As regarded the third kind of fuel (astatki), exclusively used on the Caspian Sea, it was of a heavy, treacly description, and not at all dangerous. It could be carried in any part of the vessel, so to speak, either in cross bunkers or side bunkers, or in the double bottom; and it had been suggested in some cases, where there was a large compartment, to prevent the oil coursing about when half full, to allow the sea water to flow in and keep the tank always full. There was no difficulty about that if circumstances required it. Mr. Fothergill was somewhat sceptical about making bunkers tight enough. In new ships there was not the slightest difficulty; every tank in a steamer was subjected to a high pressure—more so than boilers were thirty or forty years ago—without any place or rivet leaking in the whole bunker. He thought he could only repeat that the use of oil fuel was reduced to a certainty, and it was only a question of cost. Where it could be had at anything like a reasonable price it could be used, for it presented such enormous advantages. They had a better flame, a more constant supply of heat; there was no opening and shutting of furnace doors, no difficulty in trimming the bunkers, as the oil found its own way into the holes and corners. There was, moreover, no difficulty in getting it out, and very often this was done by gravitation, but where the bunker was below the boiler it was necessary to have a pump and service tank: they had often put the bunkers above the level of the furnaces, and had no difficulty. Among other advantages, they eliminated the firemen, they minimised manual labour, and altogether there could not be a doubt that the use of liquid fuel was one that would surely come in wherever the supply of the oil could be had at a reasonable price. He now asked them to carry by acclamation a hearty vote of thanks to Mr. Wallis for his very able paper.

The resolution was passed accordingly.

THE application of electricity to the working of the Leeds tramcars has made such good progress that it is expected they will be ready for use in August. The route is between Roundhay and Kirkstall. The six miles of double lines are practically completed, the overhead wires have been put in position, and the cars are about ready. The engines and dynamos will be ready to supply the power necessary to propel the cars. The Hull Corporation are contemplating the reconstruction of their tramway system, and the laying down of wood pavement at an estimated cost of £272,000.

MORE CANDID CRITICISMS.

In the course of an article on the collapse of *The Engineer's* competition the *Electrical Review* says:—Now that *The Engineer* competition is over our contemporary's columns are being filled with the very natural protest consequent upon the remarks as to the absolute non-existence of a motor-car industry in England. The Daimler Company contradict this flatly, and state they are making three cars weekly, and have 200 men employed. *The Engineer* gibes at 200 men turning out but three cars per week, and the wage account can scarcely be termed moderate. But, perhaps, *The Engineer* never helped to start a new business? Those who have done so will easily understand that the wage account does total up in a most unaccountable manner. Even the people from whom you buy stores look on you as fair prey to be pillaged, and the difficulty in getting around one a suitable and satisfactory set of men is, at times, most disheartening. We by no means consider that *The Engineer* is fair, even though the motor-car industry be very small. *The Engineer* repeats its assertion that light oil vehicles were admitted, and upon very liberal lines. Mr. Moore, of the Motor-Car Club, however, quotes *The Engineer* itself:—"In the first instance we excluded vehicles propelled by light oil or petroleum spirit," and there seems to be little doubt that these vehicles were excluded from the competition. Mr. Moore also objects to the demand for six sets of drawings of each machine. There were only three judges, and six sets of drawings was obviously a big demand. For whose use were they required? Our contemporary finds fault with Mr. Sturney when he claims that the Daimler Company's working drawings have cost them thousands of pounds. They might soon cost that if many sets of six were required. Mr. Sturney distinctly states that the Daimler Company are full of orders, have vans working in London, several carriages in Scotland, a van in Manchester, and some 20 in all in the hands of the public, and all giving satisfaction. *The Engineer* continues to rail at the Daimler Company, especially as regards a turnover at the rate of £50,000 per annum. Now, is this fair? If the Daimler Company is turning over this much already it is not doing so very badly. There may be no motor-car industry, but to refuse cognisance to the at present biggest portion of the industry, and then deny the existence of the industry is not right. If the competition arranged by *The Engineer* had been more liberally framed, so as to have given no substantial peg on which to hang any complaint of unfairness, we think it would have been of far more use to the public. If light oil vehicles are not suitable, let this fact be plainly made evident. But to rule them out without a chance, and put them on only in a side show is to beg the whole question, and leave the door open for any Motor-Car Club man to complain. The spirit-driven car is not a sweet machine. It vibrates badly when not running, and, as made in France, is open to much criticism as to workmanship. It may, and sometimes does, blaze up, and make itself a nuisance, just as horses do when they fall down and kick and plunge on the ground. But the spirit-driven car can run miles and miles on end with a small quantity of fluid and a little fresh cooling water to replenish its tanks. In these respects it is a success. A commercial traveller in Surrey, Kent, and Sussex, who possessed a motor-car of this type could save many hours of valuable time as compared with South country railroads, both in actual time on the road and in weary hours of waiting for the slow trains at long intervals. We do not care two pins for the company promoters who have seriously damaged the motor-car industry, but we do wish to see the light oil car get a fair trial. Once get motor-cars of any type into commercial use and the way is paved for other cars. It would be satisfactory to see the spirit car helping the electric accumulator car to charge up at night, and there is no reason why it should not do so. We observe that *Engineering* follows *The Engineer* in all its criticisms, and denies equally the existence of a motor-car industry, and echoes its quondam bitter enemy to the tune that there is no thoroughly satisfactory self-propelled vehicle. If it comes to this, there is no thoroughly satisfactory horse, and the possession of a horse and the driving thereof are not unmixed blessings. To many people even the smell of a few hundred motor-cars would be less unpleasant and far less unhealthy than the effluvium due to horses, especially on wooden pavement in a hot city. Yet horses have been bred for man's use for thousands of years and have not been cured of their habits. The motor-car is ordered to be thoroughly satisfactory from the start. It has not yet had time to purge itself of the taint of the promoter, and the present poor condition of the industry has arisen because of the promoter and his burdens. Our contemporary, *The Engineer*, surely cannot forget that it was made to figure as supporting the most blatant of many very curious productions of the prospectus order. *Engineering* backs its opinion by reference to the competition at Crewe under the auspices of the Royal Agricultural Society. Here, again, only three entries were made, and but one vehicle turned up. We have no particulars of the conditions in this latter case, and cannot say whether there is as good an excuse in this as in *The Engineer* competition for non-competition. We repeat, however, that if the new industry is worth fostering there must be some liberal allowances made at the beginning. Instead, *Engineering* hints at tramcars carrying their own motive power without nuisance to passengers or to the public, as though at present horse-traction were of this type. Now we do not hesitate to say that the exhaust of a spirit engine, or even of a heavy oil engine, when in order, is preferable to the wastes of an animal. Moreover, the one is merely transitory, and dissipated with no further results; the other remains a nuisance, has to be removed at some expense, and what remains to be dried and scattered by the wind is a disgusting irritant to the eyes and lungs that no self-respecting community would tolerate if it could help doing so.

THE RESISTANCE OF VEHICLES ON COMMON ROADS.

The United States Department of Agriculture has recently carried out a series of traction experiments on roads of various descriptions, and an account of these appear in the *Engineering News*, to whom we are indebted for the accompanying abstract:—

"The first experiments were made on the roads of the United States Road Exhibit at the Cotton States and International Exposition in Atlanta, in 1895, consisting of a modern macadam, a sand and an ordinary dirt road. The manner of making these roads is described, and the traction experiments were made with a heavy farm wagon loaded with cotton bales. The amount of pull exerted at any time was indicated by a specially designed tractometer (*see* Fig. 1). In this device the amount of force exerted by the team was weighed by the spring, S, in compression, and was indicated on the arc, A, by means of the pointer, P. The smaller spring was sufficient for all forces below 600 lbs., and the larger spring came into play after this mark was reached. The arc shows above the backs of the horses and was marked in large figures. No precaution was taken to check or lessen the oscillations of the index arm beyond that of making the parts fit snugly. There was thus no lost motion, and all oscillations recorded the variation in the amount of pull. Though these conditions made it impossible to read the scale accurately, it indicated the true state of affairs, which was as follows:—

"On the smoothest possible macadam road surface the force of traction was not constant, but changed continually within a range of 50 lbs.

"On the ordinary dirt road the force varied from absolute zero to 700 lbs.—in a gross load of 3,000 lbs.—becoming in effect a rapid succession of violent jerks.

"On heavy grades in the case of the smooth road the force was more nearly constant. On a smooth road the force necessary to start a load was four times as great as the force required to draw the load at a uniformly slow pace when started, and was one-tenth the gross load. The force required to start a load on a dirt road was about one-fourth the gross load, or not greatly in excess of the upper limit of the tractive force when the wagon was in motion. From these observations the following conclusions were drawn :—

"A team harnessed in the ordinary way is subjected to a continuous jerking motion, which on even the smoothest country road is enough to greatly increase the fatigue. On a dirt road in bad condition this jerking motion becomes a succession of heavy blows transmitted to the animals by means of the collar. The fatiguing effect of these blows is probably double that of a steady pull equal to the maximum figure reached in the oscillations, and they further bruise the shoulders of the team. Starting a heavy load is also equivalent to a violent blow, as the driver ordinarily draws his team well back and then urges it suddenly forward against the collar held by rigid traces.

"The smoother the road the more nearly constant will be the tractive force and the less the fatigue for the same amount of work. And if a load four times as great can be drawn over a smooth road as over a rough one, by exerting the same amount of force, then a team can haul four times as much in the same time over the smooth road and suffer less fatigue in the

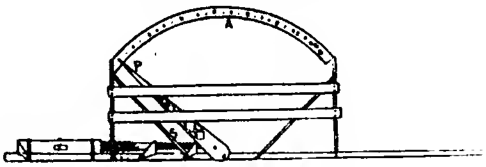


Fig 1.—Tractometer.

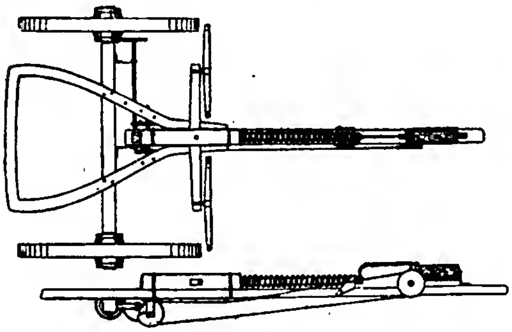

Fig. 2—Tractograph

operation. Mr. Neely, under whom the experiments were conducted, thinks that some method should be adopted for making an elastic connection between the wagon and the team, thus gradually transmitting the shocks at the wheel rims to the team. He says that at Atlanta a team of small mules readily drew 12 bales of 500 lbs. each, on a heavy Studebaker wagon up a 10 per cent. grade on the macadam road, with the tractometer indicating a pull of 1,000 lbs. The same team was completely stalled in going down the 6 per cent. grade on the sand road, with an indicated pull of 1,900 lbs. Nine bales of cotton were removed before the team could be again started. The driver refused to venture upon the dirt road with the 12-bale load.

"To demonstrate the practical advantage of wide over narrow tyres, the following test was made :—A piece of clay road was made thoroughly wet, and over one portion a heavily-loaded wagon with 2-inch tyres was rapidly drawn, and over the other portion an equally heavy wagon with 4-inch and 5-inch tyres was drawn the same number of times. In the latter case the front axle was shorter than the rear axle, so that the wheels did not run in the same track. The result was that the narrow tyre cut the road into ruts several inches deep, while the broad tyres rolled the road into a smooth surface. The tractometer showed that twice as much pull was necessary to draw the same load over the half-road cut by the narrow tyres.

"In order to obtain results which would be accurate and of scientific value, a tractograph was devised to record the pull automatically. This apparatus was similar in principle to that used in securing indicator diagrams, and is shown in Fig. 2. A long arm, holding a pencil at the end, was attached to the end of the piston which previously moved the pointer in the tractometer. The pencil point rested on a revolving cylinder extending along the wagon pole, and the cylinder was revolved by means of the gear, driven directly by one of the front wheels of the wagon. A single long spring was substituted for the two short springs previously used.

"Any pull exerted at the double-trees would compress the spring and cause the pencil to move forward along the cylinder, and as the cylinder revolved as the wagon moved forward, a continuous record of the force exerted was thus recorded on the paper. The tractograph was graduated in pounds by placing weights on a platform connected to the double-trees by a rope and pulley. The scale was made to 10,016 intervals up to 1,200 lbs. ; and from this data sheets were ruled and spaced to 1,016 pulls. As the cylinder revolved once in a forward movement of 1,316 feet, the sheet was ruled transversely into spaces corresponding to 100 feet.

"Experiments were made with this instrument, and diagrams are given for results obtained on a level asphalt street, on a level macadam, a level dirt road, and on a macadam road on a 10 per cent. up-grade. The two first show a generally even range of oscillations, with an average pull of about 50 lbs. in the first case and 100 lbs. in the second. The dirt road was dry, smooth, and firm ; but the pull runs up from 100 lbs. to 500 lbs. with rapid changes, and the general result is a draught of about two and a half times that required on a macadam road. In the case of the hill the record shows very wide oscillations caused by the fact that the team required constant urging. It required nearly seven times as much effort to draw the load up the 10 per cent. grade as on the level highway.

"The tractive force is taken as signifying the force required to draw one ton of 2,000 lbs. On this basis the following is the record for these four experiments :—

Road.	Tractive force.
Asphalt, level, poor condition	26 lbs.
Macadam, level, good condition	38 „
Dirt road, level, good condition	96 „
Macadam, 10 per cent. up-grade	236 „

"Mr. Neely, who carried out the experiment, compares these with the results for the best macadam roadways as tabulated by Mr. Rudolph Hering, M. Am. Soc. C.E. :—

Authority.	Tractive force.
Navier	45 lbs.
McNeill	46 „
Rumford	50 „
Gordon	37½ „
Morin	32 „
Office of Road Inquiry	38 „
Average	41 „

"The following general results are obtained from the experiments made by the engineers above mentioned :—

"The force of traction varies universally as the diameter of the wheel, and increases with the speed, upon hard roads, but is not in proportion with the velocity. The width of tyres is found to have no effect on the traction on hard roads ; but this width has a very decided effect upon the condition of the road surface and on the cost of maintenance. The effect of inclination of surface is a matter of mathematical computation, and can always be figured by the following formula :—

"$R = F + a\,W$ where

"F = Force required to draw the load on a level.

"a = The grade expressed by a fraction.

"W = The weight of the load in pounds.

"R = Force required to draw the load up the incline.

"An appendix to the bulletin contains various tables taken from Sir John McNeill, Morin, Mr. Rudolph Hering, and from experiments made by the Office of Road Inquiry."

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.

All Advertisements should be sent to the Advertising Department, F. King and Co., Limited, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. King and Co., Limited, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

SPECIAL NOTICE.

The Automotor and Horseless Vehicle Journal *can be obtained from all* Messrs. W. H. Smith and Son's *bookstalls, and the following Agents:—*

London: Pottle and Sons, 14 and 15, Royal Exchange, E.C.
Wholesale: Brett and Co., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. McCann, 37, Union Street.
Manchester: John Heywood, Deansgate.
Newcastle-on-Tyne: C. C. Ross, 35, Side.
Paris: Homère Moreau, 97, Rue Nollet.
Victoria (Australia): Phillips, Ormonde, and Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

JULY 15th, 1897.

ANSWERS TO CORRESPONDENTS.

Molas (South Tottenham).—A motor-tricycle, weighing under one ton unladen, is not subject to any special Inland Revenue duty under the new Locomotives on Highways Act, 1896. The only amount payable is the ordinary Inland Revenue carriage license of 15s. per annum, procurable at any post-office.

J. Herrmunn (Streatham).—You cannot do better than submit the whole of your invention to a first-class firm like Messrs. New and Mayne, Palace Chambers, Westminster, who would give it the very best attention, and, if suitable, take it up and work it.

R. M. S. (Fleet, Hants).—We hope later to inspect the car you mention, and can then give you advice you seek. At present, as our technical editor has not personally had an opportunity of judging the vehicle, we are not prepared to advise a purchase.

Motorenfabrik (Switzerland).—Your best plan is to apply to one of the first-class English engineers, who will no doubt be glad to make an arrangement with you if your patent is of commercial value. You will find several good names in our advertising columns.

R. A. F. (Wath en Dearne).—We know of no English translation of the "Manuel Practique du Conducteur d'Automobile."

THE AUTOMOTOR INDUSTRY AND HOW TO FOSTER IT.

WHEN the dynamo emerged from the laboratory and electric lighting became a commercial possibility, what should have been a perfectly legitimate industry was converted into a huge means of defrauding the public. The scandal was so great that not only was the development of electric lighting seriously hindered, but an Act of Parliament was passed for the protection of the public of such severity that it was found in many cases to absolutely prohibit practically the use of electricity. Even now the person or company who wishes to introduce electric lighting to any locality finds the various legal obstacles in the way by no means easy to surmount. There must in all cases be absolutely *boná fides* and the necessary capital. This, of course, is all with a view to prevent the operations of the Company promoter, Trust and Financial Corporations, who go about seeking what industry they may devour. With the introduction of the motor-car we have seen a somewhat similar financial phenomenon to that which attended the birth of the dynamo, and with somewhat similar results, although of less intensity. We do not gather that those who have invested in the numerous Motor Syndicates, Companies, and so forth, are rejoicing very much. Their money has been for the most part sunk in "master patents" of but doubtful and limited value, and the recent Competitions have not served to greatly impress the public with the future of the motor-car industry; in fact, there is a distinct "slump" in motor shares. For our own part, so long as the losses fall upon Company promoters and those who are like unto them, we are not sorry that events have not turned out so fortunately as was anticipated, and hence we regard the recent Competitions as a much-needed and salutary "eye-opener," if such a term is permissible. What we have to do now is to educate public opinion on the automotor question—to show that, apart from the fictional *ballons d'essai* of the prospectus writer, there is a legitimate field for investment in the motor-car industry, provided that the advantages and limitations for the employment of automotors as against horses are well appreciated and understood. For example, in Yorkshire, Derbyshire, Cumberland, and in many parts of Scotland the roads are atrocious and horseflesh and labour cheap. No commercial advantage at present would accrue from an attempt to place a motor-car in such districts in competition with horse coaches or wagons. In the South, around London, the roads are good, horseflesh and labour comparatively dearer. Such services as parcel distribution, omnibus and cab working could undoubtedly be successfully undertaken with one or two of existing types of motors. Again, both the investor and the person who uses a van or light cart in his business are inclined —not without reason—to fight shy of motor-vans, and this, of course, reacts against the manufacturer of automotors. With a view, then, of educating the public on this question, and removing prejudice, we make the following suggestion, and invite our readers to express their opinion on it.

We propose that in London and the large provincial cities, such as Liverpool, Glasgow, Manchester, Birmingham, &c., there should be formed Automotor Exchanges—that is, manufacturers and designers of automotors should form a parent Association, with branches in these towns. At each branch there would be a depôt, with examples of each type of motor. A would-be purchaser would thus be able to inspect the whole industry at a glance, and obtain the fullest technical information. Trials could be arranged, and purchases effected with the least trouble, and with the best possible guarantee that the purchaser had obtained what he required. A trial might well be made of this idea in London to start with. It is, of course, not intended to have anything in the nature of, or savouring of, an "Exhibition." Our idea is that of a purely business Exchange, where one could see samples of motors and obtain quotations exactly in the same way as one can go into the Corn or Wool Exchange and obtain samples and prices of these articles. The nucleus of such an Exchange as we have indicated already exists in the shape of the Self-Propelled Traffic Association. At present this body cannot be charged with having effected very much. It has certainly been the means of adding greatly to the literature of the automotor, and some very excellent papers have been produced under its auspices. We take it, however, that the literature is now fairly copious, and it remains with the members of the Association to effect something practical. True, the Association has offered prizes and encouraged designers, but this hardly meets the case. We would suggest to the Association whether it could not see its way to establish an Exchange on lines such as we have indicated. Manufacturers and engineers can hardly be expected to compete in the production of the "best" automotor, but they would, we think, support an Exchange where the purchaser could exercise his choice, because, after all, it is he who is the final judge.

TRAFFIC IN THE CITY.

IF there is one reason more cogent than another for the employment of automotors it is to be found in the congested traffic in London. From early morn till midnight, from Hyde Park corner in the West to Poplar in the East, and from Islington in the North to Brixton in the South, and even beyond these limits, there is a heavy stream of traffic which, approaching the City, becomes of such density that only by the most careful police regulation is it possible to conduct it at all. It is to foreigners one of the most wonderful sights—the regulation of the London traffic; but after all, the capacity for traffic of our streets is limited; in few streets is there room for more than two tracks, and an accident, such as a horse falling down, will create a block which may be felt half a mile away. Indeed, the congestion of the metropolitan traffic threatens to become in the near future a most difficult problem for solution at the hands of the County Council and the City Corporation. Spasmodically the Press draws attention to it through the complaint of some belated traveller losing his train in consequence of his cab or omnibus having to wait at a block. Sanguine and unsophisticated is he who at any time during the day thinks he can by "cabbing it" go from, say, the Mansion House to the Law Courts in 20 minutes. There is, in fact, but little saving of time effected, no matter how high spirited is the horse and how skilful is the Jehu. So heavy is the traffic at many points that unless it be stopped by a policeman it is exceedingly dangerous to attempt to cross the streets. As "Dagonet" well puts it in a recent number of the *Referee*, "the traffic of London ought to be completely reorganised. It has increased to such an extent that it is beyond control and is perpetually in a state of confusion." In the Strand or Cheapside we see cabs, omnibuses, heavy railway vans, mail carts, costers' barrows, all mixed up together, and for often considerable periods of time the pace of the whole will be regulated by some heavy, slow moving vehicle that heads the procession. To dilate upon this state of things is of little use; the facts are too apparent. The question is, how can they be remedied? In the first place the vehicles should be classified, and, as far as possible, should be obliged to traverse routes accordingly. As "Dagonet" points out there ought to be a means of limiting the number of buses running along a narrow thoroughfare, and of compelling the heavy van traffic to make use of roads off the main artery. Supposing, however, this was effected it would not greatly assist us because a heavy railway van delivering rolls of paper to a Fleet Street office would, as at present, create a more or less pronounced hindrance to traffic. If, however, we could reduce the length over all of the space occupied by a horse-drawn vehicle we should increase the capacity for traffic of a street by the same amount. Obviously this can only be accomplished by eliminating the horses. Of the length occupied by an omnibus fully one-half is used for propulsion, while in ordinary carts quite two-thirds of this length is so utilised. In very heavy vehicles such as brewers', coal, flour, and market wagons, drawn tandem, two horses abreast, the same proportion obtains. In tramcars the horses occupy about one-third of the length. It follows that our streets are so congested because the animals used for traction occupy such a large proportion of the space. To see how crude and unsatisfactory is horse traction we need only glance at the railways. In ordinary trains the locomotive will occupy but about one-tenth to one-fifth of the length.

Were horses largely eliminated from the principal thoroughfares the gain or saving would be enormous. The traffic could be largely increased without inconvenience. There would be less risk of life and limb, and less necessity for regulation. Also the cost of maintenance of the roadway would be less because (notwithstanding that a high authority has declared to the contrary), it is after all the hammer-like action of the horses' feet that in time wears out granite setts, a fact which is very palpable on London Bridge. From a hygienic point of view the gain would be incalculable. At present the street orderly bin is a necessity. An army of small boys finds constant occupation in gathering up the ordure of the horses, and a large number of carts and men are required to empty the bins and transfer their contents to barges. In fact, what to do with our street sweepings is an ever anxious subject to the municipal authorities. In warm weather, especially on windy days, the air in the streets is charged with fine particles of desiccated filth.

A reformation in the method of traction is the only possible solution. We must, at all costs, and for every reason, eliminate the horse from our crowded streets and substitute for it the automotor.

CONTRACT FOR MOTOR-CARS.

The Central Engineering Works Company (Limited), of York, have received a contract from Messrs. F. G. Von Hillenschmidt and Co., of Warsaw, for four of their patent motor vehicles, to be built for two, eight, ten, and twelve passengers respectively. the larger ones to have light luggage cars attached, suitable for touring purposes. These vehicles will be fitted with the patent cork and rubber tyres, invented by Mr. P. Appleyard, Grafton House, Halifax, director of the Company. The Central Engineering Works Company (Limited) is being reconstructed with a capital of £30,000, to enable it to cope with the nominal increase of business, the firm having had during the last few months to decline orders to the value of over £50,000.

CONTINENTAL NOTES.

The French Senate has doubled the "Octroi" tax on cycles, motors, &c., entering Paris. In vain does *Les Sports* proclaim the fact that "We live in France under a democratic *régime*." That may be so, but all the same the gay Parisians have now got to pay 20 francs per year instead of 10. *Les Sports* talks about petitions and what not; but is it not a cardinal principle of democracy to tax the luxuries of the rich?—and one must be at least removed from poverty by a good step in order to keep a "bike."

Really this tax reminds us of Harcourt's van and wheel tax, which our people would not have at any price *at that time*; but directly automotors were legalised our Chancellor of the Exchequer "taxed" our motor-cars to the tune of two guineas, or about 43 francs per year; so our French neighbours have got off rather well.

The petition in favour of a remission of the "Octroi" tax is being got up by L'Union Velocipedique de France and by our esteemed contemporary *Les Sports*. We do not, however, think that they will succeed in their object. Government are always in want of money, and so far as our Governments is concerned, so long as it does not touch the poor man's beer and 'baccy, it can tax anything.

In order to give due emphasis to the petition, our contemporary and L'Union Velocipedique will give two gold medals to the two cyclists who obtain the most signatures to the petition.

The Automobile Club de France has lately demanded the resignation of a member who brought into the club a lady who was neither his wife, nor his sister, nor his daughter. It seems that there is a rule forbidding the use of the club to members' "friends." We congratulate the club on its "respectability."

A movement is on foot to assimilate the French law regarding automotors to that already governing tramways so that enterprises of a commercial nature shall be entitled to State subvention as are tramways. Something like 1,100,000 francs is given to French Tramway Companies as subvention, and in many districts automotors could be employed where it would not pay to lay tram lines or railways.

At Longchamps a steam omnibus on the Dion-Bouton system and capable of carrying 23 passengers has commenced to run regularly.

The Peugeot motor has been so successful that a company has been formed to manufacture it on a large scale. Premises have been taken in the village of d'Audincourt and over 180 persons are continually employed in the manufacture of this type of automotor. Evidently there *is* a motor-car industry in France if not in England. Next month about 280 to 300 hands will be taken on.

M. Léon Bollée was the winner of the coupe de motor-cycles, gaining the prize offered by M. Le Baron de Zuylen.

The Paris Omnibus Company has adopted the Serpollet automotor upon the Cimetière de Saint Ouen-Bastille Line. The Bon Marché, of Paris, uses motor-cars as parcels' delivery vans.

Some Forthcoming Events.—July 24th: Paris to Dieppe race for carriages and motor-cycles; August 5th to 11th: Heavy weight competition at Versailles; August 22nd: Paris to Coburg race for motor-cycles.

President	SIR DAVID SALOMONS, Bart.
Secretary	ANDREW W. BARR, Esq.
President of the Liverpool Centre	The EARL OF DERBY, G.C.B.
Hon. Local Secretary	E. SHRAPNELL SMITH, Esq.

WE understand special arrangements are being concluded for members of the Self-Propelled Traffic Association to visit the forthcoming motor-car race from Paris to Dieppe on July 24th, and the Paris Heavy Vehicle Competition on August 5th, organised by the Automobile Club of France. Full particulars can be obtained from the Secretary, at 30, Moorgate Street, London, E.C.

AT a Special Meeting of the Liverpool Local Council of the Self-Propelled Traffic Association, held on Tuesday last, to discuss the forthcoming Motor Vehicle Exhibition and competitive trials being organised under the auspices of the Association, it was decided to postpone the issue of any particulars pending a report by a deputation of the Council then selected to attend the Heavy Vehicle trials at Paris, which are to be held on August 5th, 6th, and 7th next.

AUTOMOTORS AT THE ROYAL AGRICULTURAL SOCIETY'S SHOW, MANCHESTER.

[BY OUR SPECIAL COMMISSIONER.]

IN our last issue we dealt with the trials held under the auspices of the Royal Agricultural Society, or, in other words, the working side. We now have to deal with the exhibition side.

To sum up the exhibits, with one or two exceptions, notably the stands of the Anglo-French Motor Company and the Lancashire Steam Motor Company, they were little short of disappointing to the majority, but most people seemed to have expected perfection in the salad days of a youthful industry, and forgetting that "Blessed is he that expects little, for when he gets it he will not be disappointed," some of their disappointment was courted.

Although at several stands the cars were not on view, chiefly through not being ready to be shown, it was surprising to find how many exhibits had some bearing on the industry, and how many of the exhibitors in all branches of the implement section were at work directly or indirectly on the development of the motor-car. For this reason the show contained much of interest to the intelligent visitor, but would prove a disappointment to the catalogue-bound curiosity-monger. To the latter the stands of the two firms previously mentioned afforded all that was worth seeing, with perhaps an extra dash of spice afforded by the daily run in the show ground of the Leyland van.

To pass on to the exhibits themselves, only a short way down the Central Avenue the stand of the ANGLO-FRENCH MOTOR CARRIAGE COMPANY (LIMITED), of London, Birmingham, and

Paris, was to be met with, and the constant crowd of sight-seers and questioners did much to arrest attention, to say nothing of the attractiveness of the Company's show of vehicles. These were four in uumber, and comprised two motor-cars for two and four persons (one of which we illustrate, Fig. 1); a motor-van for parcels fitted with double-cylinder motor, and friction and spur-driving gear; and also a shallow-sided motor-lorry, likewise illustrated (Fig. 2). The motor-carriages were specimens of the latest productions in motor-car building, having been built to the order of a client in London, while the lorry is destined to be used for the transport of jute bales by a Scotch firm. In all the vehicles special attention has beeu paid to the isolation of the motive power for the bodies of the cars, and this has been achieved with success by the full aud judicious use of rubber buffers or accumulators and steel springs. The much-complained of vibration is thus reduced to a vanishing point, or something very hard to otherwise describe. As objections have been raised from time to time on account of the alleged trouble of attending to the working parts of motors, it should be pointed out that in these cars the supply of oil to the motor is automatic, while the lubrication of the wearing parts is practically the same. The amount of attention needed is thereby reduced to a minimum. As far as the carriage bodies are concerned they are splendidly finished, the appearance and upholstery being equal to the best specimeus of coach-building and fitting in adjoining stands devoted entirely to the time-honoured horse-drawn vehicles.

As will be seen, the lorry is specially suited for the conveyance of bulky loads, the inside dimensions of the body being 11 feet by 4 feet 6 inches. It is propelled by a double-cylinder benzoline vapour motor, developing 8 to 10 H.P. The power is transmitted direct from the motor to the back axle by friction and spur gearing, which enables two speeds of

r and eight miles an hour to attained in a forward direction, l gives one reversing speed. It l be noted that the wheels are of the same size, being shod h steel tyres, and fitted with improved rigged axle-sheering trivance. Underneath is the ling water circulating apparatus cylinders being jacketed. The rage tank carries a supply of l for 50 miles, and the ignition rk is obtained from a 60 ampère-ır secondary battery. For very g distances an extra battery is › provided. As these batteries carried under the front seat y can always be got at easily for ıging or charging.

'he Lancashire Steam Motor ıpany, of Leyland, were running ir motor-van (Figs. 3 and 4) ly in the ground, and had the ısure of carrying several of the ›ility attending the show. Their ı was awarded a silver medal in Implement Section, and it is ısing to note that the judges l no hesitation in making the award, but, on the contrary, expressed their pleasure and willingness, as they considered it had been fully merited. Concerning the criticism we made on the steering gear in reporting the trial at Crewe, its behaviour naturally arrested the attention of the judges, and it is therefore most satisfactory to be able to say that after a further investigation of the steering and compensating gear at the end of the run they expressed themselves quite satisfied with both, as regards mechanical construction, and agreed that the trick the latter played in the trial was not of a nature to reflect at all upon their principle or construction. The small but irritating evil wss cured after the run, and the difficulty has not recurred again since. At their stand the firm were also showing a portable 6 B.H.P. engine and boiler which was very much the same as the motor and boiler used on the van. A smart feature of the exhibit was also a steam lawn mower. One man can work it, a single handle controlling the machine. The weight is also so disposed as to bear on the roller, thus rolling and cutting at once. The motor can be used separately by slipping the driving chain out of gear. A fire pump attachment was also shown at work.

Fig. 2.—Anglo-French Motor Carriage Company's Motor-Lorry.

Messrs. J. Petter and Sons, better known in the motor world as the Yeovil Motor Company, were showing a collection of petroleum motors, but they did not show any cars. The same was the case with Messrs. E. Foden, Sons, and Co. (Limited), of Sandbach, who have given considerable attention to the construction of motor vans, and, we believe, have achieved considerable success, but they confined their attention at the show to their well-known traction engines and road locomotors.

Another firm of motor-car builders, the Wolseley Sheep Shearing Machine Company, whose "Wolseley" autocar has already been illustrated in these columns (February, 1897, p. 186), had a stand, but were not showing the car. They devoted the back page of their pamphlet, however, to a view of the car, these pamphlets being freely distributed. The car is driven by a benzoline motor, and has one regulating handle which gives two speeds and a reverse motion. Messrs. Tallent and Co., of Manchester, were to have shown a four-wheeled dogcart, but it was not ready in time to be exhibited. The cart is fitted with cushion tyres, spider wheels, and ball bearings. The steering system is Ackerman's with some improvements, and is provided with independent brakes to the axle and tyres. The motor, which is petroleum driven, is made by Messrs. Urquhart and Bollé, of Liverpool, and 57, Barton Arcade, Manchester. It is of a comparatively new type, of which we hope to be able to give some further particulars later on. It is double cylindered and develops 3 H.P. The gearing gives four speeds in the forward direction and one backward speed. Messrs. Windover, Turril and Sons, of London, carriage builders, were not showing the motor-car referred to in the catalogue, and declined to give our commissioner any information concerning it beyond that they had made some private runs of a satisfactory nature.

In connection with sundries Messrs. Binney and Son, of Birmingham, &c., in a large collection of belts and driving bands, were showing some specially suitable for autocar purposes, while Messrs. Royce and Co. (Limited), of Manchester, included switches for starting, stopping, and reversing electric motors. In the course of conversation with those interested in motor matters it was gathered that Messrs. J. Holdsworth, a Liverpool firm, expected to have a four-seated motor-carriage on the market soon at a price considerably lower than that at which most cars are now being sold. A four-seated Victoria, running at 4 up to 25 miles an hour, has done well on its trial trips. Another local firm, Messrs. Simpson and Bodman, of Didsbury, near Manchester, have decided to abandon liquid fuel in favour of coke for their steam-driven vehicles.

IT is said that the roller-ship, "Ernest Bazin," has, after several trial trips, attained a speed of six knots. This compares very indifferently with the 37-knot speed expected by the inventor, but is probably nearer the average anticipation.

FIG. 3.—THE LANCASHIRE (LEYLAND) STEAM MOTOR COMPANY'S VAN (p. 418).

THE YACHTING AND FISHERIES EXHIBITION.

A SMALL but well-arranged exhibition of appliances used in yachting and fishing has been opened at the Imperial Institute, London, and those interested in nautical automobilism will find much to interest them. Perhaps the most striking exhibit is that of the Liquid Fuel Company, of Cowes, best known to our readers as the designers and builders of the Lifu motor-van. This Company shows a varied collection of beautifully finished steam launches using petroleum as fuel. They also show a full-sized model of their water-tube boiler and oil-burner, together with some remarkably well-finished sets of compound and three-stage expansion engines. Messrs. Priestman, of Hull, show a fine specimen of their oil-motor for launches, barges, &c.; this motor has been used all over the world and has given great satisfaction. It is found in the "fly-boats" of the Black Country and on the rivers of West Africa and Burmah. It has thus proved its reliability even in the hands of those who cannot be said to know anything of oil-motors whatever. What we like about this motor is its strength and solidity; there is no sacrifice of metal in order to reduce weight, and all the working parts are simple and "get-at-able." They are made in all sizes from 2 to 90 B.H.P. Like all oil-motors, however, they are uni-direction engines, and this necessitates the use of propellers with reversible blades. A Priestman oil-motor has been fitted to a large trawler, 82 feet by 22 feet by 11 feet draught; the motor gave off 90 H.P. and produced a speed of 8 knots, a result in marked contrast with that of the much vaunted steam-lifeboats, which we discuss elsewhere. So highly are these motors thought of that they are rapidly superseding horses for canal traffic. For motor-car purposes it is, of course, necessary that the weight of the motor should be kept low; the same remark applies to motors intended for electric lighting on board torpedo and other small craft, such as yachts. Mr. Mills, of Sunderland, has for some time past undertaken the production of aluminium castings, and at his stand he shows some very beautiful specimens of bed plates, crank chambers, &c. Aluminium seems particularly well adapted for this purpose. Its strength is about 16–20 tons tensile, and its specific gravity about 3; practically it is about one-third the weight of gun-metal and iron, and except for bearings it can replace these metals for all purposes in machinery. It does not rust and is untarnishable. Mr. Mills informs us that he is supplying large numbers of castings for oil and steam motors. There is a very

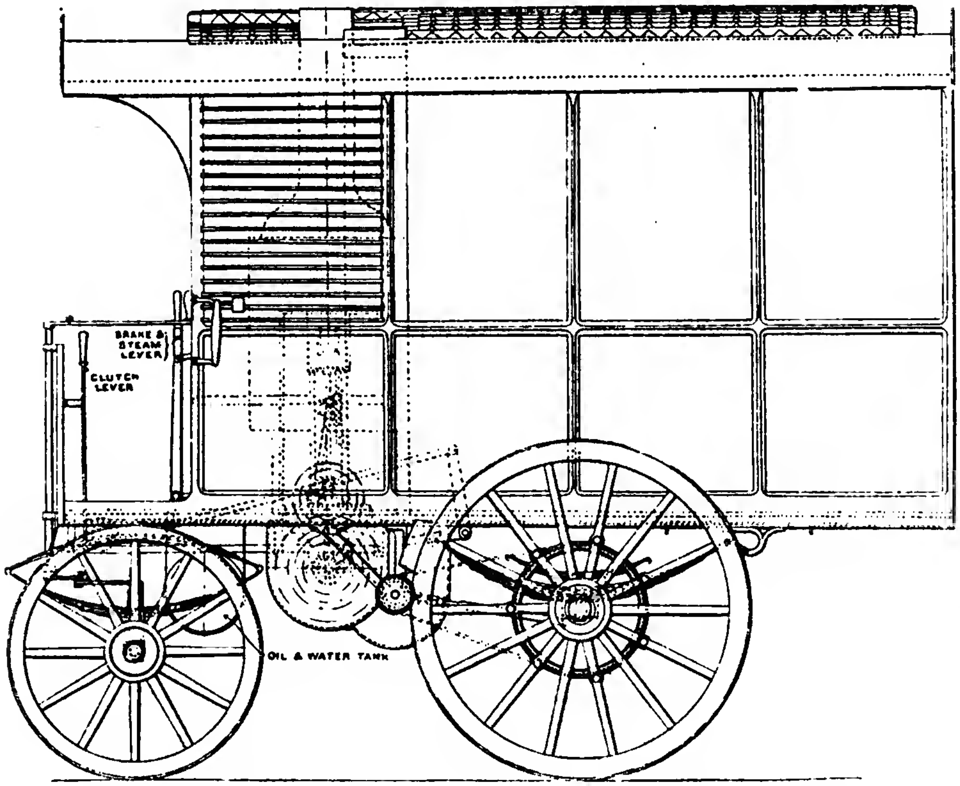

Fig. 4.—The Lancashire (Leyland) Steam Motor Company's Van (p. 418).

fine collection of yacht models, both steam and sail, and most of the launch builders are represented by full-sized vessels. The section relating to fishing is extremely interesting, especially to the pisciculturist.

Space forbids us to describe these things in detail, we can only say that the Yachting and Fisheries Exhibition at the Imperial Institute is one of the best shows now to be seen in London and well worth visiting.

THE ENGINEERS AND THE 8-HOURS DAY.

We have just entered upon one of those industrial wars with which we are so familiar in this country, and which periodically break out much to our own national loss, but very much to the advantage of the foreign manufacturer. The engineers demand an eight hours' day, and the employers refuse to concede it. As in all wars there is some ostensible ground for fighting, and in the present struggle this is the *casus belli* put before the public. As a matter of fact, both the engineers, or, more correctly, the Amalgamated Society of Engineers, and the employers, through their Federation, have long been spoiling for a fight, and war has at length been declared. To day the majority of our large engineering works are closed. Orders cannot be executed, and something like 75,000 men are idle. The men call the dispute a "lock-out," the masters say it is a "strike." It is not very material what it is called, but the principle involved is important. With the extension of the use of labour-saving machinery skilled hands are displaced, and boys and labourers can now do with the aid of a machine work which formerly required a skilled fitter. This replacement of manual skill and labour by automatic machine work is inevitable, and cannot possibly be resisted by any artificial means whatever. It is a noticeable and curious thing about this dispute that the boiler-makers are ostensibly not interested and are working. Those who are acquainted with the furious disputes between fitters—members of the Amalgamated Society of Engineers and boiler-makers—in the making of water-tube boilers, will have no difficulty in seeing why the boiler-makers are holding aloof. Both the employers and the engineers are well equipped for a fight, and any attempt at present on the part of anyone to arbitrate would be utterly useless and worse. We should deprecate any interference even from the Board of Trade. The probability is that in the large firms the strike or lockout of the engineers will have to be followed by a total stoppage. Moulders, boilermakers, pattern-makers, and other allied trades will be involved, as will platers, angle and other smiths, rivetters, &c., in the shipyards. It is, of course, very deplorable, but at the same time inevitable. So far no legislation and no law can, at any rate in this country, prevent these fights between capital and labour, and perhaps it is just as well that it should be so.

From experiments recently made on specimens of iron of different lengths, Mr. Henry Wilde, F.R.S., has found the magnetisation limit to be 422 lbs. per square inch, or 29·67 kilos. per square centimetre. In his communication to the Royal Society Mr. Wilde describes an experiment showing that the single-pole method of determining the magnetisation limit of magnetic substances compares favourably with the double-pole method, and that no higher degree of tractive force is to be expected from the latter than has been obtained from the former method.

THE I.E.S. ACCUMULATOR CELL.

ON the occasion of a recent visit to Woking, we made it our business to inspect the works and plant of the I. E. S. Accumulator Company. These are of a very extensive nature, and are

FIG. 1.

FIG. 2.

for the most part entirely new. Few people, except those concerned, know what a large number of operations and distinct trades are involved in the manufacture of a storage battery. The first essential is the manufacture of the glass cell; this is an industry which naturally is confined to Lancashire and Germany. We then come to the lead plates. Perhaps more ingenuity, time, and labour have been devoted to this item than to any other electrical detail. Ever since Faure and Planté showed how electricity could be, as it were, bottled up and carried about like any other kind of potential energy, inventors have unceasingly striven to increase the active surface, and to prevent the disintegrating action which takes place on rapid discharging. After innumerable trials the I. E. S. Company have succeeded in producing a cell which, for large extent of active surface, freedom from disintegration, and high capacity, will be found difficult to surpass. We say this with a full knowledge of the most recent tests conducted by independent observers. In order to obtain a large active surface, the lead grids were at first made as shown in Fig. 1.

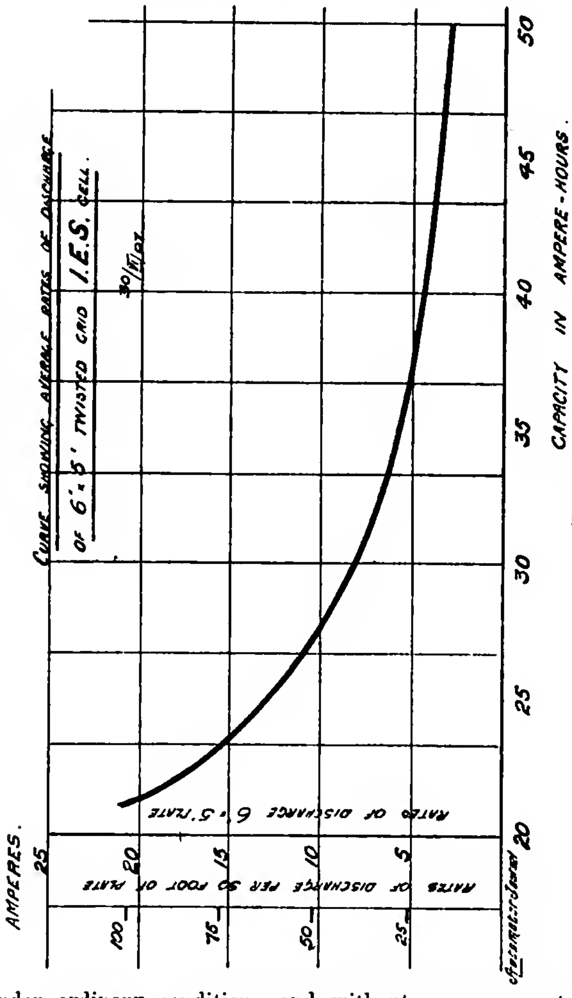

FIG. 3.

Under ordinary conditions, and without some support, this form of construction would be of little use, as surface would be gained at the sacrifice of rigidity and strength. In order to give the necessary support, each plate was enclosed in a perforated celluloid envelope; the celluloid, while giving support, is also an excellent insulator, and thus any accidental contact of adjoining plates prevents any short circuiting. The plate thus constructed was found to give excellent results, but it was further improved by making it in the form shown in Fig. 2. In this plate the lead takes the form of a number of lead wires, about 3 mm. diameter; these are corrugated and kept apart by strips of vulcanite; the plate is then pasted and enclosed in the perforated celluloid envelope.

Taking the "A 11" type as representing the cell most usually employed for traction purposes, each cell contains five positive and six negative plates, each plate being approximately 4¾ inches wide, 6¾ inches high, and ¼ inch thick. A rectangular jacket, about 5 inches wide, 7¼ inches high, and ⅜ inch deep, made out of perforated celluloid sheet about $\frac{1}{32}$ inch thick, surrounds each plate; and the plates are further kept apart by small narrow vertical strips of celluloid being inserted between the celluloid cases of adjacent plates. A plate is composed of 12 narrow vertical prongs of lead joined together at the top with a bar of lead, and at the bottom with a strip of celluloid. Thirteen thin strips of celluloid, each pierced at equal distances with holes corresponding with the 12 lead prongs, are strung on them, and these celluloid strips both serve to keep the lead prongs equally spaced all the way down, and to act as shelves to support the paste which is pressed in between them. The weight of the five positive plates is about 11½ lbs., and that of the six negatives 13 lbs.

From the results of numerous tests by electrical engineers of the most undoubted probity, these cells have extremely high rates of discharge, which make them admirably adapted for traction purposes. The following are the particulars relating to his cell:—

Number of plates, 11.
Weight, 55 lbs.
Charge ampères, 1—35.
Discharge „ 1—50.
Capacity in ampère hours at half list rate, 210.
„ „ „ full „ 150.
Size of box, 10½ × 9¾ × 7½.

As regards the weight of a battery of these cells in order to develop a given power for, say, 19 hours, the weight may be taken at ·67 ton per horse-power between 5 and 10 horse-power; but these cells would be quite capable of developing continuously a much higher power for a shorter period, or a normal rate of 5, 7, or 10 horse-power, with occasional increases to much higher powers, for nearly 19 hours. For instance, the 5 horse-power battery would give an average of 5 horse-power for nearly 19 hours, and up to 10 horse-power for short periods of a few minutes.

As regards the capacity of these cells the following curve will be of interest (*see* Fig. 3). It will be seen that at a rate of discharge of 5 ampères, the capacity in ampère hours is about 38 hours. If the discharge is increased to 15 ampères, or three times the rate, the capacity is about 22 ampère hours. It will be conceded that these results are extremely favourable for traction purposes. Among the latest orders received is one for a large battery for a large automotor barge for canal traffic in the Midlands. These cells were preferred as they stand rough usage so well—there being no possibility of short circuiting.

THE material known as "Pressspahn" is prepared from a specially selected wood fibre, treated with suitable material to enable it to be compressed through rollers into sheets of various thicknesses, ranging from 0·20 mm. to 4·00 mm. It is used for a variety of purposes, such as bookbinding, fancy articles, &c., and also for putting finish on cloth, velvet, or satin; but its chief employment is as an insulating material, capable of withstanding high temperatures, and in this direction it is stated to be invaluable to makers of electrical machinery and apparatus, being largely used in dynamo, alternator, and transformer construction, as well as for resistances. It is supplied by the International Trading Company, of 35, Queen Victoria Street, E.C.

The French Tax on Cycles, Motor-Cars, &c.—According to the latest French advices the Commission of the Chamber charged to examine the new octroi law voted by the Senate has adopted the recommendation intact. It thus would seem that the tax, in spite of the protests that have been made against it, will be doubled, viz., from 10 to 20 francs.

NOTES OF THE MONTH.

REFERRING to the article in our last number dealing with the show of obsolete fire-engines that the Queen was graciously pleased to inspect at Windsor recently, and in which the London County Council was the principal exhibitor, we communicated with the Chairman of the Fire Brigade Committee of the L.C.C. suggesting an interview between a member of our technical staff and the Chairman and Chief Officer of the Fire Brigade. We were rather desirous of ascertaining what was being done in the matter of automobilism by an "advanced" (*sic*) Municipality. Knowing that the Fire Brigade is hopelessly behind the age in every way, and that the L.C.C. has quite enough to contend with in its Works Department and other scandals, we were not at all surprised to receive the following letter:—

"Gentlemen,—In reply to your letter of the 5th instant, Colonel Rotton, the Chairman of the Fire Brigade Committee, desires me to say that he is so busy just now, and will be for some time to come, that he is unable to make an appointment with regard to the matter to which you allude.—I am, gentlemen, your obedient servant,

"C. J. STEWART, Clerk of the Council."

THE Laundry Machinery Exhibition will be held at the Agricultural Hall, Islington, from August 23rd to September 4th, when there will also be a show of motor-cars.

WRITING from Paris, "Free Lance" says in the *Irish Field*:—"In the morning I had a long ride in a motor-car in the Bois de Boulogne, and a very enjoyable and successful trip it was, the motor acting admirably, and the car being free from vibration and ill odours when in motion. It took four of us at a pace and a distance that no two horses in the world could have done without at least ruinous distress, but the motor-car never turned a bolt. Motor-cars and motor-cycles were everywhere; if we saw one we saw 50. They were under perfect control, and some looked quite handsome, it was a wonderful and rapid improvement over the little collection of cumbersome vehicles I saw hidden away in a dark corner of the first Paris cycle show."

WE had no idea the Russians had got so far ahead of the rest of the world in automobilism. According to the Hull *Eastern Morning News* an interesting trial was made a few days ago in Moscow with the motor-bicycle. Two hundred trained motorists mounted on their metal steeds were pitted against a body of Cossacks with picked horses. Their way led them over a clayey track, which recent rains had rendered most soft and slippery. The distance over which they had to ride was 200 versts, or about 120 miles. The Cossacks were allowed to change their mounts at different points on the road. The result of the experiment showed that the superiority of the horses on an unfavourable ground went without saying, while on a smooth hard track the balance was undeniably in favour of the wheelmen. But surely a mere 200 trained motorists would hardly enable the authorities to judge the capacity of motor-bicycles for practical work. Now if it had been 200,000 there might have been something in it.

IN their half-yearly report the Directors of the Burnley and District Tramways Company specially mention that the progress in construction of motor-cars is being carefully watched, and their use as auxiliaries to the tramway considered. This is significant from the fact that this Company is a successful one, and those controlling its affairs have always been ready to avail themselves of every new idea likely to be of permanent advantage to their shareholders and the inhabitants of their town.

AT a well-attended meeting recently of the National Cyclists' Union it was decided that no motor pacing be allowed in amateur races.

The following amusing description of an "incident" of the London streets is from the *Daily Telegraph*:—"Shortly after 7 o'clock a few nights back an exciting scene was witnessed in Holborn, when a terrific combat took place between an old-fashioned horse and a new fangled automobile velocipede, in which the latter was vanquished. On the automobile were a lady and gentleman, the former occupying the front seat. While they were passing the end of Fetter Lane a horse and van laden with chairs issued from the thoroughfare into Holborn, and then the fight began. Somehow or other the automobile, probably through a hitch in the steering apparatus, got among the horse's legs, and a smash promptly occurred. The lady leapt from her place and escaped without a scratch, but the gentleman fell on the roadway, and was within an ace of being stamped with the hoofs of the horse, which reared and plunged and kicked in a desperate manner. Fortunately, he rolled himself out of their reach and managed to regain his feet without much injury beyond a severe shaking. In the meanwhile the horse was prancing over the machine, which stood in danger of irretrievable damage. A number of men seized the animal's head and quieted it down, but it took them some time to convince it that the unwarranted attack on its legs by the horseless vehicle was an accident and not a premeditated insult. The automobile was carried away for repairs."

Two private members of the Paris Chamber of Deputies have given notice that they will bring forward a proposal to considerably increase the present customs duty on all cycles and cycle parts as well as automotors and parts imported into France. The proposal is to have a fixed duty on cycles of 600 francs per 100 kilo on the general tariff and 500 francs per 100 kilo on the minimum tariff. On automotors or detached parts it is proposed to put a tax of 200 francs on the ordinary tariff and 210 francs on the minimum tariff for automotors under 200 kilos; of 180 francs and 150 francs for automotors from 200 to 500 kilos; of 120 francs and 100 francs for automotors from 500 to 1,000 kilos, and of 60 francs and 50 francs on automotors over 1,000 kilos.

The undertaking of the Shoreditch Vestry in establishing combined electric lighting and dust destruction apparatus has proved a complete success, for within 10 days of the opening of the station the equivalent of 7,870 lamps (eight candle-power) has been ordered. The applications in hand already include one for charging electric-cab motors to the extent, it is said, of 200 horse-power. Under the new system, the destruction cells fed with parish refuse, are providing the whole of the steam required for the plant installed without the use of coal.

We hear that the original intention of utilising the Serpollet patents for tramway traction has been enlarged, and very shortly there is likely to be an extension in the scheme for utilising this special steam motor by the formation of a company to make and supply Serpollet carriages for use in England.

"No. 62," advertising in a contemporary, must either be extremely simple or must be looking for one of the proverbial fools, when he calmly advertises that he is prepared to sell 89 shares in the Great Horseless Carriage Company (Limited) for £250 the lot, or £3 per share for a less number. Probably "No. 62" is not aware that the nominal quotation of these shares in the open market is about 17*s.* 6*d.* per share, which no doubt is again open to "negotiation," as the market term it, which to those in the know has a very significant meaning.

"No. 38," immediately following, also seems to be dissatisfied with his investment in the London Motor Van and Wagon Company (Limited), as, although in his advertisement he holds out as an inducement that his shares in this Company are entitled to a preferential dividend of 6 per cent., as well as participating in surplus profit, he is fully prepared to accept £105 for 24 fully paid £5 shares, for an immediate sale.

An extensive fire occurred in Paris early last Monday morning in the Epinettes quarter, by which the workshops of the Co-operative Society of Carriage and Motor-Car Builders, situated in the Rue Pouchet, were completely destroyed. Besides this establishment, which belonged to one of the most important workers' associations of Paris, the conflagration also involved the adjacent Roger Motor Works, &c. The damage done is estimated at the sum of £20,000, and only part of the property destroyed is ensured. Two young workmen, who were arrested on account of their suspicious behaviour, declared first of all that they were both employed at Roger's Factory, but afterwards admitted that only one of them was a workman, the second having no employment. The genuine employé explained that he wished to give his comrade a ride on an autocar, and as the door of the works was open and the establishment was not watched at night, the two entered the building without difficulty. In looking for a lamp, however, they accidentally set the place on fire.

Recently a Mr. Guattari was gazetted bankrupt. Mr. Carlo Guattari, engineer to the New Motive Power Syndicate, is desirous that he should not be confused with his bankrupt namesake, and whilst confirming this, Mr. G. G. Belcher, the promoter of the N. M. P. Syndicate, we are glad to hear, states that the Syndicate not only obtained its capital, the shares being taken up by a large body of subscribers, but that it is proposed to invite the Press, in the course of two or three months, to a public demonstration of the advantages of the new motive power over any other hitherto introduced.

Replying to several enquiries, we understand that the action on behalf of some of the shareholders in the British Motor Syndicate is progressing as rapidly as the slowness of the law will permit, and that the case will in due course be set down for hearing.

The meetings of the Institute of British Carriage Manufacturers will be held at Southampton, at the Town Hall, on September 7th, 8th, and 9th.

We observe that *The Road* is indulging in self-congratulation upon the return of what it is pleased to call the "old coaching days." Then follows a good deal of gush about the "dear old coach," with its "four spanking tits." We have done some coaching in our time in Australia and New Zealand, but strictly as a traveller, and of all the experiences by land and water that we have had, a long coach drive over a dusty track with a southerly "buster" blowing is about the most unpleasant in the shape of travelling. Of course as a pastime coaching is to be encouraged, as it is a sensible one, in that it gives pleasure and employment to others, and, moreover, develops certain mental qualifications in the drivers of great use. Any sport which brings out nerve and pluck, coolness in danger, is to be commended, and so far we wish to encourage coaching, but as for sighing for the return of the "old coaching days" we emphatically do not.

It was hardly to be expected that the motor-car competition at the Crystal Palace could be an unqualified success under any circumstances as the industry is a new one. One would think, however, that a coaching competition could be arranged without the slightest difficulty, as coaches abound, and as for horses, do not our roads reek with their stench? According to *The Road* there has been a coaching competition at the Crystal Palace, but it was an awful frost. The public did not attend, and the person who got up the show acted as judge, with the result that envy, hatred, malice, and all uncharitableness prevailed among the coachees. So much for this attempt to revive the "good old coaching days."

DOINGS OF PUBLIC COMPANIES.

West's Patent Tyre-Setter Company (Limited) has been registered in Australia with a capital of £12,500 in £1 shares.

In a carefully-prepared summary of the half-year's new Companies which appears in the *Westminster Gazette*, out of a total of 77 millions sterling nominal capital, cycles are represented by 6½ millions, and Motor Companies by £550,000.

Referring to the Motor and Cycle Company of Ireland, recently launched under the auspices of Mr. Pennington, a correspondent in the *Dublin Herald* writes: "We were promised a very important addition to the few manufacturing industries in the possession of this old city of ours. Three months ago we were informed of the arrival at the North Wall of the tools, machinery, &c., and, of course, our hearts beat in high expectation at the prospect of seeing 2,000 "hands" employed in the gigantic concerns; but, alas! our hearts sank within us at the long delay, until about six weeks ago we noticed in the papers that a field of some 30 acres had been acquired in the vicinity of Ringsend, that a temporary steel structure was to be run up in the go-ahead American style while the permanent brick building was to be built outside it. I was looking at the field of the 30 acres a day or two ago, and could see neither a square yard of steel nor a brick on it." After the statements which appeared during the inception of the Company it behoves Mr. Pennington and the directors to see that no unnecessary delay arises in fulfilling the advantages then promised.

Great Horseless Carriage Company.

In regard to the resignation of the Earl of Winchilsea as chairman of the above Company, the following correspondence has been sent by the noble Earl for publication:—

To F. Crisp, Esq., Messrs. Ashurst, Morris, Crisp, and Co., 17, Throgmorton Avenue, E.C.

Dear Mr. Crisp,—I am very sorry to have to ask you to forward the enclosed letter, resigning my position as director of the Great Horseless Carriage Company, to the Board. I feel sure that it would be very desirable, if it could be arranged, that my brother, Stormont Finch Hatton, should take my place as chairman of the Board, and I think, if the Board agreed with me in wishing it, and he felt satisfied on looking into the matter that he could undertake it, that he would do so.

Will you, therefore, kindly place this letter, together with that containing my resignation, before the directors?—Yours very truly,

(Signed) Winchilsea.

57, Warwick Square, S.W.,
April 29th, 1897.

To the Board of Directors of the Great Horseless Carriage Company.

Gentlemen,—I believe you are aware that about three months ago, as the result of overwork, my health suddenly broke down, and Sir William Broadbent, who was summoned to Hastings to see me, ordered me at once to go to the Riviera. If I did not at that time send in my resignation it was partly because I was quite unable then and for many weeks afterwards to deal with matters of business in any way, and partly because, I indulged the reasonable hope that when I came back to England I should be able to resume my duties. But Sir William, who has now seen me again, is unfortunately of opinion that I am not in a fit state of health to undertake any responsible work. In fact, his orders are peremptory that I must at once and permanently very considerably reduce the number of my public duties, and refrain for a period of at least six months from work of any kind.

Under these circumstances, I have no option but to ask you to accept my resignation of the position I have the honour to hold as a director of the Company.—Yours very truly,

(Signed) Winchilsea.

Nuneham Park, Abingdon,
April 28th, 1897.

The Right Hon. Earl of Winchilsea, Nuneham Park, Abingdon.

My Lord,—Your letter, dated April 28th, received through Messrs. Ashurst, Morris, Crisp, and Co., was duly read at a Board meeting of this Company held on Friday last, and I am instructed to inform you that the directors exceedingly regret to receive your resignation as chairman and director of this Company, and they also deplore the cause that has necessitated you to do this.

The matter of a future chairman was discussed, and it was decided to defer same for the present.—I am, your Lordship's obedient servant.

(Signed) Chas. Osborn, Secretary.

40, Holborn Viaduct, London, E.C.,
May 17th, 1897.

The Electrical Power Storage Company (Limited).

Mr. J. Irving Courtenay presided at the meeting of this Company held last week, and said the free balance amounted to £4,485 5*s*., out of which the directors recommended a dividend of 5 per cent., carrying forward £242 0*s*. 2*d*. The buildings, plant, and tools generally were never in so good condition as they were to-day, and they had spent on their maintenance, renewal, and repair during the last year £2,048 15*s*. 2*d*., and in addition they had expended £526 11*s* 9*d*. on new plant. The number of plates sold during the year showed a marked advance on the sales of any previous year, thus indicating to some extent the importance of the goodwill of the Company's business. The new Faure-King accumulator was receiving the favourable consideration of a large number of buyers, and they had on hand, among numerous other orders, many important orders for these batteries for motor-car propulsion. This latter business, of which a good deal has been expected during the last two or three years, does not at present show much actual progress, but they would be interested to learn that the electrically-propelled dog-cart built by the Electric Construction Company, exhibited at the Crystal Palace, and which received the special commendation of the judges in *The Engineer* competition, was equipped with a Faure-King battery capable of running the vehicle 25 miles, a figure which represents working at twice the discharge rates given in their price list. This was a very hopeful departure, because the battery could be kept charged and properly maintained as new for a much less sum than it costs to fodder and attend to a horse.

After a few remarks, during which the chairman said the maintenance was paid out of revenue, the report was adopted and a dividend of 5 per cent. declared.

New Issues.

For the Month ending July 13th.

Tubes, American (Limited).—Capital £400,000 in £1 shares. Present issue 340,000 shares. Established to acquire the whole of the stock or share capital of the Ellwood Weldless Tube Company, of the city of Ellwood, Pennsylvania (who are entitled to Stiefel's United States patent), and of the American Weldless Steel Tube Company, of Toledo, Ohio. The assets of the Ellwood Weldless Tube Company include the whole of the stock or share capital of the Greenville Tube Company, of Greenville, Pennsylvania, which is thus brought within the combination. The prospectus states that the works are valued with freehold lands, railway sidings, stock, &c., at £166,741. The profits of the Ellwood Company are certified to have been at the rate of £41,550 per annum for 18 months to May 1st, and that the other concerns had been too recently established to provide any account of the Company's trading. Purchase price £289,675, of which the vendors take £144,837 in shares, and from the present issue about £40,000 will, it is estimated, be available for extensions and working capital.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles. We shall be pleased to reply with detailed particulars to inquiries through the "Answers to Correspondents" column. All communications should be addressed to the Editor. The only stipulation which we make is that where the inquiry involves a search of the records at Somerset House—as in the case of information on the subject of the holdings of shareholders—a postal order must be enclosed to cover the Government stamp of one shilling which is charged before a search is allowed to be made.]

	Capital.
Adelong Consolidated Gold Mines, Ld. (6 & 7, Queen St. Place, E.C.)	£125,000
Anderson Electrical Traction Syndicate, Ld.	5,000
Bagshawes, Ld. (159, Queen Victoria St., E.C.)	120,000
Beard's Cycle Fittings, Ld. (Frederick St., Wolverhampton)	20,000
Broughton Copper Co., Ld. (Manchester)	238,000
Brown Bros., Ld. (26, &c., Gt. Eastern St., E.)	250,000
Cash Cycle Co, Ld. (18, New Cannon St., Manchester)	5,000
Cycles and Automobiles Michaux, Ld.	100,000
New Defiance Cycle Co., Ld.	5,000
New Eadie Manufacturing Co., Ld. (Redditch)	160,000
Peerless Metal and Martino, Ld. (38, Princip St., Birmingham)	150,000
Pure Acetylene Gas & Carbide Co., Ld.	120,000
Safety Motor Syndicate, Ld. (49A, Lincoln's Inn Fields, W.C.)	1,500
Tubes (America), Ld.	400,000
Waterson Machine Fittings Co., Ld. (55, New St., Aston, Birmingham)	2,000
William Forbes, Ld. (224, Byres Rd., Glasgow)	5,000
Woodward Electrical Storage Battery Co., Ld.	60,000

LITERATURE RELATING TO AUTOMOBILISM.

[*N.B.—Publishers will please state price of books sent for Review.*]

"The Law of Motor-Cars, Hackney, and other Carriages." By G. A. BONNER, Esq., B.A., Barrister-at-Law. (London: Stevens and Sons (Limited), 1897.) Price 7*s.* 6*d.*

IT is a noteworthy sign of our civilisation that the legal liability of every person is now easily determined. Much ingenious artifice is occasionally displayed to evade the law, but ultimately the latter proves too strong, and the elastic phrase, "within the meaning of the Act," or that other, "the evident intention of the Legislature," is made to cover every case that can arise. Another noteworthy sign too is the anticipatory character of much modern legislation. We not only deal with facts as they are, but as they may be modified by fresh discovery. The law relating to motor-cars well illustrates both these tendencies. It is also not less indicative of the age we live in that no one can really plead ignorance of the law, because no sooner is a new law placed upon the statute book than there is almost simultaneously produced a large quantity of literature, technical and popular, which expounds and explains the subject so that those concerned can ascertain their legal liability with little cost or trouble. Although the use of automotors has been sanctioned for but little more than half a year, the legal literature relating to automotors is already pretty extensive, ranging from the handbook which explains the Act in a popular manner to the professional text-book written for lawyers. Of the latter character is the work before us, which forms an epitome of the whole law relating to vehicles. It is rather too generally assumed that the Legislature has treated automotor vehicles in an exceptional manner, but, as the author points out, the bulk of the law applicable to them is equally applicable to vehicles of other classes. The law relating to vehicles, including locomotives and other automotors, is contained in nearly sixty statutes, without including regulations made by local authority, police, &c. Surely this mass of legal enactments could well be consolidated and simplified. The first chapter discusses "Light Locomotives on Highways," and the author's explanatory comments on the various clauses are of considerable interest and value; thus, while smoke or *visible* vapour are forbidden, the Act is silent as to the emission of noxious or offensive fumes or vapours, and the conclusion seems to be that it is illegal to emit smoke unless accidentally, but a perfectly legitimate thing to emit an offensive vapour; but here again, as the author explains in another place, an offensive smell may constitute a nuisance. The great difference between a light locomotive and an ordinary locomotive on a highway in a legal sense is that the former must be under three tons in weight unladen, and not used for the purpose of drawing more than one vehicle (such vehicle, with its locomotive, not to exceed in weight, unladen, four tons), and so constructed that no smoke or visible vapour is emitted therefrom except from any temporary or accidental cause. The three conditions as to power (mechanical), weight, and non-emission of smoke, constitute a light locomotive. If any one be unfulfilled the machine ceases to be a light locomotive, and comes within the Acts regulating ordinary locomotives. A light locomotive is also a "carriage" within the meaning of any Act of Parliament.

Although by Sec. 4 of the Act a speed of 14 miles is permitted, it is as well to remind our readers that by the Regulations of the Local Government Board the outside speed of any light locomotive is 12 miles per hour. The speed permitted to the various classes of vehicles upon highways is embodied in the following table:—

Light Locomotives Unladen—

Under $1\frac{1}{2}$ tons. Speed not to exceed 12 miles per hour.
" 2 " but over $1\frac{1}{2}$. Speed not to exceed 8 miles per hour.
" 3 " " 2. Speed not to exceed 5 miles per hour.

When Drawing a Vehicle—

Under any circumstances not to exceed 6 miles per hour.

Locomotives (other than Light)—

Under any circumstances not to exceed 4 miles per hour. Passing through any city, town, or village, not to exceed 2 miles per hour.

The Petroleum Acts are then fully discussed. It is perhaps not generally known that, for the purpose of a light locomotive, the owner must either store oil in accordance with the provisions of the Petroleum Acts (*i.e.*, in pursuance of a licence), or he may keep it without a licence in pursuance of Regulations made by the Home Office. Chapter II discusses the Law relating to Hackney Carriages; under which category are included bicycles, tricycles, &c. This is succeeded by an ably written chapter on Negligence, which will repay careful reading. A similar remark applies to the chapter on Nuisances. The work covers the whole law relating to vehicles of all descriptions. It is one that, while undoubtedly destined to rank as a leading work on the law of vehicles, may yet be consulted with advantage by the ordinary layman. Mr. Bonner writes well and explicitly, and we congratulate him on producing the best work on the subject that has so far appeared.

INTERVIEWS WITH LEADING AUTOMOTOR ENGINEERS.

Mr. Anthony G. New and Mr. E. Mann.

nected with horseless traction. His opinions, therefore, will be read with interest by the automotor community.

Mr. New is also a director of the I.E.S. and other electrical companies, and has the proud distinction of being among the first pioneers of the motor-car movement to be fined for running a motor vehicle without a licence.

All technical matters come before Mr. New, who usually is to be found at Woking. The commercial department is managed by Mr. E. Mann, who was born in 1855 and was educated at Paris and Rugby. He has had a large commercial training, having filled various important commercial positions in the Brazils, West Africa, &c., with conspicuous success. Returning to England in 1889 he "went in" for electrical engineering—that is in its commercial aspects, and several enterprises owe not a little of their success to his administrative ability. On the formation of the firm of New and Mayne he became the business director, a post he still holds, and so far the association of Mr. New and Mr. Mann has been satisfactory to themselves and their clients.

Ever since the Locomotives on Highways Act was projected the firm of New and Mayne have been carefully studying the possibilities of horseless traction. Wisely, they have not attempted to proceed without seeing how far purely theoretical design would have to be modified by practical experience, and

oking for a long time past. in that town, "something a very small second-class ark: "Oh, it's only one of New and Mayne's experiments."

Messrs. New and Mayne's London offices are situated in Bridge Street, Westminster, London, opposite the House of Commons. From the windows of the first floor is obtained

of the identi- with - pro- other The works and factories of the firm are, however, at Woking, and they have branches in the principal provincial cities. Central station work is their special industry, and in this connection Woking furnishes a good example of successful lighting. Woking depends upon two great industries—the creation and disposal of motors. The one is the final disposal in the earth of human motors from which all the energy has been exhausted, and the other is the production of mechanical motors which derive their energy, whether in the form of coal or petroleum, also from the earth. Woking is not, however, proud as might be thought, but is merely, in a modest way, a very up-to-date town. It will not only literally "undertake" one according to the most approved methods, but it will also undertake to show you the latest thing in automobilism. Mr. New, who resides in Woking among his workpeople, has not, we believe, any connection with the "other" industry, but is very much concerned with the decidedly more vital question of automobilism. Unlike so many people who, because they own a gee-gee or can drive a trap, think themselves competent to express an opinion—usually of no value—upon horseless traction, Mr. New has taken up the subject in a purely scientific manner, with of course an intention of obtaining commercial advantage.

Knowing what is being at present done in the automotor industry, and knowing what Messrs. New and Mayne were doing, we solicited permission to subject the members of the firm to a species of inquisition. Not only did we visit Woking

Mr. Anthony G. New.

and saw what work was being carried on, but a representative of the AUTOMOTOR lay in wait at the London offices of the firm and seized his victims as they were emerging from a board meeting, and refused to release them until they had answered the following questions:—

"About how many hands are employed by you in the actual manufacture of motors, storage cells, and other appliances strictly intended for motor-cars?"

"We are at the present time employing about 80 hands in the manufacture of motors, electric accumulators, and other appliances for motor-cars."

"What is the average amount of weekly wages paid these hands?"

"We are paying £140 per week in wages for motor-car work alone."

"Have you completed any orders for automotors?"

"We have not yet completed any orders."

"Have you any orders on hand?"

"We have orders on hand and have had to refuse many, as we could not guarantee delivery soon enough for the requirements of the present season. There will be no difficulty, however, in picking up these orders again for next season."

"You have spent a good deal of money in experimenting, have you not?"

"We have spent large sums of money in experimenting?"

"Do you, as the result of your costly experiments, think that the automotor industry is worth following up? For instance, do you think that it would pay firms of established repute to go into the manufacture of automotor cars?"

"We are absolutely of the opinion that the automotor industry has come to stay, and we think it will be not only to the interest of established firms of repute to go into the busi necessary for them to do s have spent a good deal of out commercially successfu

"What special points a differentiate the applicatio say, road locomotives, la &c.?"

"There is a difference b horseless vehicles and for l propulsion, inasmuch as in necessary to provide mean to be done by suspension s much as possible from the

"At present a horse-dra

to persons with etence to mechanical knowledge, would no cle require a skilled driver?"

"We have no able to turn out automotor vehicles which any mechanical knowledge whatever in th at any man can pick up in a week."

"What would be the weekly wage of a competent driver of an automotor?"

"There is no reason why competent drivers for horseless vehicles should not be obtained at the same rates as are paid to ordinary carmen, cab drivers, &c."

"Suppose I want a motor-car to ; say, for a draper purpose for which it is intended. We deprecate the use of light oil at all, on account of its volatile and inflammable properties and the consequent danger of explosions, and also as light oils, such as benzoline or petrol, cost considerably more than petroleum and are not readily obtainable, on account of the restriction against storage of same and the small quantities in which they are allowed to be sold retail, besides which the power obtainable is less in a given quantity. Heavy oil or petroleum for use, either as fuel for an oil-engine or as fuel for the boiler of the steam system, should be the most useful fuel in conjunction with the new industry. The new high-speed oil-engines, by reason of their light weight and the small space they occupy, are very well adapted for road traction, but as, to work economically, it is advisable to have a constant load, and as also there are inconveniences attended with the stopping of a carriage driven by an oil-motor without stopping the motor, we suggest that in conjunction with the oil-motor there should be used a small dynamo and a light battery of electric accumulators. The accumulators when charged serve to drive the dynamo as a motor to start the oil-engine, and when its proper speed is attained the motor overcomes the resistance of the batteries and puts a small current into them while the engine is running. If the full power of the motor is being used, say, for going up a hill, no current would be going into the batteries, but running down hill, or when the carriage is stationary, the available power would be charging the accumulators ready for when they were wanted, either for starting or assisting the motor again, or for lighting the lamps of the vehicle. The steam system mentioned above using petroleum for fuel for the boiler can be made absolutely automatic, so that the steam pressure in the boiler regulates not only the amount of fuel used, but also the feed of water to the boiler, and of course in a steam system the varying power required is provided for by more or less steam being used, as the case may be. With regard to the electric propulsion of vehicles, there is a large field for this, using electric motor and accumulators, but these should be used only in paved streets, or where the roads are thoroughly well macadamized and the gradients small; and as accumulators require careful attention to keep them in good condition, we only recommend their use where there are a number of vehicles used by one firm, as the wages of a man capable of looking after a set of accumulators used for traction would be excessive, whereas the same man would look after 20 or 30 sets, and his wages distributed over these would be a small item in the total maintenance."

"Suppose I own an electric motor-car for trade purposes, say, as before a grocer; I occupy large premises in, say, Oxford Street or Whitechapel. I supply customers within a radius of four miles. What facilities should I have for re-charging?"

"A tradesman owning an electric motor-car for trade purposes would have to consider the question of where he could get his accumulators re-charged. In those parts of London, for instance, covered by companies who supply direct current, he would have no difficulty in charging his accumulators in his own yard, and by having a duplicate set of accumulators, so that one set could be on charge while the others were in use, he could arrange very reasonable terms with the Supply Company for charging in the day time. In those areas which are supplied by the Alternating Current Companies, there would be the difficulty of having to send his accumulators to the supply station to be charged. This, of course, applies to other large towns which have only the alternating current available. They have direct current in use at their generating stations for exciting their alternators but do not transmit direct current to their customers, therefore, anyone having batteries to charge must send them to the station."

"What is the least cost of E. energy per unit = 1 kilowatt?"

"With regard to cost of supplying energy for charging the accumulators for motor-car work, we understand that arrangements have been made with some of the large Supply Companies in London to supply current to the London Electrical Cab Company for their vehicles at rates which average out at not exceeding $1\frac{1}{2}d.$ per unit."

"Can you compare the relative weight and efficiencies of, say, a two-horse van carrying $1\frac{1}{2}$ tons, and an electric motor-van carrying the same weight? (N.B.—In all cases the weight of the horses is to be added to the weight of the van.)"

"Although it is an extremely difficult matter to give a general idea of the comparative weights and efficiencies of automatically-propelled vehicles of different kinds, our opinion is that considering a van for carrying $1\frac{1}{2}$ tons of goods, such as is now drawn by two horses, the weight of the van itself if motor driven would be about 30 per cent. heavier than the horse-drawn one, and the weight of machinery would be approximately as follows:—Steam or oil, 5 cwt.; oil and electric combined, 10 cwt.; and electric (accumulator for short journeys), 20 cwt. We do not consider that the weight of the horses should be considered in this comparison."

"You have no doubt seen the statement of *The Engineer* to the effect that at present there is no 'really satisfactory motor.' Is there in your opinion a 'really satisfactory' mangle, sewing machine, battleship, lifeboat; or do you know of anything, any machine, institution, or anything human at all which *is* 'really satisfactory'; because, if you do, I don't, and our readers, like me, simply pine after anything 'really satisfactory'?"

"We do not think that the statement made by *The Engineer* 'that there is at present no really satisfactory motor for horseless vehicle traction' is fair. It is very difficult to say what is a really satisfactory anything. Constant improvements are being made in steam-engines, sewing machines, laundry machinery, in the management of institutions, and, in fact, in everything you can think of, and if the public is to wait to use an article until it is so satisfactory that no improvements can be made, all industries would soon be at a standstill."

"Having so far disposed of the automotor car, I would like you to tell me something about another branch of automobilism in which I believe you are interested—I refer to your rudder-motor. So far, I have seen this applied with advantage to small river boats. Can it be used for canal propulsion? Say, for instance, I have a lighter that will lift 60 tons D.W., can I employ your rudder-motor?"

"Our rudder-motor has so far only been used for propelling small craft, the largest being two horse-power machines, and these are suitable for propelling ships' pinnaces capable of holding about 20 people, and will propel them from five to six miles an hour, but there is no reason why they should not be used of larger size for purposes of canal or river work. Lightermen, who practically control the river and canal transport, would save a large sum in wages if their barges were electrically propelled by means of the rudder-motor and batteries, as they would dispense with the necessity for tugs, which means not only the outlay for the tug, but also the constant expense of engine-room hands."

"What do you think is the future of canal traffic? Will horses be superseded by automotors?"

"There is no doubt that the time is coming very near when the use of horses for canal traffic will be abandoned and mechanically-propelled canal boats will supersede them."

"One more question, and this infliction ceases. Is there an automotor industry in this country? *The Engineer* says there is not, and our readers want to know. We also want to know, because we can't very well continue to enlighten the public about an industry which does not exist. I myself am under the impression that there is a large number of firms, including your own, who manufacture motors as a relaxation, or from a philanthropic desire to keep the hands on, or even as earnest seekers after engineering truth?"

"That there is an automotor industry in this country is undoubted. Large sums of money have been spent in acquiring patents. A great deal of experimental work has been done and costly machinery put down for the production of motor vehicles. There has, however, not been time since the law which prevented the use of motor-cars in the United Kingdom was repealed to show anything substantial in the way of results. Several well-known and old-established firms are working on steam carriages; others on oil motor vehicles. Quite a number again are working on electrically-propelled vehicles, and we expect shortly to see 40 or 50 electric cabs running in London."

"I need hardly say that our readers will be deeply interested in your replies. This interview will do much to restore public confidence in the future of the automotor vehicle."

CORRESPONDENCE.

_ *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

_ *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

A MOTOR-CAR DESIGN.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I have designed a steam motor-cycle, which I purpose constructing for experimental purposes. I should esteem it a favour if you will give me your opinion as to the relative proportions I have decided on for the engine and boiler. The cycle has three wheels, and is to carry two persons, to attain a speed of 12 miles per hour, and to use petroleum as fuel; the weight, with fuel and water, approximately 2½ to 3 cwt.

(1) The engine I propose to have 2 horse-power; cylinders, 2¼ inches bore, by 2¼ inches stroke; steam pressure, 150 lbs.; revolutions, 500 per minute. Is this engine powerful enough?

(2) The boiler I propose to be of the flash type, the tubes to be ⅜ inch bore by ⅞ inch outside diameter. Is this proportion of bore to outside diameter suitable for this class of boiler?

(3) The boiler has been designed to give a total heating surface of 5 square feet, and a grate area of ¾ square foot. Are these sufficient for the duty required?

If you consider any of the points of the design faulty, I shall be much obliged if you would suggest where they should be altered.—Yours faithfully, R. F.

[(1) The power, about 4·8 B.H.P., would be ample. (2) To obtain the full advantage of the principle of the flashing steam boiler your tubes should be very much thicker. (3) Heating surface is too small; we suggest at least 2 square feet per I.H.P. We could hardly criticise the design without seeing the plans. In the Automotor Diary you will see a list of firms who supply motor-car accessories, or see the letter in this number from the London Motor-Car Works.—Ed.]

"HORSELESS CARRIAGES"—SOMETHING DIFFERENT WANTED.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Pending the production of an engine suitable for road locomotion (is it to be the steam turbine?), a few remarks as to the general form of self-propelled vehicles may not be out of place. The designer of such a vehicle appears to imagine that all that he has to do is to take an ordinary carriage, remove the horse and shafts, and attach his more or less impracticable engine to the rear wheels. The result, in almost every case so far, has been a vehicle of grotesque appearance, and this not only from the absence of the accustomed horse, but from its obvious unsuitableness to the new conditions. In a horse-drawn carriage the small steering wheels are, to a certain extent, lifted over obstructions by the horse, and the jolting due to their small size moderated somewhat, but when the force is applied from behind, and the steering wheels driven dead against every obstruction, the effect is very different. It seems to me, therefore, that our plan should be to make the steering wheels *large*, as in the American buggy, or the more familiar coal-cart, designs adapted respectively for rough roads and heavy weights. It is not of much use to have large driving wheels if the steering wheels are small, and for the new conditions these latter should be enlarged even if this involves raising that portion of the floor of the vehicle that is over them. Another point:—Under the new and horseless conditions, should the steering wheels be leading or trailing, in front or in rear? Here, again, we must not be prejudiced by custom, but should consider whether the driving wheels should *push* or *pull* the steerers. My own opinion is that they should *pull*, as they do in Mr. Thornycroft's steam van, the chief reason, perhaps, being that the more lightly-weighted steering wheels, by *following* the drivers, will find the way prepared for them, so to speak. In many cases it might be advantageous to place the driver's seat over the steering wheels at the back, but where this cannot be done the steering may be readily effected from the front by means of rods. For very heavy traffic it would probably be advantageous to have *two* pairs of driving wheels in front coupled together as in a locomotive, the tendency to sink in soft ground being diminished by distribution of the weight. This well-known principle does not seem so far to have been applied to road traffic at all.—I am, &c., A. J. Allen.

London Institution, Finsbury Circus, E.C., *June 27th.*

[We hope to discuss the technical point raised by our correspondent in a future number. In the meantime we may say that in our opinion designers will not greatly err in imitating advanced locomotive practice.—Ed.]

THE ARNOLD CAR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—In looking through the June number of Automotor, on p. 350, you say: "The next motor (Fig. 15, p. 356) is entered by Mr. Cornell. Owing to our inability to obtain drawings, or even much information concerning it, we must be content with the briefest description. We understand that light oil is employed in an ordinary Otto cycle engine having electric spark ignition. Neither this motor nor its performance call for any special notice."

As the above is likely to convey a false impression, may I ask you, in fairness, to say that this little carriage was running at Margate a year ago for three weeks? I then drove it (with my wife) from Margate to Southampton and back in August last. It was then driven in Southampton in September. I also drove it from Tonbridge to London, November 13th, and thence to Brighton on the memorable 14th, arriving at Hotel Métropole at 6 o'clock.

I have driven the little Arnold "Sociable" nearly 3,000 miles, and have been delayed only once, through exhaust-valve choking; that is now corrected by substituting non-corrosive metal. With regard to drawings, I have them now before me, and also a letter to the following effect:—

"*The Engineer*,
"33, Norfolk Street, Strand,
"June 17, 1897.

"Dear Sir,—In reply to your letter of yesterday's date I shall have much pleasure in returning your drawings, and also your entrance fee of £1, to which you are entitled as actually competing.

"I need not tell you how much I regret the circumstances which left you alone in your class.—Yours faithfully,
"S. White."

I was at *The Engineer* competition, quite prepared to start on the journey to Birmingham, having driven the car over the same ground three weeks previously, and could have done the distance comfortably in 32, instead of the 52 hours' time allowed.

Since then Mr. Coles (its present owner) has driven it in London and other places continuously with perfect success.

I should have been too pleased to have furnished any information, but it has already been well described in *English*

Mechanic, *Scientific American*, &c., of which I enclose reprints. It is surprising how the motor-car proper has been misrepresented. As it has taken 60 years to evolutionise the perambulator, why should we look for showers of motor-cars?—Yours faithfully,
A. Cornell.
Tonbridge.

[We willingly publish the above letter, but do not see our way to modify the statement complained of as we are still without any technical knowledge of the Arnold Car. We gave a photograph of it in our last number, this, however, merely conveys an impression of its external appearance. The reprints mentioned do not furnish the information we want. If our correspondent will supply us with working drawings, official tests, &c., we shall be glad to publish them. Exact technical information is what we desire to supply our readers with.—Ed.]

WANTED—A MOTOR-OF-ALL-WORK.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I intend to take up an agency for motor-cars for this district as I am in the same line myself here on a small scale. I think for all that has been said against them there is some in the market that would do—but I want your advice as to what you think is the best oil-motor in the market. What I want is a motor-car to carry five cwt. and to carry two persons beside, and the oil-engine to be used when at home for driving purposes, such as a small dynamo for electric lighting. By inserting answer in your next issue I will feel obliged. Do you consider the Pennington motor up to date? I see they are making a lot of it in Dublin.—Yours respectfully,
Motor.

[We could not undertake to advise as to the "best" oil-motor. Your better plan would be to state your requirements to a consulting engineer who makes motor-cars a speciality (*see* the Automotor Diary). We do not think it would be feasible to employ the oil-motor to drive a dynamo in the way suggested, as a heavy fly-wheel would be necessary, besides the base of a van would hardly make a sufficiently rigid foundation. You would find the light so produced very unsteady. At the same time it would be quite possible to design a motor-car so that when idle the motor could be used to drive those machines in which a regular turning moment is not important. The Pennington motor is unquestionably "up to date" in the sense that it develops a relatively large power on a small weight of engine. It is successfully employed in driving very light vehicles, but we have not heard of its application to ordinary tradesmen's vans.—Ed.]

PARTS FOR AUTOMOTORS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—We should like to mention that we have laid down a plant of the highest order for the especial purpose of manufacturing all the ball-bearings, axles, hubs, and controlling gears for motor-cars, and should be pleased to receive correspondence relating to this work.—Yours faithfully,
The London Motor-Car Works Co. (Ltd.).
Albert Mills, Beavor Lane,
Hammersmith, London, W.

[The above letter no doubt is in reply to "Pateutee's" letter in our June issue.—Ed.]

THE PETROLEUM CAR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—The Select Committee of the House of Commons meets to-day at 3 p.m. to consider further proceedings in respect of the dangers of petroleum and lamps. The fiasco of *The Engineer* Exhibition and of the automotor-car in general, as I read in your last issue, leads me to suggest the possibility of developing the petroleum car without danger and odour—through the medium of your publication. In this matter of safety in the use of petroleum as fuel, and paraffin as an illuminant, my researches encourage me to say that such is absolutely possible.—Yours faithfully,
C. E. Parker Rhodes.
July 8th.

[We shall be glad to have particulars of our correspondent's plans. We quite agree that it is possible to eliminate all danger from the use of petroleum.—Ed.]

THE LATE MR. LAVINGTON E. FLETCHER.

We regret to record the decease of one of the early pioneers of the automotor in Great Britain, and who in his later years was one of the most advanced and scientific engineers of the day. Mr. Fletcher was best known to the present generation as the engineer-in-chief of the Manchester Steam Users' Association. Indeed, the extraordinarily high position and authority that this body — a private corporation — occupies and wields is due almost entirely to the engineering skill of Mr. Fletcher. For anyone to question the dicta or practice of the Manchester Steam Users' Association is to say that the person is a greater authority than Mr. Fletcher, or that he has much to learn. Mr. Fletcher was perhaps the greatest authority in his time on boiler construction and management, and Lancashire, especially, owes much to him. Mr. Fletcher was born in 1821, so he had lived beyond the usual three score and ten, and to few of us is it given to lead a life more full of usefulness to our fellow men than that led by Mr. Fletcher. He commenced life as a railway engineer, but obtained a successful practice as a consulting engineer in other industries, notably paper and biscuit making. He at this time, *circa* 1842, investigated the problems of horseless traction, and designed and had built in Reading, at a cost of between £300 and £400, a road locomotive, weighing complete with fuel and water, about 18 cwt., maintaining a speed of 12 to 20 miles an hour, and taking 8 to 10 passengers up a hill of 1 in 12 at 12 miles an hour, working pressure 360 lbs. per square inch. This information is furnished by Mr. J. Spencer, of Manchester, who steered the carriage for a long period, and assisted as an engineer apprentice in its construction. From 1846 to 1850 he was engaged under Mr. J. K. Brunel, C.E., chief engineer to the South Wales Railway.

In January, 1861, Mr. Fletcher was appointed chief engineer to the Association for the Prevention of Steam Boiler Explosions, now known as the Manchester Steam Users' Association. With this organisation he was engaged up till the date of his death, so that he had been connected with it for the long period of 36 years. It is almost impossible to over-estimate, says *Engineering*, the great influence he, as the chief organiser, exerted on legislation relating to steam boilers and machinery. At the time of his death he was engaged in furthering the Bill introduced into the House of Commons by Sir William Houldsworth, which seeks to secure the periodical inspection and certification of practically every steam boiler in the kingdom. Mr. Fletcher was a member of the Institution of Civil Engineers and of the Institution of Mechanical Engineers. Before the latter Institution he read, in May, 1876, a valuable paper on "The Lancashire Boiler: Its Construction, Equipment, and Setting."

Motor-Car Exhibition at Harrogate.—On Saturday last the Yorkshire Motor-Car Company, of Bradford, opened, at the Spa, Harrogate, a seven days' exhibition of motor-cars and motettes, which proved of considerable interest. The horseless carriages were shown under the direction of Mr. J. E. Tuke and an assistant, and trial runs are being made each afternoon and evening.

NAUTICAL AUTOMOBILISM.

The Hydraulic Steam Lifeboat "Queen."

IN this jubilee year when we are all metaphorically patting each other on the back and congratulating ourselves on our wonderful "progress" it probably occurs to very few to consider how very slow that progress is. Take, for instance, lifeboats. Practical steam navigation is about 70 years old, and the first steam lifeboat was built seven years ago. Some very hard things have been said about the Royal National Lifeboat Institution recently, and one of the most damaging indictments against it is that it has done absolutely nothing to solve the problem of small craft automobilism but has clung to the archaic system of rowing, and even in its adoption of steam the system of propulsion selected is the least efficient known. The reason for the preference of the hydraulic system of propulsion to ordinary screw propulsion is that in the former there are no external propellers to be fouled or damaged by wreckage. This advantage is, however, very far fetched. In the days of the old wooden sailing ship, masts, spars, &c., were of wood. Rigging was of rope, and hence when the vessel was stranded she quickly broke up and became a mass of floating wreckage. Nowadays the majority of vessels are of iron or steel as are their masts, yards, &c., and even when the latter are of wood the rigging is of iron wire and chain, and when these vessels get ashore they rarely break up but have to be blown to pieces by explosives, and if their masts do carry away the amount of metal attached makes the wreckage sink alongside and hence the risk to vessels of fouling their propeller when going alongside is extremely remote. Indeed, small screw tugs and trawlers habitually are on the look out for wrecks with an eye to possible salvage, and it is very rarely that they receive damage to their propellers either from wreckage or fishing nets. There is thus then no valid reason for the retention of such an inefficient system of propulsion as the hydraulic system. On the other hand, this system is particularly liable to break down from causes which would be absolutely harmless to a screw propeller. Thus small pieces of wood which would be brushed aside by a screw are drawn into the hydraulic turbine and break the impeller. Several instances of this have occurred with these hydraulic lifeboats. Moreover, if there is one class of operation in which fouling would be attended with the gravest consequences it is in submarine mining, but neither the War Office nor Admiralty will entertain the idea of hydraulic propulsion. In fact, very high authority has condemned it for lifeboats. Notwithstanding the many objections to the hydraulic system, the Royal National Lifeboat Institution adheres to it—why, it would be difficult to say—and hence gives occasion for critics of the Institution to complain that the money of the charitable is not laid out in the best and most efficient manner.

FIG. 1.—THORNYCROFT'S HYDRAULIC STEAM LIFEBOAT (Longitudinal Section).

FIG. 2.—THORNYCROFT'S HYDRAULIC STEAM LIFEBOAT (Deck Plan).

The vessel we are about to describe and illustrate is named the "Queen." She has been built by the eminent firm of Messrs. Thornycroft and Co., of Chiswick, whose name is sufficient guarantee to the public that materials and workmanship are of the highest possible quality. Messrs. Thornycroft are, however, not responsible for the design and system of propulsion, this emanating from the Royal National Lifeboat Institution. In view of our remarks this point must be carefully borne in mind. Indeed, we may go so far as to say that Messrs. Thornycroft favour the turbine propeller system of propulsion—a very different thing to the hydraulic system, and which they successfully designed and applied to a torpedo-boat some years ago.

The "Queen" is 55 feet long, beam at water-line, 13 feet 6 inches; beam on deck, 16 feet; depth moulded, 5 feet 6 inches. Load draught with all stores, 4 tons of coal, water tanks full, and 39 passengers and crew, 3 feet 3 inches, at which draught the displacement is 31 tons. The hull and framing are of the best mild steel. In the arrangement of the plating and framing everything has been done to obtain the greatest longitudinal strength. In view of the short steep seas through which the "Queen" will have to steam this is very necessary. Thus the frames are connected by diagonal braces, and the butts of the steel plating are double, and in some places treble riveted, even the longitudinal seams being double riveted. The hull is further tied and strengthened by numerous transverse bulkheads. The system of construction is, indeed, in some respects superior to that followed in the first-class torpedo catchers. The subdivision is very perfect, there being 18 separate compartments. Above the water-line the hull is sponsoned out increasing the beam on deck to 16 feet, including a belt of American elm carried right round, and which is 6 inches in depth. The general design and arrangement will be seen by the accompanying drawings. The upper extremities of the vessel are plated over so as to form turtle backs. Midships the deck is raised about a foot leaving a gangway at the sides, this gives good consist of a pair of compound surface condensing engines, having cylinders $8\frac{1}{2}$ inches by 14 inches diameter, by 12 inches stroke. As will be seen, the cylinders are placed on their sides, the L.P. below and inclined to each other; the piston rods are coupled direct to the pump spindle by connecting rods. Ordinary link reversing and valve gear is fitted. The weight of the impeller and any downward thrust is supported by a thrust bearing on the upper end of the pump spindle, to which is also attached a pair of feed and bilge pumps. The machinery is characterised by simplicity and strength; there is nothing complicated. All bearing surfaces are large and great attention has been paid to the lubrication. There is a somewhat lavish use made of gun-metal, the pump-chamber and eduction pipes being entirely of this metal. The discharge valves are actuated by rods and bevel gearing, which terminate in two hand-wheels placed outside and abaft the engine-room after bulkhead in the cockpit, immediately facing the coxswain, who thus can manipulate them and steer at the same time.

Steam is supplied from a Thornycroft water-tube boiler placed in a separate stokehole, and which can be made air and water tight. The boiler has $11\frac{1}{2}$ square feet of grate area, and 610 square feet of heating surface. The normal steam pressure is 140 lbs. per square inch. Under ordinary conditions natural draught will be used, but when steaming in heavy weather or when towing forced draught will be employed, a small steam fan in

FIG. 3.—THORNYCROFT'S HYDRAULIC STEAM LIFEBOAT (Hold Plan).

head room in the boiler and engine rooms. Abaft the engine room is a large cockpit, the deck of which being above the mean water-line, any water which may be shipped easily runs out through the self-freeing valves. The end compartments form buoyancy chambers. In the matters of stability and reserve buoyancy the "Queen" is all that can be desired and is practically unsinkable and uncapsizable.

The hydraulic system of propulsion may not be known to all our readers, and a few words describing it will not be out of place. About the centre of the boat, and close to the bottom, is a centrifugal pump, 2 feet 6 inches in diameter, placed on its side. An inlet scoop in the bottom of the boat is formed by recessing the hull, as shown in Fig. 1, so as to permit a free flow of water to the pump. To the pump casing on each side (*see* Fig. 3) are two eduction pipes fitted with valves and leading to the side of the vessel. By changing the direction of the discharge by means of these valves the water pumped in is discharged either ahead or astern on each side, and it is the reaction which forms the propulsive energy. Thus, to go ahead the water is discharged aft, and *vice versâ*. Similarly, by discharging aft on one side and discharging forward on the other the boat is turned. The ease of manipulation is, perhaps, the only really good feature of the hydraulic system. It is not necessary to reverse the engine, which always runs in one direction, and the valves are under the control of the coxswain. As will be seen, the spindle of pump is inclined so as to rake aft; this is for the purpose of permitting a more uninterrupted flow of water to the impeller. The engines driving this pump the engine-room easily maintaining 3 inches of water pressure. The fuel will be coal, there being a bunker capacity of four tons, but Holden's Liquid Fuel Burner has also been fitted. Believers as we are in petroleum, we nevertheless question the advisability of using liquid fuel for lifeboats. The reason for its employment is, we understand, the difficulty of firing with coal in a heavy seaway.

Feed water and oil are carried in tanks. The condenser is of brass and of the ordinary torpedo boat type, and is worked by air and circulating pumps, driven off the L.P. tail piston rod. There is also a steam motor driving a small warping capstan on the forecastle head.

In every respect, save that of the system of propulsion, the "Queen" is a beautiful vessel. The workmanship is of the best possible description, and all the details have been most carefully and ably worked out. Indeed, we cannot but ask, Is it really necessary to adopt such high-class and costly workmanship, when the same end could be attained by a cheaper system of construction?

The cost of this vessel cannot be less than £5,000, or £170 per ton of displacement, or, assuming her gross tonnage to be 21 tons, her cost is £250 per ton, a price absolutely unprecedented in all our experience even of palatial yachts for millionaires.

The "Queen" has not yet been under steam, but as she is an almost exact duplicate in every respect of the "President Van Heel," a lifeboat built by Messrs. Thornycroft for the Dutch Government, the results obtained in the latter will be approximately those that may be anticipated for the former. With a steam pressure of 140 lbs. the engines made 450 revs. per minute, giving a mean speed of 9·3 knots with 250 I.H.P., this gives the Admiralty coefficient of performance as being 32. In boats of this size it should be not less than 100, or in other words the efficiency of the steam hydraulic lifeboat is only about one-third of what it should be.

A POEM.

THE motor-car has a beauty of its own, "indefinite, unspeakable, and distinctly precious," as Bunthorne would say. That prosaic and practical paper, the *Hardware Trade Journal*, has recognised this, and publishes the following effusion, which, at any rate, is just as good as the best of the late Jubilee odes, not forgetting that of the Poet Laureate :—

My bicycle, my bicycle,
That standest idly by,
With silvered spokes, and plated hubs,
And gear extremely high,
No more shall I a-scorching bend
Above thy handle-bar,
Farewell, farewell, my bicycle,—
I've got a motor-car.

My bicycle, my bicycle,
By light of sun or lamp
We've covered many thousand miles,
We've sped through dry and damp;
But never more at dawn or eve
Shall I thy tyres inflate:
The times are changed, my bicycle,—
Thou art not up-to-date.

They tempted me, my bicycle,
My swift and silent steed,
With tales about a new machine
That goes at lightning speed;
And still serenely shall I go
Careering through the land,
Though thou art sold, my bicycle,
A bargain, second-hand.

My bicycle, my bicycle,
'Twill be no longer mine
To chase the flying pedals round,
No more I'll curve my spine;
But sitting idly at my ease,
I'll travel with the best,
For I shall turn a handle, and
The car will do the rest.

My bicycle, my bicycle,
It makes me smile with glee
To think how often we have made
The slow pedestrian flee.
With sudden sw-op we've come full [speed
Upon him from afar;
I'll do the same, my bicycle,
Aboard my motor-car.

Farewell, farewell, my bicycle;
Where flies the wayside dust
I'll haply chance to pass thee by
(Unless my boilers bust);
For wheresoever on the road
I journey, near or far,
It's my intent to make things hum
With my new motor-car.

ON A MOTOR-CAR.

Northampton to London—Experiences of Two Ladies.

THE first long-distance motor-car trip undertaken by ladies was accomplished last week by two women journalists—Mrs. Sutherland Morris, a writer, and Miss Amy Stewart, an artist, members of the staff of the *Gentlewoman*. Accompanied by Mr. Hawtrey, an expert on motor matters, they left Northampton at half-past twelve on a rather nicely-designed Daimler car, and, with a rest of an hour and a half at Dunstable for refreshments, reached the *Gentlewoman* offices in Arundel Street, Strand, at eight o'clock, having covered the 76 miles with only six hours' actual travelling.

Neither of the ladies had ridden upon a motor-car before, and both were extremely nervous at starting, Mrs. Sutherland Morris so much so that she made her will and left it at home with General Morris lest she might never return! But after they had travelled a little distance and discovered how easy the machine was to steer they became enthusiastic, and they reached town so fresh that it was evident they had thoroughly enjoyed their experience. At the offices they were welcomed back by Mr. J. T. Wood, the editor, and Mr. A. J. Warden, the manager, and also by a *Morning Leader* reporter. Our representative learned from Mrs. Sutherland Morris that down to Baker Street they came along splendidly. There had never been any appearance of a mishap, and the machinery had given no trouble. As their time made an average of nearly 13 miles an hour they must have sped along some whiles, for in Baker Street, Park Lane, Piccadilly, Charing Cross, and the Strand, they could get along but slowly, and had several stoppages in the dense traffic among the decorations.

INCIDENTS WERE NUMEROUS.

One of the first things they did was to break up a cricket match. As the car passed the whole of the players left the wicket and rushed to the hedge to watch them. Several drivers paid them much attention in the form of such requests for information as "Where have you left yer blooming horses ?" or by recommendations to them to "Hang on to your horses' tail, miss." At the hotel at Dunstable the ostler caused them much amusement by his surprise at receiving the customary tip, just as if he had "baited and brushed down." But one of the oddest incidents of all was caused by a man who had been sleeping on the grass beside the road. Suddenly waking up and catching sight of a smart carriage dashing along without horses, he began to gesticulate wildly, and cry out as if in danger, apparently being under the impression that he "had got 'em again."—*Morning Leader.*

THE DAIMLER MOTOR COMPANY'S "WAYZEGOOSE."

THE Daimler Motor Company, who are the first motor-car firm to inaugurate a periodical outing, have just held their first annual "wayzegoose," the place selected being Stratford-on-Avon. Over 180 of the employees took part in the excursion, which was conveyed to its destination by 20 vehicles, including three motor-cars of the Company's manufacture, whilst a neat launch, driven by a four H.P. Daimler motor, was available for trips on the river. The management of the affair was in the hands of a committee, consisting of Messrs. C. Bennyworth, C. Hatfield, R. Potter, W. Perkins, G. Needle, J. Simpson J. Blot, H. Needham, and P. J. Buddery, the latter making an excellent and most efficient hon. sec. and treasurer. After a substantial dinner a series of races were run off, the prizes in the evening being distributed by Mr. H. Sturmey, the acting chairman of the Company, after which he made a brief address to the men, calling their attention to the fact that they were engaged in the establishment of a new industry, and impressing upon all the fact that much of the future both of the industry and of the Company depended upon the good work done by each individual member of the staff. He assured them they had the finest factory and plant of machine tools for the manufacture of automotors not only in this country, but the world, and he hoped each one would make it a personal matter to see that his work was worthy of the machinery, the firm, and himself. Up to now, he told them, the Company had spent over £50,000 upon the fitting up of the factory, and the payment of their wages up to the point, and had as yet only received a few hundreds of it back, so they would see that up to the present they had had very much the best end of the stick. Of course, in the end the Company were hoping they, too, would get some of the good end, and he hoped all who were now enjoying the sweets would do their level best to the end that the Company got its share when the proper time came. If all worked with a will, and with one object in view, viz., the credit of the Company and its productions, he had no doubt that ere another wayzegoose came round there would be a very much larger number of workers to participate, and he assured the men it would not be the fault of the directors if there were not 500 men employed instead of 250 as now. After the usual vote of thanks, &c., the company returned home in every way satisfied with their day's enjoyment.

THE ROOTS OIL MOTOR AND MOTOR-CAR (LIMITED).

UNDER the above title a Company has been registered with a capital of £30,000 in £1 shares, for the purpose of manufacturing all kinds of carriages, cabs, omnibuses, and other vehicles for private and public traffic, propelled by oil-motors, and to purchase and carry on the business of Messrs. Roots and Venables, of 100, Westminster Bridge Road, London, and also deal with the valuable inventions of Mr. J. D. Roots and his firm, together with 12 patents for the United Kingdom for oil-engines, motors, &c., and 10 foreign patents connected therewith. According to the prospectus the Company also acquire all the licenses which have so far been granted under the Roots patents, lease and goodwill of the business and premises, plant, tools, machinery, &c., connected with the business now carried on by Messrs. Roots and Venables. Amongst those who are already manufacturing, or hold licenses to manufacture from the firm, are Messrs. Vosper and Co., of Portsmouth; Clark's Crank and Forge Company (Limited), of Lincoln; Bryan, Donkin, and Co. (Limited), of Bermondsey, S.E.; and amongst those who have applied for licenses to manufacture may be mentioned Mr. Walter, of the *Times;* the Central Engineering Works (Limited), of York; Mr. James Davis, Queen Street Iron Foundry, Wednesbury; and Messrs. Michael Tod and Son, of Devon Engine Works, Dunfermline. The estimated profits are moderately put down at £11,200 gross, giving a nett income of £9,210. Messrs. Roots and Venables' work has now stood the test of long trials, and they are at the present moment contractors to Her Majesty's Government, and have received numerous orders from the Indian and Colonial Governments, London, Brighton, and South Coast Railway Company, Liverpool Corporation Waterworks, &c. It is claimed that the Roots patents are master or pioneer patents for the system of vaporisation and feeding of oil, the essential points in an oil-motor, and the vendors believe that theirs is the only practical vehicle motor which runs with ordinary petroleum or paraffin. A very important point is that Messrs. Roots and Venables are in communication with the North Metropolitan Tramways Company regarding the fitting of a motor to their tramcars, which, if successful, would be fitted to all their tramcars.

The prospectus sets out very fully all the patents, trade marks, &c., which the new Company acquires, and a strong certificate as to the validity of the Roots patents is given by Mr. Lewis Edmunds, Q.C. The Board of Directors consists of practical men, who have earned an enviable notoriety for good business methods, and applicants for shares should note that no promotion money has or will be paid, and that there will be £12,500 available for working capital. The list of applications for the present issue (which is at 1*s.* per share premium) will open on Tuesday, the 20th July, and will close on or before Friday, 23rd July. Prospectuses can be obtained by addressing the Secretary, at the offices of the Company, 100, Westminster Bridge Road, London. Fuller particulars will be found in our advertisement columns.

The Paris-Dieppe Automotor Race.—This event, which is attracting considerable attention, comes off on the 24th inst., too late for detailed notice in our present number. It is being conducted under the auspices of the Automobile Club of France, which is equivalent to saying that the most distinguished French engineers are taking part in it. The municipality of Dieppe is doing everything to ensure success, and the proceedings will be further enlivened by a banquet and ball. Special trains will convey visitors from distant points. There will be four classes of vehicles—motor-cycles, weighing less than 200 kilos, automotor cars for two persons, automotor cars for more than two persons, and automotor cars carrying not less than six persons. The conditions of the contest seem to us to be very fair and equable, while the prizes are numerous, ranging from gold medals and 1,000 francs to 250 francs and objets d'art.

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

*** *At the request of a number of subscribers we are pleased to announce that for the future we have arranged to more thoroughly cover the field of completed Patents referring to the Motor-Car Industry, by reproducing the latest Specifications and Diagrams.*

Specifications Published.

9,151. Motor-Driven Vehicles. John Bradley Carse, 64 and 66, Wabash Avenue, Chicago, Illinois. April 30th, 1896.

Relates to the construction of the engine cylinders, two of which are made out of one piece of cylindrical tubing by splitting said tubing longitudinally for a suitable distance at the centre, and then opening out the split part until it is more or less flat. An opening is cut in the flattened part of the tubing and in it is a suitable bearing to receive the crank-shaft. The two ends of the tubing which remain intact form the cylinders proper, which are rigidly connected by the flattened part of the tubing, which flattened part may also serve conveniently for attaching the cylinders to the vehicle frame. The two connecting-rods of these cylinders work on the same crank-pin.

As applied to a tramcar or similar vehicle, four cylinders are formed in two pairs in the manner above described, and attached to the under frame of the vehicle between the axles and coupled to the same crank shaft, which is arranged centrally between the cylinders. From this shaft motion is imparted to either or both of the axles of the vehicle by chain gearing for example. Suitable clutches are provided for connecting and disconnecting the engine from the axles of the vehicle, so that it is not necessary to stop the engine in order to stop the vehicle. Also two speed gears, one for high speeds and one for slow speeds. One of these may be conveniently connected to the front axle and the other to the rear axle of the vehicle.

Another improvement relates to the connecting rods arranged to drive on to the same crank-pin. The outer end of one of the said rods is provided with a long bush that projects laterally for a sufficient distance to receive and form a bearing for the outer end of the other connecting rod. In this way the wear on the crank-pin is evenly distributed.

6,035. Gas and Oil Engines. Michael Carmichael Dunsmore, 4, Glebe Crescent, Stirling. March 8th, 1897.

This invention has reference to and comprises improvements in the construction or arrangement and combination of the parts of gas-engines, and in the construction or arrangement of the firing appliances, some of the essentials of which improvements are also applicable to oil-engines of the same class, whereby a motor stroke will be delivered at every revolution of the crank, with a rapid motion of the piston at the point of greatest expansion and a steady working of the engine be effected.

Figs. 1 and 2 are respectively a sectional elevation, and a plan of a horizontal gas-engine constructed in accordance with these improvements without showing the firing appliance.

Referring to these figures:—The cylinder, A, is formed as shown with the front part, A^1, of a less diameter and having the ordinary jacketting space all round fitted with inlet, A^3, and outlet, A^5, shown in the drawings for circulation of water therein to keep it cool. As shown the piston, B, is close ended and is formed with a trunk, B^1, of a diameter to fit the reduced front part, A^1, of cylinder, A, and fitted with packing rings, B^2, within which is joined the connecting rod, E, to the crank, E^1, A^4 being an orifice for lubricating the trunk.

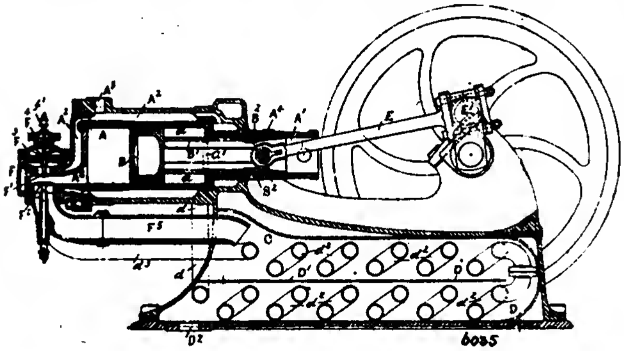

FIG. 2.

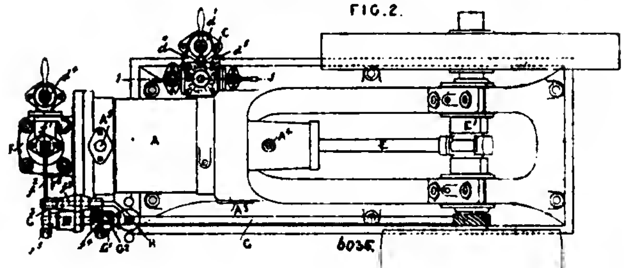
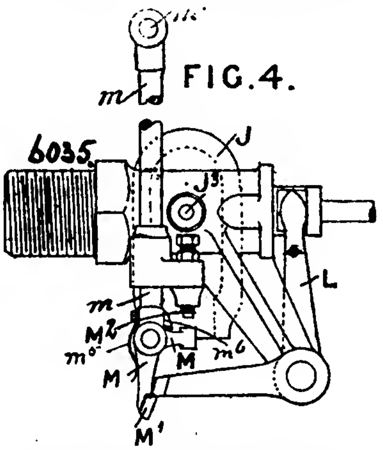


By this construction an annular space, a, is formed around the trunk, B^1, into which mixed air and gas is drawn during the instroke of the piston from the duplex inlet valve, C, through the port indicated at a^1 to be compressed during the outstroke of the piston. During the instroke the piston, B, the suction within the annular space, a, causes the valve to rise so as to allow gas from the gas-pipe fitted with a stop-cock or valve to pass through ports, and air from openings in calculated proportions to be drawn within the annular compressing space, a, through a passage and port. On the outstroke of the piston the mixture is compressed, and passing back by the port and passage shuts the valve and raising another valve passes to the storing chamber by the pipe, d. As danger of overpressure within the storing chamber, D, might arise, a check or governing piston valve is provided, regulated by a spring or a corrugated diaphragm may be used instead, which moves when the pressure rises to a predetermined amount and by its spindle acting on one arm of a bell crank lever causes its other arm to press upon a link and so prevent the valve from rising to admit gas and air. Instead of being allowed to work automatically the valve may be opened and closed by a lever placed transversely under the cylinder, A, and operated by a cam on the shaft, G, acting on one end, the other end being connected to the valve spindle by a link. The gas and air passes from the annular compressing space, a, by the pipe, d, fitted with a two-way cock or valve, d^1, to the storing chamber, D, which is preferably as shown formed in the base of the engine frame divided by a partition, D^1, and fitted with an undulating series of tubes, d^2, through which the compressed mixed gases circulate on their way to the cylinder by the continuation of the undulating tubes, d^2, and this pipe is provided with a non-return valve and stop-cock. Though this storage chamber is shown formed in the base of the engine it may be located otherwise and may have more than one series of tubes, or compartments, or other arrangements may be used instead of tubes, or where it is not desired to use the exhaust for heating a single storing vessel may be used.

A valve chest, F, is fitted on the cylinder and within which work the gas inlet valve, F^1, as shown, or which may be double ported, and the exhaust valve, F^2, actuated as to be described from the shaft, G, which receives its motion direct from the crank shaft of engine and makes one revolution for each revolution of same. The duration of opening of the valve, F^1, being regulated by the breadth of the kicker, G^2, at the point brought into contact with the antifriction roller on the lever, f^4, the sleeve, G^1, being acted on by the governor, H, by means of any ordinary forked lever arrangement not shown in the drawings. The end of the sleeve is left plain so that in the event of the load going suddenly off the engine the sleeve would be moved so far that the lever roller would run freely on this plain part and the valve, F^1, would remain shut. A piston valve, F^4, of larger area than the valve, F^1, or it might be a corrugated diaphragm, is fitted on the valve spindle, f^1, to close the valve, F^1, when the pressure of the lever, f^3, is removed. A flap valve may be employed either in front or behind the concentric rings to prevent the back flow of burnt gases,

FIG. 4.



or the concentric rings if made in two divisions, the lower one loose on the spindle, may act as a valve, one set of rings being made to coincide with the openings between the others so that when forced together by an explosion the passage of gas would be stopped.

Instead of concentric rings a series of flat bars packed or bolted together and resting in a square seat within the valve chest and kept at a small distance apart by projections may be used, or a series of flat rings may be used packed one above the other and separated by small pins or projections to allow the mixed gases to pass through from the outer annular space to the interior of the valve chest above the valve, F^1, otherwise the gas may be led to the interior of the rings, and through them to the exterior and down through the valve, which may be double ported.

The spent gases or exhaust pass from the cylinder by the port, A^6, through the valve, F^2, and pipe, F^5, to the interior of the storing chamber, D, to heat the mixed gases in the pipes, d^2, finally passing out at D^2. The exhaust valve, F^2, is opened at the proper time by the forked end of the bell crank lever, f^5, pressing the valve spindle upwards when its other end, furnished with an antifriction roller, is acted upon by the cam, G^3, on the shaft, G. When so desired the exhaust pipe may have an outlet to atmosphere fitted with stop cock or valve, so that the whole or part of the exhaust may be discharged without entering the storing chamber to heat the gases. If desired air only may be compressed and stored, and a separate gas pump be used to supply compressed gas to mix with compressed and heated air behind the piston.

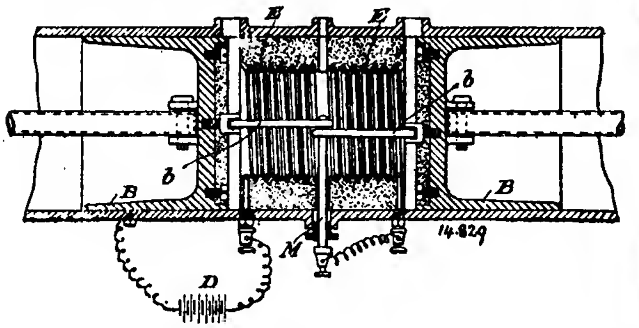
Fig. 4 is an elevation of a gas igniting appliance which may be used with the engine; this igniting appliance may be screwed into the valve chest, F. In this arrangement the ignitor, J, is formed as a close chamber and is supplied through the pipe, J¹, fitted with a stop cock with the compressed mixture of gas and air from the storage tubes, d^2, which passes into the interior through a fine orifice, a small ball acting as a valve to prevent the gases at explosion passing down the pipe, J¹. A plunger, formed at its inner end as a valve, working gas tight within a cylinder formed on side of the igniting chamber, J, when moved outwards by the action of the forked end of the bell crank lever, L, on the spindle against the power of the spring, opens the communication between the cylinder and the igniting flame by ports, while at the same moment communication with the atmosphere by the port, J³, is closed. Within the igniter, J, mantles of wire gauze may be fitted to retain heat sufficient to relight the gas jet after such explosion if necessary, or a small jet may be kept burning at mouth of port, J³. The movement of the plunger is effected by means of the angled projection, M¹, on the lower arm of the bell crank lever, M, jointed to the end of the rod, m, and fitted with reaction spring, m^5, and stop, m^6. This rod is jointed to the lever, f^2, and on this lever being released to allow the gas valve, F¹, Fig. 1, to close it draws up the rod, m, and bell crank lever, M, which engages with the bell crank lever, L, and moves the plunger outwards. When the arm of the lever, M, comes against the stop, M², it is oscillated to release the lever, L, when the plunger is driven inwards by the force of a spring to close communication with the cylinder.

14,829. Vaporising Arrangements for Oil or Inflammable Vapour Engines. Walter Rowbotham, 27, Vittoria Street, Birmingham. July 4th, 1896.

This invention relates to oil or inflammable vapour engines in which the engine is started when cold by means of a vaporiser, which vaporiser is electrically heated as described in the Specification of Letters Patent No. 22,793 of 1895.

In the use of such vaporisers it is found that if a current sufficient to heat when the engine is cold is kept on during the succeeding explosion, then the electrically-heated body is liable to become incandescent, and the oil, instead of being vaporised, is ignited at once, and even in some cases the wire may become so highly heated as to fuse.

The object of my present invention is to so regulate the electrical current applied to the vaporisers as to supply sufficient heat for the required purpose when the engine is cold, while automatically varying to reduce the current passed when the engine becomes hot.



Referring to the figure, to the ends of the pistons, B, B, are attached projecting fingers or rods, b, b, which rods, at or about the end of each piston's stroke (as in the position shown in the figure), make contact with a centrally-situated insulated rod, M, such contact completing the circuit through the battery, D (or other source of electrical supply), and the wires, E, E, of the vaporising body, and, by heating up the wires and surfaces, puts that body in a state fit for vaporising. When the engine starts, the movement of the pistons, B, B, make and break contact with the insulated rod, M, at each reciprocation, and thus as the speed increases the time during which the current flows through the vaporising wires, E, E, diminishes. As the speed of the engine increases the current passing thus decreases, and the heat added by the explosions succeeding each other takes the place of the heat at first generated by a powerful electric current. By this device the temperature of the vaporiser wires or vaporisor body is kept sufficiently low to avoid ignition of the oil when it is injected on the vaporiser, and also, of course, sufficiently low to secure the wires from any danger of fusion.

When starting the engine, the maximum current is needed to electrically heat the vaporising body, but the said current is in no case to be strong enough to render the vaporising body or any part of it incandescent.

It is obvious that after the first few explosions the heat generated will be such that if the current is not reduced the electrical vaporising body will become incandescent, and cause the hydrocarbon or spirit to fire before it is vaporised.

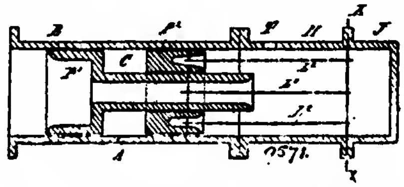
A modified form is also described.

9,571. Steam, Gas, and Other Engines. Count Charles Francois Gaston Louis Prosper de Chasseloup-Laubat, 51, Avenue Kléber, Paris, France. Date claimed October 31st, 1895. Date of Application (in United Kingdom), May 5th, 1896.

This invention relates to an engine or motor in which on the one hand the stresses and reactions upon the frame and the driving shaft, and on the other hand the inertia of the moving parts are balanced.

The improved engine or motor comprises:—

A cylinder, B, open at its two ends and containing two pistons, P¹, P²; one of which, P², is of annular shape and slides between the cylinder, B, and the sleeve or trunk carried by the other piston, P¹.



The pressure is exerted in the chamber or space, C, between the two pistons, P¹, P², which are thus driven in opposite directions.

For this purpose an opening, A, which serves both for the admission and for the exhaust, is provided in that part of the cylinder, B, which corresponds to the chamber, C.

The piston, P¹, with sleeve carries one connecting rod, L¹, and the annular piston, P², carries two connecting rods, L_2, L_3, coupled to cranks arranged at opposite centres to the crank of the other piston. The connecting rods are enclosed in a cylindrical box, H, which is fixed to the extremity of the cylinder, B, and closed at its free extremity by the bottom, J.

This box, H, is provided with an orifice, T, placing the interior of the box in constant communication with the atmosphere.

The total weights of each system (piston and connecting rods) are the same. It is evident that, under these conditions, the cylinder and frame do not undergo any reaction.

The bearings of the crank shaft are subject to a slight reaction only resulting from the non-parallelism of the connecting rods.

A modification is also described and illustrated.

11,058. Motor-cars, Autocars, &c. Ernest John Clubbe and Alfred William Southey, 16, Elm Street, Gray's Inn Road, London, and The Electric Motive Power Company (Limited), of 3, Salters' Hall Court, Cannon Street, London. May 21st, 1896.

This invention has reference to motor-cars or automotors and launches, and it consists in the combination in such cars or motors or launches of an oil or other internal combustion engine, a dynamo electric machine which acts alternatively as a motor and as a generator of electricity, a set of secondary or storage cells, and a switch, or switches preferably, actuated automatically by a governor or governors. The secondary or storage cells, which have been initially charged, are adapted to supply a current for the ignition of the explosive charge, and also for vaporising the oil where such is used, and also to supply the current to start the dynamo machine as a motor, together with the oil or other internal combustion engine. The carriage may be started simultaneously with the engine, or as soon as the latter has attained a certain speed. When the engine begins to run at full speed, a centrifugal or other suitable governor actuates a reversing switch, so that the dynamo machine, instead of acting as a motor, generates a current which recharges the storage cells. The lever used to start the carriage operates, in the first instance, to switch the current from the storage cells to the motor, the current being subsequently automatically changed in direction, so that the cells may be recharged. The same lever may be used, if required, to cut the dynamo machine out of circuit altogether.

The dynamo machine is geared with the shaft of the engine by spur or other gearing which allows for the difference in speed of the dynamo machine and the engine.

12,446. Improvements in Explosion-engines. James Carter and others, Billingshurst, Sussex. March 6th, 1897.

This invention relates to improvements in the explosion engine for which Letters Patent No. 9,889 of 1894 were granted.

According to the present improvements, instead of passing the oil inlet tube directly into the vaporiser as in the former patent, the oil is delivered in quantities sufficient for one explosion only into the open funnel or cup-shaped end of a tube in communication with the vaporiser and having a suitable valve. The petroleum is then sucked from the cup into the vaporiser and thence into the combustion chamber during the out-stroke or suction of the piston.

Instead of the valve regulating the admission of air to the vapour before its entry into the combustion chamber, the air inlet pipe is provided with a plate having a central hole, the diameter of which is made of the required size.

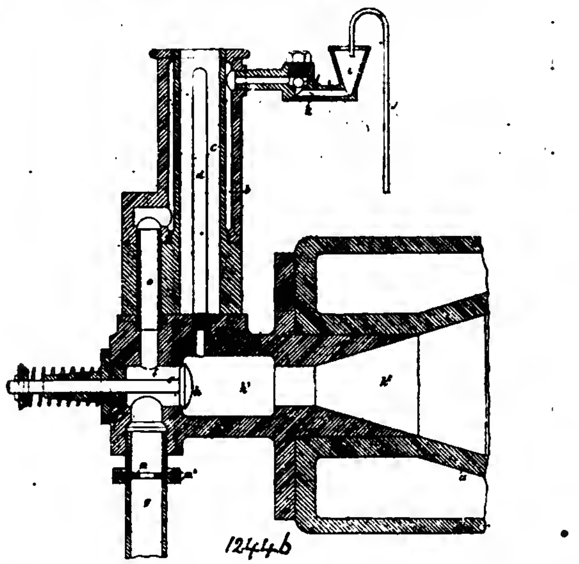
There is also a separate external combustion chamber in communication with the cylinder portion of the combustion chamber instead of the annular chamber through which the vaporiser passes, as described in the specification of the former patent.

a is the engine cylinder, *b* is the vaporising chamber which is formed around the tube, *c*, which serves as the chimney of the heating lamp as described in the said former patent, and *d* is the igniter arranged within the said tube.

e is the passage through which the vapour passes from the vaporiser to the chamber, *f*, and *g* is the air inlet pipe which also extends into the chamber, so that the air and vapour mix together as they flow past the valve, *h*, on the suction stroke of the engine, into the combustion chamber, h^1, which is the separate external combustion chamber hereinbefore referred to, h^2 being the cylinder portion of the combustion chamber.

i is the cup into which the oil is injected by the pump through a pipe, *j*, the cup communicating with the vaporising space, *b*, through the passage, *k*, in which a valve, *l*, is seated in such a manner that it will open automatically on the suction stroke of the engine to allow the oil injected into the cup to be drawn into the vaporising chamber and then again close on its seat.

m is the plate in the form of a disc, having a central hole arranged in the air inlet pipe, *g*, and serving to regulate the quantity of air



12446

drawn into the combustion chamber on the suction stroke, the plate being arranged between two flanges, m^1, on the pipe, so that it can be readily removed to alter the size of the hole or to introduce a plate having a larger or smaller hole, as required.

The List of Applications will open Tuesday, the 20th July, 1897, and will close on or before Friday, the 23rd July, 1897.

Messrs. Roots & Venables' Car was the only Petroleum Motor Car, of those collected for the *Engineer* Competition on June 1st, that did the run to Birmingham from the Crystal Palace, an account of which run is given in the *Engineer* of June 18th, 1897.

The *Times* of December 7th, 1896, speaking of previous motor carriages, says: . . . . "All these carriages used benzoline as fuel . . . . In England there is already in use a carriage of 'Victoria' form driven by ordinary lighting oil. It is the first carriage yet made which undoubtedly accomplishes this object, and is the invention of Messrs. Roots & Venables."

The Vendors believe that theirs is the only practicable vehicle motor which runs with Petroleum oil or ordinary Paraffin—a safe fuel—and that other practicable so-called oil motor vehicles use benzoline spirit—a dangerous fuel.

THE ROOTS OIL MOTOR & MOTOR CAR, LTD.

(ROOTS PATENTS.) **(Parent Syndicate)**

Incorporated under the Companies Acts, 1862 *to* 1893.

CAPITAL, £30,000, IN £1 SHARES,

OF WHICH £12,500 WILL BE AVAILABLE TO PROVIDE WORKING CAPITAL.

Payable, 5/- on Application; 6/- (including premium) on Allotment; and the balance (10/-) as and when required.

THE PRESENT ISSUE IS AT A PREMIUM OF 1/- PER SHARE.

No promotion money has or will be paid, and the Capital is not underwritten.

DIRECTORS—ALEXANDER McDONNELL, Esq., M.I.C.E. (formerly President, I.C.E., of Ireland; Locomotive Superintendent to North Eastern Railway and to the Great Southern and Western Railway of Ireland), The Rydens, Walton-on-Thames.
FREDERICK DAVID CHARLES SHAW-KENNEDY, Esq., Dyroch House, Kirkmichael, Ayrshire.
*JAMES D. ROOTS (Messrs. Roots and Venables), 100, Westminster Bridge Road, London, *Managing Director.*
*C. E. VENABLES (Messrs. Roots and Venables), 100, Westminster Bridge Road, London.
* Will join the Board after Allotment.

BANKERS—The NATIONAL PROVINCIAL BANK OF ENGLAND, Ltd., Lincoln's Inn Branch, Carey Street, W.C.

AUDITORS—Messrs. JACKSON, PIXLEY, BROWNING, HUSEY & Co., 58, Coleman Street, E.C.

REGISTERED OFFICES—100, Westminster Bridge Road, London.

ABRIDGED PROSPECTUS.

This Syndicate has been formed for manufacturing all kinds of Carriages, Cabs, Omnibuses, and other vehicles for private and public traffic propelled by oil motors, and to purchase and carry on the business of Messrs. Roots & Venables, of 100, Westminster Bridge Road, London, and also deal with the valuable inventions of Mr. J. D. Roots and his firm the aforesaid Messrs. Roots & Venables, together with the twelve patents for the United Kingdom for Oil Engines, Oil Motors, and for oil-motor vehicles of all kinds, and ten foreign patents in connection therewith.

To acquire the patent rights and business connected with the sale by Messrs. Roots & Venables of all oil, fixed and stationary engines, locomotive and portable engines, in addition to oil motors for all kinds of road vehicles.

To acquire all the Licences which have been granted to manufacture under the Roots' Patents.

To acquire the Lease and Goodwill of the business and premises at 100, Westminster Bridge Road, the plant, tools, machinery, engines, motors, and vehicles in stock and the drawings, patterns, etc., connected with the business now carried on by them as Engineers.

The following Licences have been granted by Mr. Roots:—

To Messrs. Vosper & Co., of Portsmouth, for marine and launch and boat engines, under which they pay a minimum royalty of £125 per annum, or £2 per indicated horse-power of each engine sold.

To the Clarke's Crank and Forge Company, Limited, of Lincoln, for portable and locomotive engines, the minimum royalty being £125 per annum, or £2 per indicated horse-power of each engine sold.

Messrs. Bryan Donkin & Co., Limited, of Bermondsey, S.E. (the well-known Engineers), have taken a licence for fixed or stationary engines, under which they pay a royalty of 10 per cent. on all Engines they sell. The Vendors also have the right to sell, and the Licencees are under contract to supply all Engines required on most advantageous terms.

There has been a total of nearly 300 Roots Oil Engines and Motors sold, and they are doing work in most parts of the world.

The Estimated Profits are £11,200, *see* Prospectus.

The Estimated Outgoings are £1,990, which leaves an Income to pay dividend of £9,210.

The Vendors have had many hundreds of enquiries for motor vehicles, not only from Great Britain, but from most parts of the world. The Vendors are Contractors to H.M. Government.

The Vendors have had applications from other English firms and from France for a Licence to make vehicle motors, but have now refused to treat or grant any further Licences at present.

The following are those who have applied for Licences to manufacture Engines or Motors under the Roots Patents:—Mr. Walter, of *The Times*, Queen Victoria Street, E.C.; The Central Engineering Works, Limited, York; Mr. James Davies, Queen Street Iron Foundry, Wednesbury; Messrs. Michael Tod & Sons, Devon Engine Works Dunfermline.

The Roots Engines have already, among others, been supplied to the Indian and Colonial Government, and also to the L. B. & S. C. Railway Company, the Liverpool Corporation Water Works, and the Sultan of Zanzibar. They are also in negotiation with the South Australian Government for small oil locomotives.

Engineers have on two occasions apologised for infringement of the Roots Patents, and it is fully believed that the Roots Patents are master or pioneer patents for the system of vaporisation and feeding of oil, the *essential points* in an oil motor.

The Vendors are in communication with the North Metropolitan Tramways Company regarding the fitting of a Motor to one of their tram cars, which, if successful, would be fitted to all their tram cars.

For light Railways the Vendors believe no other oil engine in the market can compete with theirs in the chief points required in a locomotive for this purpose, viz. (1) Lightness and small size for the power developed; (2) Completeness of combustion and freedom from smoke; (3) Complete automacity.

The Vendors believe they possess the only practical Oil Motor for vehicles in existence. The safety of the oil as fuel and the danger of the spirit will be obvious to everyone. Messrs. Roots and Venables therefore believe that for some time to come the Syndicate will have the monopoly, or almost the monopoly, of petroleum motor carriages, for it is believed that restrictions must presently be placed upon the use of benzoline spirit as to limit its use. Messrs. Roots and Venables, in short, claim that their Motor is the only safe Motor, and the only one at present in the market which will survive the test of daily and public use.

The running costs of the different kinds of Road Vehicle Motors compare as follows:—**The Roots Oil Motor, 1; Benzoline Spirit Motor, 3; Steam, 3½ to 4; Gasoline, 4 to 4; Electricity, 5 to ·.**

A Motor is in progress for Bicycles and Tricycles which it is believed will have almost a monopoly for the before-mentioned reasons, it being the only safe Motor. Carrier Cycles, for trade purposes, offer a large opening for the application of this Motor.

The following Trade Marks (with designs), belonging to Messrs. Roots & Venables, also become the property of the Syndicate:—"Petrocar" and "Petrocycle."

The Patents for the United Kingdom are numbered as follows:—

Improvements in Petroleum Engines	15,682	Nov. 3, 1888	Improvements in Internal Combustion Engines	17,308	Sept. 11, 1894
Ditto ditto	19,275	Nov. 7, 1891	Ditto ditto	2,138	Jan. 30, 1896
Improvements in Internal Combustion Engines for Vehicles	23,786	Dec. 24, 1892	Improvements in Self-propelling Carriages	9,677	May 7, 1896
Improvements in Internal Combustion Engines	22,181	Nov. 20, 1893	Improvements in Internal Combustion Engines	10,829	May 19, 1895
Ditto ditto	23,571	Dec. 7, 1893	Improvements in Internal Combustion Engines for Vehicles	14,756	July 3, 1896
Improvements in Oil Engines	7,538	April 16, 1894	Improvements in Petrocars or Motor Cars	17,270	Aug. 5, 1896

Several Provisional Specifications have also been filed.

Foreign Patents have been obtained or are in course of being obtained in the following countries:—
France. Belgium. Italy. Spain. Canada. India. Austria Hungary. United States. Russia.

Lease dated August 8th, 1895, of the premises 100, Westminster Bridge Road, not yet received.

The purchase price agreed to be paid to the Vendors for the acquirement of the above rights has been fixed at £17,500, payable as to £5,000 in cash, £5,000 in cash or fully-paid Shares, at the option of the Directors, and the balance of £7,500 in fully-paid Shares in the Company.

Re ROOTS' PATENTS.

Copy of Opinion by Lewis Edmunds, Q.C.

I have considered the Specifications of the following Patents of James Roots, viz.:—
No. 15,882 of the year 1888; No. 19,275, 1881; No. 23,786, 1892; No. 22,181, 1893; No. 23,571, 1893; No. 7,538, 1894; No. 17,306, 1894.
and I have also considered the Specifications of the prior patents set forth in the case.

I find that the inventions of Roots are adequately described and claimed, that they are useful and proper subject matter for the grant of Letters Patent, and that no one of the said Patents of Roots is anticipated by any of the said prior patents.

Temple, 11 *June*, 1896. (Signed) Lewis Edmunds.

A Contract has been entered into between the Vendors of the one part and John Lever of the other part on behalf of the Syndicate, dated 14th July, 1897.

There are numerous trade contracts relating to purchases of material, etc., and also contracts for orders, etc. Other agreements and arrangements have been and may be entered into with third parties as to the formation of the Company, and the Subscription of its Capital, to none of which the Company is a party. Applicants for Shares will be deemed to have had notice of the contents of all such agreements and contracts, and to have waived their right, if any, to particulars thereof, whether under Section 38 of the Companies Act, 1867, or otherwise.

Prospectuses and Forms of Application may be obtained from the Bankers, Solicitors, and at the Offices of the Company.

RAPIDITY. EFFICIENCY. ECONOMY.

"The greatest Labour-saving Invention ever offered to the Trade."

They will set any Section of Hoop, or Patent Channel Iron, on any sort or description of Wheel COLD, by Hydraulic pressure.

FRENCH MOTOR-CAR COMPETITIONS.

The Paris-Dieppe Race.

IN Great Britain the Press has with few exceptions adopted a distinctly unfriendly attitude towards automobilism, with the result that the industry of motor-car manufacture has been much hampered in its natural development. Even in those few cases where some attempt has been made to encourage the use of motor-cars, as in that unhappy *Engineer* competition, the effort has failed because the conditions demanded a degree of excellence attained in no existing automotor, whether this be a railway express engine or a light-oil tricycle. The British Press has indeed been woefully misinformed and has in its turn misled the public not a little over the automotor question. In France the Press has taken a much broader and more liberal view. French engineers and writers are quite aware of the defects of the various types of road motors and quite understand the limiting conditions of their employment. Instead of crying aloud on the housetops: "There is no really satisfactory motor," and abandoning the attempt to make one, they have very sensibly grasped the fact that, notwithstanding various defects in design and working, motor-cars can in nearly all cases economically replace horses. The French have, indeed, with the true spirit of progress, adapted themselves to the motor, and their efforts have been rewarded with a really astonishing amount of success. Take, for instance, tram-car propulsion; in Paris there are two systems of automobilism in use, both of which are, from the mechanical, economical, hygienic, and humane points of view, an absolute success. As we intend to describe the Paris tramways on a future occasion we need not now further refer to them. We may, however, remark that, as regards tram-car propulsion, Paris sets an example, which London, Liverpool, and Manchester, and other towns might well imitate. Indeed, on this question as on so many, many others, the average British town or county councillor is usually a hopeless ignoramus, and about as competent to discuss questions of traction as he is to decipher the Hittite inscriptions in the British Museum.

Few people in England except those concerned have an accurate idea of the extent of the motor-car industry in France. Not only are automotors used in tramways but also in vehicles used for social, professional, and business purposes. Indeed, the horse is being gradually but surely eliminated from the streets of the larger French towns. To the French Press as a whole must be given a large share of the credit for the achievement of this very desirable consummation. Under the auspices of various French newspapers several automotor competitions have taken place from time to time. The effect of these competitions has been to familiarise the public with automotors and also to remove prejudices against them.

The latest competition of this description was inaugurated by the proprietors of the two well-known Paris newspapers *Le Figaro* and *Les Sports* in conjunction with the Automobile Club de France, and consisted of a race from St. Germains to Dieppe, a distance of 171 kilometres, or 106 statute miles. It was held on July 24th. The motor-cars were arranged in four classes:—Class A included moto-cycles, that is to say, vehicles which weighed less than 200 kilos. = 440·8 lbs. tare without driver and stores; Class B comprised motor-cars carrying two persons side by side; Class C, motor-cars carrying more than two persons of which two are side by side; Class D, motor-cars carrying not less than six persons. Vehicles entered in the three latter classes paid an entrance fee of 50 francs, while those in Class A paid 20 francs.

As regards the conditions or articles of the competition these were simple and fair, bearing in mind that the object in view was merely to get over a stated distance in the shortest time

There were no restrictions except those indicated in the classes. It was, in fact, a go-as-you-please contest.

Of course such a competition has after all but little interest or value to the purely technical expert who wants data—in the present case unattainable. To the general public, however, who does not care a bit whether the engine of the train which conveys them to the seaside is a "simple" or "compound," or how it is propelled, the Paris-Dieppe competition is of great interest as it shows that really high speeds can be attained in practice, and that is all the public wants to know. We shall not then attempt to do more on this occasion than simply describe the proceedings, leaving our readers to form their own opinions as to the relative merits of the competing motors.

The prizes offered for competition were both numerous and costly. They were as follows:—

For the vehicle which accomplished the distance in the shortest time, irrespective of class, and quite independent of the prize attaching to its class, a gold medal given by the Automobile Club of France.

For the second vehicle, a silver medal given by the Automobile Club of France.

For the third vehicle, a bronze medal given by the Automobile Club of France.

For the first voiture built before January 1st, 1896, a prize given by the President of the French Republic.

For the first arrival in Class A an Objet d'Art of the value of 1,000 francs, in addition to an Objet d'Art of the value of the entrance money.

For the second arrival in Class A an Objet d'Art valued at 500 francs, in addition to another Objet d'Art valued at a quarter of the entrance money.

For the third of this class an Objet d'Art worth a quarter of the entrance money.

For the first arrival in Class B an Objet d'Art valued at 2,000 francs, in addition to another Objet d'Art worth half the entrance money.

For the second arrival in this class prizes the same as the second in Class A.

For the third arrival in Class B the same as the third arrival in Class A.

For the first arrival in Class C an Objet d'Art worth 1,000 francs, and another worth half the entrance money.

For the second arrival an Objet d'Art worth 250 francs, and another worth a quarter of the entrance money.

For the third arrival an Objet d'Art worth a quarter of the entrance money.

For the first arrival in Class D an Objet d'Art worth 500 francs and half the entrance money.

For the second arrival an Objet d'Art worth 250 francs, and another worth a quarter of the entrance money.

For the third arrival in Class D an Objet d'Art worth a quarter of the entrance money.

In addition to these prizes there was one, a silver gilt medal, offered by the Chamber of Commerce de Beauvais, which was given to the vehicle first passing through that town.

The following table gives the particulars of the entries:—

* Did not start. † Prize winners.

As will be seen, no less than 69 automotor vehicles were entered for the competition—a most gratifying testimony of the healthy state of automobilism in France, and a significant refutation of the absurd theory entertained in so many quarters in England to the effect that horseless traction cannot be effected by motors as at present in use.

On examining the list of entries it will be seen that there was but one steam motor, all the others being various types of oil motors; there was not a single electric motor-car, a fact which is to be regretted considering the liberal provision that had been made for obtaining fresh batteries if necessary on the way. It will be noticed, too, that no English firms competed, which is also a matter for regret. This absence of English motors is, we think, to be explained by the fact that for purposes of speed alone it is difficult to compete against the light spirit motors which are encouraged in France and barely tolerated in England, and which are not likely to be much used here.

The competition was made the occasion for a special *fête* throughout the district traversed by the motor-cars. Special trains were run from all adjacent towns to Dieppe. At the latter place the preparations were on a most extensive scale, the principal streets were decorated with flags and banners, while the municipality, under M. Roger, the Mayor, had arranged a series of festivities at the Casino. Nothing, in short, was left undone to secure the celebration of the competition with becoming *éclat*.

As showing the importance with which the competition was regarded in France, we may say that the Dieppe Municipality despatched one of its Councillors, M. Jubault, who was accompanied by M. Aubry, the editor of *Les Sports*, to London to personally invite Sir David Salomons and the members of the Self-Propelled Traffic Association to be the guests of the municipality. Unfortunately, Sir David was unable to attend, but the S.P.T.A. was ably represented by Mr. Worby Beaumont, M.I.C.E., &c., Mr. A. Barr (secretary), the Hon. C. S. Rolls, Mr. Stanley Spooner, Mr. Redwood (son of the distinguished Professor of that name), Mr. G. H. Little (technical editor of the Automotor, &c.). Most of these had travelled from London the night previous, and were met on arrival at Dieppe by members of the local committee, and escorted to the Hotel Royal and the Métropole, where they were the guests of the municipality, and furnished with a free pass for everything.

A very pleasing feature of the competition was the support and encouragement given to it by the authorities. Everyone from the prefect to the local gendarme did their utmost to make the thing a success. Nothing could exceed the courtesy and kindness of the various officials, especially to the foreign guests. The municipality of St. Germains and of the other towns passed *en route*, the Direction of Le Chemin de Fer de l'Ouest, and the municipality of Dieppe, under M. Roger, the Mayor, assisted by M. De la Rue, who was especially charged with the care and comfort of the English official visitors, did everything with the utmost tact and consideration. The arrangements were generally in the hands of a committee composed of members of the Automobile Club and others, but the actual executive duties were entrusted to M. J. H. Aubry, the editor of *Les Sports* and to M. Paul Meyan, of the *Figaro*. These gentlemen most ably discharged their by no means light duties, and were indefatigable in their efforts to promote the success of the competition. The former gentleman showed himself an expert starter and timer, and marshalled the motors like a general; while the latter acted as inspector-general, and saw that all arrangements were properly carried out *en route*.

At St. Germains M. L. Desoyer, the Mayor, made equally excellent arrangements, stationing policemen at the various points and level crossings so as to warn the drivers of the automotors of the approach of trains and in other ways to render assistance. In this task he was ably seconded by the principal residents, among whom we must not omit to mention M. Ledoray, an enthusiastic automobilist. A graceful act on the part of the inhabitants of St. Germains was the presenting to each driver of an automotor a bouquet ornamented with the national ribbons.

At the various road-junctions officials were stationed to indicate the route and to afford assistance, while at convenient intervals were stores of petroleum, coal, water, &c.; also at the level crossings on the railways the station-masters had special orders to facilitate the passage of the motors. Just fancy an English official of any kind whatever, whether a railway director, a local magistrate, a policeman, or beadle, facilitating in any way whatever the passage of a motor-car!

Baron de Zuylen de Nyevelt (President of the Automobile Club of France).

Soon after seven o'clock on the 24th ult. the motor-cars assembled at L'Avenue de la Grande Armée at St. Germains. The weather was beautiful, a nice westerly breeze was blowing, and the sky was cloudless. A large and fashionable crowd had assembled at the point of departure, and lined each side of the avenue. The motor-cars were not arranged in the order of their numbers, and this occasioned some little delay. One or two minor mishaps occurred, but among so many vehicles this could hardly be avoided. As nine o'clock approached, the various motors were mostly running light, and they were nearly all literally vibrating with suppressed energy.

As may be imagined, the noise made by so many machines, the excited words of direction from drivers to their attendants, the loudly-expressed comments of friends, the cheers of the crowd, made it impossible to hear oneself speak. Added to this were the heat and the dust, and one can picture the scene: it was like a Derby day at Epson, but without the vulgarity of the latter.

On the next page will be found a sectional chart showing the gradients, &c., on the route, together with the bridges, level crossings, &c.

At nine precisely the signal to start was given, and No. 2, a moto-cycle (A. Buisson), crossed the line; this was followed by others at intervals of 30 seconds. The scene was uow one of great animation and excitement, and soon the avenue was seen to contain a long line of rapidly-moving vehicles, the whole lot being despatched by M. Aubry in less than half an hour. As far as possible the cars were sent off in numerical order, but some did not arrive in time, and hence had to wait.

A special train had been chartered to convey the members of the Automobile Club and their guests from Paris to St. Germains, and from thence to Dieppe. Soon, after Rouen was reached it became a question whether it would arrive at Dieppe before the motor-cars, and the driver, to ensure this, put his lever another notch forward; the poor old automotor—she was 30 years of age—could not stand this very unusual proceeding, and something gave out. A long delay ensued, till a mail train

THE PARIS-DIEPPE GRADIENTS.

Alt
Lev
Ros
Bri
Bri

appeared and gently pushed the benighted "special" to its destination nearly an hour late, and fully half an hour after the first motor-car, a Bollée, had arrived. This unfortunate delay marred somewhat the reception of the vehicles, and much vigorous protest was indulged in against the directors of the Western Railway Company, more especially from those who, having been unable to catch the special, had to take the ordinary train, which occupied only six hours in traversing some 95 miles. A truly remarkable performance which we understand is repeated daily at intervals on that happy railroad.

The following table gives the times of departures, and arrivals of the motors at Dieppe :—

No.	Time of departure.			Time of arrival.			Time occupied (corrected).		
	h.	m.	s.	h.	m.	s.	h.	m.	s.

Just at the entrance of the Port of Dieppe, and close to the Western Crucifix which, with the eastern one, forms such a quaint and picturesque feature of the port, a large tent about 100 feet long by 50 broad had been erected and gaily decorated with flags and lit by arc lamps. This tent was for the accommodation of the motor-cars on their arrival. Men were here placed by the municipality to assist as cleaners and helpers. A large mound of sand and the local fire appliances were provided for possible contingencies, and it says very much for the intelligence displayed in the handling and use of such large quantities of motor-naphtha as was involved in running so many vehicles, that no accident whatever occurred. We attribute this largely to the superior technical education given in France to the artisan classes.

On arrival at Dieppe the motor-cars, escorted, or rather followed, by a most enthusiastic crowd, proceeded to the tent and were subjected to a very necessary cleaning process, all of them being covered in dust.

The run to Dieppe was uneventful as regards accidents, the most serious being the capsizing of a Bollée voiturette, which was owing to bad steering. There were a few minor mishaps arising from slack joints, but, speaking generally, all the motors

Fig. 1.

ran splendidly. At one time the race seemed to have resolved itself into a contest between a Bollée and a Panhard carriage, but at Arcques-le-Bataille the former broke down owing to a defect in the ignition tube, and it had to abandon the contest.

Fig. 2.

The honour of victory nevertheless remained with another Bollée, viz., No. 45, driven by M. Jamin, who rode with remarkable *verve* and skill. This gentleman arrived in 4 hours 13 minutes 33 seconds, being followed a few minutes later by the

De Dion steam brake. The next arrival was M. Charron on

Comte Albert de Dion (Vice-President of the Automobile Club of France).

minutes 34 seconds on the journey, or at the rate of 24·5 miles per hour, while in Class D, the winner was M. Courtois, who drove a Delahaye wagonette, which did the distance in 5 hours 58 minutes 13 seconds, or at the rate of 17·7 miles per hour. It will thus be seen that the performances are remarkably good. To analyse them and appreciate them fully we require to know the horse-power developed, weights, and other particulars, of which it is extremely difficult to obtain reliable information, and what is available is not too reliable. Thus the steam wagonette of Count de Dion is officially quoted as being of 6½ horse-power, but it is easily seen that the actual horse-power must be nearer 26. In view of this absence of accurate data we have not thought it necessary to describe the vehicles at length, more especially as most of them have already been described, and in most cases illustrated, in our columns.

The prizes were awarded as follows:—In the moto-cycle

section. Class A. the first and second prizes went to MM.

opinion of those conversant with the art of carriage building this brougham is the best example of the application of an oil motor to a private visiting carriage that has yet been produced.

In the evening there was a banquet given by the Baron de Zuylen at the Casino, the English delegates being specially invited, and which was attended by several of the leading inhabitants and most of the *chauffeurs* who had taken part in the race. On the following day, Sunday, the 25th, there was an exhibition of the motor-cars, the various prize winners each received a silk banner which was attached to the respective cars, and thus adorned they careered round the Marine Promenade and paraded the entire town at a speed which would deeply shock some of our provincial Bumbles. Notwithstanding the crowds, no accident occurred, the motors being under perfect control. It was a very fine sight to see so many motors so well handled and for the most part presenting a very smart appearance. In the evening there was another banquet at the Casino, followed by a concert and ball. At the banquet 150 guests were present, including M. Roger, the Mayor of Dieppe; M. Hendlé, Prefect of

FIG. 3.

the Seine-Inférieure; the Baron Zuylen de Nyevelt, President of the Automobile Club of France; Comte Albert de Dion, Vice-President of the Automobile Club of France; MM. Breton (Deputé), Lee-Jortin (Dieppe English Consul), Jubault, de

FIG. 4.

Lucenski, Aubry, the delegates from the Self-Propelled Traffic Association, De Bouton, Avigdor, Bollée, &c., &c.

There were the usual speeches of an enthusiastic description in favour of automobilism, M. J. H. Aubry proposing the health of Sir David Salomons and the members of the Self-Propelled Traffic Association, in which he asked the *chauffeurs* to drink to the health of their English colleagues. He then added, in English:—"Gentlemen, we are very happy to driuk in your presence to Sir David Salomons's health, to yours, to the members of the Self-Propelled Traffic Association, and to the spreading of our common ideas and feelings all over the United Kingdom."

As will be gathered, the Paris-Dieppe competition was a huge success, reflecting credit on all participating in it, and it was fittingly concluded by festivities which were, if anything, on a rather too extensive scale. The greatest courtesy and cordiality were manifested towards the English visitors, who one and all came away with the impression of having had a most instructive and pleasant visit. It only remains for us to congratulate the municipality of Dieppe, the Automobile Club, and our contemporaries *Les Sports* and *Le Figaro* upon the success which has deservedly attended the competition. We do not, however, congratulate La Compagnie de l'Ouest. When so many have facilitated our task and rendered it pleasant, it were perhaps invidious to mention names, but we cannot conclude without expressing our sense of the services rendered us by MM. Aubry, Jubault, and De la Rue. For ourselves we are glad to have assisted in doing some little thing towards building up *l'entente cordiale* between France and Great Britain which we trust may never be disturbed.

The illustrations which appear in connection with the Paris Race are:—

Fig. 1. The carriages in the early morning at St. Germains taking up their positions opposite their numbers fixed on the trees.

Figs. 2 and 3. The vehicles being started by M. Aubry.

The Manchester Steam Users' Association.—At a special meeting of the Committee of Management of the Manchester Steam Users' Association, Mr. C. E. Stromeyer, Graduate of the Royal Technical College at Aix-la-Chapelle, Member of the Institution of Naval Architects, Associate Member of the Institution of Civil Engineers, Member of the Institution of Mechanical Engineers, Member of the Institution of Engineers and Shipbuilders in Scotland, and Engineer Surveyor to Lloyd's Register, Glasgow, was appointed Chief Engineer in succession to the late Mr. Lavington E. Fletcher.

Water required for Condensation.—The amount of water required thoroughly to condense the steam from an engine is dependent upon two conditions, the total heat and weight of the steam and the temperature of the injection water. Generally stated, with 26 inches vacuum and injection water at ordinary temperature—not exceeding 70° F.—from 20 to 30 times the quantity of water evaporated in the boilers will be required for the complete liquefaction of the exhaust steam from an engine. Our American contemporary, *Power*, gives the following formula to estimate the value of water for condensing purposes under any specific conditions:—Given, I = temperature of injection water; D = temperature of discharge water; S = total heat—sum of sensible and latent heat—of the steam at the pressure at which it leaves the engine. This varies from 1140 to 1158 units, as the terminal pressure is 10 lbs. or 30 lbs. absolute; it may, however, be taken as 1150 for ordinary purposes. Then $\frac{S - D}{D - I}$ = unit weight of injection water required per unit weight of steam. Example, I = 70° F.; D = 110° F., with a vacuum of 26 inches; S = 1150 units of heat. Hence $\frac{1150 - 110}{110 - 70} = 26$. That is, the weight of the injection water required will be 26 times the weight of the steam exhausted.

COMPRESSED AIR LOCOMOTIVES IN NEW YORK.

Two compressed air cars are at work experimentally in New York. The air is first compressed by a steam-actuated air compressor, which is compounded in three stages, from which the air passes through a cooler and dryer, and is accumulated in a nest of Manuesmann steel flasks, which are all connected in multiple by a series of headers or manifolds, in which stop valves are placed for controlling and confining the air to be stored at a maximum pressure of 2,500 lbs. per square inch. A pipe leads from this air storage to the car house charging stand, placed alongside the track, which consists of a copper pipe in three sections, having a controlling valve and flexible joints and a charging nozzle at the end. After the car has been connected by inserting the nozzle in a pipe at the side of the car track, the charging valve is opened, and contents of the station storage flasks admitted until the desired pressure—2,000 lbs. per square inch—is registered by the car storage gauge. At the same time the car is being charged with air, another nozzle is introduced to the heater connection, and live steam from the boilers is admitted, until the temperature registered is about 300° F. The air storage reservoirs on these cars have a capacity of 51 cubic feet, sufficient to run the car 18 to 20 miles continuously, or from 14 to 17 miles, making the stops incident to ordinary street railway service. Between the flasks and the motor is placed a small tank containing 6 cubic feet of water, which is heated as before described. In operation, the compressed air, after passing through a reducing valve and being lowered to 150 lbs. to the square inch – the working pressure —circulates freely through the hot water, and a mixture of heated air and vaporised water passes to the motors, working expansively, the terminal pressure being so low as to cause no sound in exhausting the air. The motor mechanism consists of two simple link-motion reciprocating engines having cylinders 7 inches in diameter and 14 inches stroke, with valves cutting off at from $\frac{1}{10}$ to $\frac{1}{6}$, and applying the power by connecting and parallel rods direct to the crank pins of the driving-wheels, which are four in number, 26 inches in diameter, running on a wheel base of 7½ feet.—*The Engineer.*

M. J. H. Aubry.

(Organiser of the Paris-Dieppe race, editor of *Les Sports*, and great grandson of Cugnot, the inventor of the first steam carriage, which is now in the Paris Museum of "Arts et Metiers.")

["England and France look to the future of automobilism as through an opera-glass. France looks through the big end and sees carriages little, and light, and speedy; England through the small end and sees heavy, and strong, and steady. We complete each other: business and pleasure resume life."—J. H. A.]

THE SUPPLY OF PETROLEUM TO MANCHESTER.

An important business, entirely new to Manchester, but common to nearly all other large seaports, will shortly spring up on the banks of the Ship Canal below Mode Wheel Locks—namely, the importation and storage of cargoes of oil in bulk, says the *Chemical Trades Journal.* Since the opening of the canal, consignments of mineral lubricating oil, petroleum, &c., have been imported to the Manchester docks in steadily-increasing volume, but owing to the absence of accommodation for dealing with oil carried in tank steamers, all such consignments have arrived in barrels. Notwithstanding this drawback, last year's shipment of oil to Manchester, by way of the canal, amounted to 17,449 tons, as compared with 8,155 tons in 1895, and there is no doubt that if storage tanks had been available the importation would have been much larger. There are already two large oil tanks which have been erected by the Manchester Corporation Gas Committee on a piece of ground adjoining the Foreign Animals Wharf at Old Trafford. They will be used exclusively by the committee for their own purposes, and it is expected that about 20,000 tons of oil will pass through them every year. This will, of course, be imported in tank steamers from America or Russia. A development of even greater commercial importance is, however, the establishment of similar depôts for oil imported for general use. Two large tanks for the Liverpool Oil Storage Company are now in course of erection on the Old Trafford side of the canal, and it is said that this Company is making preparations for dealing with a trade of 60,000 tons per annum. It is stated, also, that several acres of land on the opposite side of the canal have been purchased by a Russian oil syndicate, which intends to construct similar tanks, and expects to do an equally large business. A local firm has already established an oil manufactory near Mode Wheel Locks, and the Canal Company is to construct suitable wharves on both sides of the waterway.

THE AUTOMOBILE CLUB OF GREAT BRITAIN.

UPON the invitation of Mr. Frederick R. Simms the first official meeting of the above-proposed club was held on Tuesday, the 10th inst., at the suggested club premises, No. 4, Whitehall Court, Thames Embankment. Although the original purpose of the meeting was to appoint officers of the club, pass the regulations, &c., the Hon. Evelyn Ellis (Chairman) stated that for the moment it was premature to go into details, either financial or otherwise, or to discuss other matters in regard to the proposed club. The only question that need then be entered upon was the securing the premises for 12 months, whilst the club itself was being formed. Mr. Simms, he was glad to announce, was prepared to guarantee the rent and expenses for the first year, and also the preliminary expenses in regard to the formation of a Company for carrying on the club. Mr. J. B. Purchase was appointed solicitor, and was instructed to register by October next the Automobile Club of Great Britain, either as a Limited Liability Company, or preferably as a Company limited by guarantee to £1 each subscriber, and it was arranged to adjourn the meeting to some time in October, when all the details, &c., would be fully laid before those attending. Among those present were Earl Galloway, Gen. Sir Arthur Ellis, Hon. Evelyn Ellis, Col. Lea, Messrs. E. Elieson, C. Heyermans, Hiram S. Maxim, Walter Arnold, A. Cornell, A. Fairlie Allingham, Robert Beadon (on behalf of P. E. Singer), J. H. H. Berkeley, J. D. Roots, Arthur E. Heming, E. E. Sherwin Holt, J. B. Purchase, &c.

The Noise Made by Petroleum Burners.—Mr. J. S. Bickford, of Camborne, Cornwall, in writing to a contemporary, says:—"This noise has been certainly a great obstacle to the use of petroleum for steam raising, but it is an objection which can no longer be urged with justice. I am willing to supply on approval to anyone of good financial standing petroleum burners capable of consuming any quantity of oil per hour with comparative silence. No doubt some of your readers will smile at 'comparative silence,' but I cannot claim absolute silence. The burner makes very much the same noise as a gas fire, only slightly more so. Degrees of noise are very difficult to express in writing, but some idea can be gathered of what is intended by 'comparative silence' when it is said that a conversation can be carried on in an ordinary voice across one of these burners whilst it is consuming more than one gallon of oil per hour."

The Storage of Carbide of Calcium.—Since the Order in Council of February 26th, 1897, in virtue of which certain parts of the Petroleum Acts, 1871 to 1881, were applied to carbide of calcium, the question of the expediency of exempting small quantities of this substance from the operation of the order has occupied the attention of the Home Office, and the Secretary of State, having been advised that such exemption might be safely extended to quantities of carbide of calcium not exceeding 5 lbs., when kept in separate, substantial, hermetically-closed metal vessels containing not more than 1 lb. each, an Order in Council was made on July 7th, authorising the keeping of not more than 5 lbs. of carbide of calcium in vessels as above described without a licence, and the orginal order of February 26th has been amended accordingly. The amending order appeared in the *London Gazette* of July 9th. It is to be observed that where the carbide of calcium is not kept in vessels as above described, no quantity may be kept without a licence.

CONTINENTAL NOTES.

THE Messageries Maritimes Company have lately acquired an electric launch built by an English firm for service in the East.

WE understand that M. Hospitalier, the well-known French electrical engineer, is preparing a work on electrical automobilism.

THE petition against the proposed tax upon automotors which has been lying at the office of *Les Sports* has so far received 18,300 signatures.

WE regret to learn that the motor-car factory of M. Roger et Cie., of Paris, has been partially destroyed by fire. The loss is, however, covered by insurance.

THE Northern Railway of France is trying various systems of automotors. It has for its postal and local services steam motor-cars on the Serpollet system and Petro motors on the Panhard and Levassor systems.

THERE is being constructed in France an automotor carriage which will be 24 feet 6 inches long by 8 feet by 8 feet. It will comprise three separate apartments—a dining-room, kitchen, and conveniences; it will be hauled by a De Dion and Bouton tractor of 30 H.P.

THE new Berlin Omnibus Company, says the *Elektrotechnische Zeitschrift*, intends to run a trial accumulator vehicle, and the order for its manufacture has already been placed. It is to be of the same size as an ordinary omnibus, with seats on the roof, and the cells will be placed both under the inside and outside seats. The cells will be charged after every two journeys.

A FRENCH contemporary devoted to automobilism has been quoting rapturously about a certain Mlle. Christiane, who, we are pleased to hear, rejoices in being a "blue-eyed blonde with carnation cheeks" and a "Parisienne of Paris," who has, to employ the English vernacular, "chucked the bike" for a motor-car, because the latter is more fashionable. We rejoice to hear it.

THE directors of the Compagnie Générale des Voitures à Paris state in their report that it is their intention to transform a number of their cabs into auto-cabs, and that they prefer the use of electricity to petroleum for propulsion. According to the *Eclair*, 500 electrically-driven cabs of different types were to have been on the streets of Paris on July 1st; a fortnight after one type was to be chosen as most suitable, and the work of transformation of all the cabs will be begun immediately, and completed in less than a year.

AMONG recent additions to the membership of the Automobile Club of France we notice the names of W. Worby Beaumont, Esq., M.I.C.E., &c., Mr. Boveton Redwood, jun., and the Hon. C. S. Rolls. This latter gentleman is an ardent automobilist and is one of our most experienced amateurs. He is at present entered as an "undergrad." of Cambridge, and has wisely gone in for the engineering course. He will thus in time become an authority upon automobilism. Mr. Rolls has lately purchased the four-seated Panhard and Levassor voiture, of 8 H.P., which was the winner of the Paris-Marseilles race, it having covered the distance of 1,077 miles in 67 hours 42 minutes, or an average speed of 15·5 miles per hour.

LES POIDS LOURDS

OR

THE HEAVY-WEIGHT MOTOR-CAR COMPETITION.

While it has been very generally recognised that under certain elastic and easily-fulfilled conditions, light vehicles could be moved by other than animal power with a considerable measure of success and economy, it has been doubted whether it would ever be a commercial possibility to replace horses for the traction of heavily laden wagons. Indeed, not a few people have loudly proclaimed that in vehicles of the usual dimensions, it would not be possible to include the motive machinery and the usual load, especially if the latter was at all bulky. It has been forgotten that, as we pointed out in a recent issue, the effective length of any horse-drawn vehicle or the length of the space occupied must logically include that space occupied by the horses, because, if these be removed, the motive power departs. All doubts on the question may now be said to have been removed by the heavy motor-car trials that have lately taken place in France under the auspices of the French Automobile Club. These trials were, in fact, the outcome of much uninformed and crude opinion expressed in various ways by various persons and journals both in this country and abroad; and at one time it seemed not improbable that, owing to such uninstructed opinion, automobilism would be relegated to the background as a harmless relaxation of the leisured classes. On the other hand, there was the accomplished facts of the early English pioneers in heavy horseless traction, and it was rightly urged that with modern material and the use of higher steam pressures, space and weight taken up by the motive machinery could be reduced to a relatively small proportion of the total capacity and weight. In order to ascertain the actual possibilities of heavy motor-cars, the French Automobile Club inaugurated a series of trials to take place early in the present month at Versailles. These trials were of a purely technical and practical character, and although, of course, speed was an important element there was no premium placed on it, or, in other words, there was no racing; hence the competition did not attract that notice on the part of the general public as did the Dieppe and Trouville contests, but was followed very attentively by those who are more seriously interested in heavy motor traffic. Thus the French Minister of War appointed Lieut.-Col. Laval and several officers to attend and report, while the German military officers attached to the German Embassy evinced great interest in the trials. It is no secret that the military authorities entertain a high opinion of the possible utility of a well-designed and powerful tractor for operations in the open country. Steam, however, is not favoured for the motive power but petroleum is preferred. The Self-Propelled Traffic Association sent over a delegation consisting of Mr. W. Worby Beaumont, M.I.C.E., Cantor Lecturer on Horseless Traction; Mr. H. Hartley West, M.I.N.A., M.I.C.E., Naval Architect and Consulting Engineer; Mr. A. W. Barr, Secretary; Mr. Shrapnell Smith, Honorary Secretary Liverpool Branch. There were also present, though unofficially, Sir David Salomons, Bart., and Professor Boverton Redwood, F.I.C., &c., President and member of Council respectively of the S. P. T. A. Among others present were Mr. Sydney Lawson (of Birmingham), the Hon. C. S. Rolls (of Cambridge), Mr. Redwood, jun., Mr. A. Hopkins, Mr. H. Pope (representing Colonel Pope, of the Pope Manufacturing Company, U.S.A.), and Mr. G. H. Little (technical editor of the Automotor). The place selected for the trials was Versailles, near Paris, and as will be seen a better one could hardly have been chosen, as the gradients are many and steep, and the country roads much as country roads usually are.

M. Forestier.

(Commandeur Legion d'Honneur, Engineer-in-Chief Les Ponts et Chaussées, President of the Poids Lourds Technical Commission.)

M. Paris Singer manifested his interest in the competition by depositing the sum of 5,000 francs with the Automobile Club of France for the purchase of medals, &c., for distribution among the competitors.

The trials took place on August 5th, 6th, 7th, 9th, 10th, and 11th, and were conducted by a Technical Commission appointed by the Automobile Club, under the presidency of M. Forestier, Commander of the Legion of Honour, and Engineer-in-Chief of that admirable branch of the French Service, Les Ponts et Chaussées. The members of the Commission were MM. Franck, Courtois, Pilon, Audibert, Boyer-Guillon, Méry Picard, David, Dalifol, Daniel Augé, Frontin, Despinois, Longuemare, Ferns. Several gentlemen voluntarily undertook the office of technical observer. They were MM. Vinet, Rueff, Vedovelli, Raymond, Victor Popp, Gastyne, De Rouvre, Drion, Pigornet.

The principal points to which the Commissioners were to direct their attention and to which they were to give due appreciation were:—

- Smell and noise of exhaust;
- Visibility of exhaust vapour, particularly in the case of steam;
- Vibrations;
- Ease of suspension;

Noise made by the machire in motion;
Degree of comfort of the vehicle;
Dust and dirt made by working the motor;
Power of the motor, facility of steering;
Change of speeds, whether easily accomplished or not;
Ability to stop and start on inclines;
Necessity or otherwise of going backwards in order to obtain momentum in mounting an obstacle;
Necessity or otherwise of lightening the vehicle when starting;
Efficiency of brakes for stopping on and descending gradients;
Lubrication:
Proper capacity of bunkers and feed tanks;
Seizing of the machinery;
Breakage of any part;
Leakage of steam, feed water, or fuel;
Condition of feed pump;
Pressure gauge, and in oil-motors condition of ignition apparatus;
Regularity of explosions and feed;
Proper circulation of cooling water;
Supply of oil, how carried.

It will be seen that the Commissioners had to report upon every detail, and hence the trials may be regarded as the most searching that have yet taken place. It is, however, to be regretted that the Commission did not cause to be issued with each entry a small dimensioned sketch giving full particulars as to weights, power, speed, &c.

Description of the Vehicles.

We regret that, owing to the extreme disinclination on the part of the builders of the various motor-cars to furnish us with working drawings and details our description of the motor-cars is necessarily imperfect and incomplete. This reticence to impart information is hardly calculated to impress possible purchasers, and we fail to see that any useful object is gained thereby; there is nothing secret about motor-car design as there is, or was, about torpedoes, and a good design appearing in the technical Press would most likely, as it often does, lead to business. However, we must content ourselves with such particulars as we have been able to obtain. As will be seen from the following table, 15 vehicles were entered for the trials:—

The first three are trains on the Scotte system, the distinctive feature of which is a motor-car, itself conveying goods or passengers, hauling another car. There is nothing at all remarkable about this system either in the general design or the application of the motive power. The motor-car is a 4-wheeled one carried on a channel iron frame and supported on the axles by ordinary plate springs. The wheels are very heavy and massive, but notwithstanding this they show evident signs of stress. We may as well here remark that we observed this in the wooden wheels of all the heavy tractors. To transmit some 25 to 40 H.P. through a built-up wooden structure, such as a wheel, passing over rough roads, is in our opinion a mistake, and shows a lack of appreciation of the intensity and direction of the stresses transmitted and the strains produced. The front part of the motor-car consists of tanks which form the bunkers and feed tanks; behind these are placed the boiler on the left and the engines on the right. The boiler is a modified "Field," working at about 10 atmospheres, or 142 lbs. per square inch, and has, we should say, about 120 square feet of heating surface. The motor is a two-cylinder vertical non-condensing engine, on the shaft is a sprocket wheel and chain which drives a second motion shaft, which, in its turn, drives by similar means the rear wheels. Steering is effected by worm-gearing actuating the front axle through a toothed wheel. No. 1, Fig. 1, is a train for passengers, and consisted of a motor-van and a trailing passenger van. In the motor-van there is seating accommodation for 14 persons. The trailing van has three compartments: the one in front being for baggage, &c., the middle one for 12 passengers, and on the rear platform there is room for six more. The motor gives off about 16 H.P. when running at 400 revs., the steam pressure being as before stated, the speed attained on a good road being 12 to 14 kilometres, or from 7½ to 8½ miles per hour.

Train No. 2 is a goods train, composed of a motor-van, which carries 2,500 kilos. = 5,500 lbs., and a wagon which can carry 9 tons, the total weight carried is thus nearly 12 tons. The boiler and engine are similar to the foregoing, the bunkers have a capacity for 440 lbs. of coke, and the feed tank holds 176 gallons of water. This train can go from 10 to 18 miles without replenishing, at a speed of from 4 to 6½ miles per hour, depending upon the road.

Train No. 3 consists of a motor-car and passenger omnibus with seating capacity for 24, and a baggage capacity on the roof of 800 lbs.

No. 4, Figs. 2 and 3, is a steam omnibus by Weidknecht, of

N.B.—1 ton = 1,000 kilogs. = 2,200 lbs.

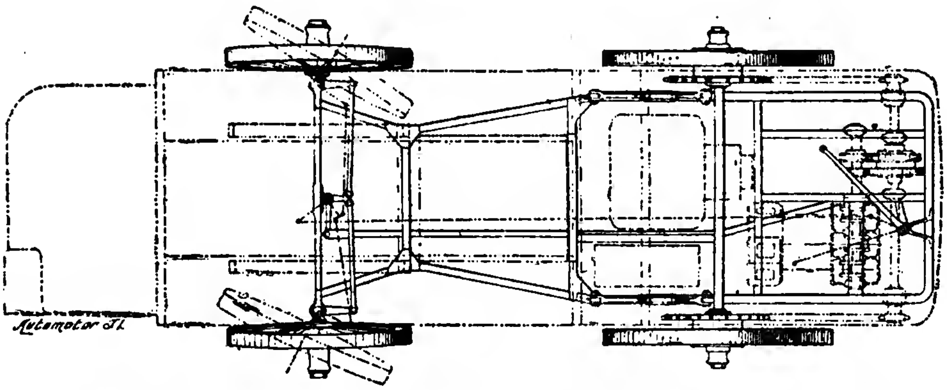
Fig. 1 (Official No. 1).—"Scotte" System—Motor-Car and Trailer.

Paris. As in the "Scotte" the forepart is occupied by the boiler, motor, bunkers, &c. The boiler is a tubulous one and the working pressure being about 210 lbs. per square inch. The motor is a three-cylinder compound, and can develop from 25 to 35 H.P., the engine running at 300 revs. Chain gearing is used to transmit the motion from an intermediate shaft which is driven by pinions. The driving wheels are about 5 feet in diameter. The total weight of the omnibus is about 6 tons fully laden, and the speed attained varies from 7 to 9 miles per hour. Its appearance is decidedly heavy and cumbrous.

No. 5 is a steam cart by Gaudon. The boiler is a tubulous one and is fired by liquid fuel, the motor is a four-cylinder simple engine which, when running at 350 revs., gives off about 10 H.P. The weight of this cart when fully equipped is about 3 tons, and it can carry about 4 tons.

This motor-car did not, however, run in the competition, although entered.

No. 6, Fig. 4, was a Le Blant brake for 12 persons. It was built in 1892, and was the winner in 1894 in the contest inaugurated by *Le Petit Journal*. It has been slightly altered since then by the addition of a roof and another seat. It is driven by three-cylinder steam motor having cranks 120 degrees apart, working as a simple engine. On the crank shaft are pinions carrying chain which transmits the motion to the rear



Figs. 2 and 3 (Official No. 4).—Weidknecht Motor-Car (Elevation and Plan).

wheels in the usual way. Steam at a working pressure of 10 kilos. per square centimetre = 142·2 lbs. per square inch is supplied by a Le Blant boiler which is a modified Serpollet. At 250 revs. the power developed is about 12 H.P.

Both boiler and motor, together with the bunkers, tanks, &c., are placed on the front of the car, the rear part being taken up by four seats. On the roof 500 kilos. = 1,100 lbs. can be carried. The wheels are of iron and are of heavy construction. The carriage is carried on springs in the usual manner. Steering is effected by a hand-wheel which gears into the front horizontal

No. 10 was a Panhard and Levassor omnibus, constructed to carry 10 passengers and their baggage, the latter on the roof. There is a 12 H.P. Phœnix oil-motor, having four cylinders arranged in the manner customary with this firm. The water for cooling purposes is contained in a tank which holds sufficient (what this may be we are not informed) for a run of 30 miles. The motor is geared for four speeds, and the speed ranges from 2½ to 9½ miles per hour. The total weight is about 2½ tons.

No. 11 was a light parcels delivery van, made by the Anglo-

Fig. 4 (Official No. 6).—Le Blant Brake.

wheel surrounding the pivot. The weight of the car empty is about 3,500 kilos. = 7,714 lbs.

No. 7 was a Le Blant train, composed of a steam tractor, Fig. 5, towing a goods-wagon laden with 10 tons of ballast. This train is intended for the mineral traffic. The engine is a two-cylinder one fitted with Walschaert valve gear, and works with steam at a pressure of 10 kilos. or 142 lbs. per square inch; at 180 revs. per minute it develops 60 H.P.

No. 8 was a Bollée oil motor-wagon built by the De Dietrich Company, and is designed to carry a load of about 1 ton or more at a speed of 9½ miles and on moderate grades at 3½ miles.

French Company, of Birmingham and Paris. It is driven by a horizontal motor having two cylinders, and develops about 10 H.P. As we hope to describe this car, with drawings, in our next number, we need not now further refer to it, except to say that this van will carry about 1 ton of goods and seemed to be well adapted for its purpose.

Although entered for the competition, at the last moment was withdrawn.

No. 12 was a Le Blant tractor, built in 1894, attached to an omnibus, Fig. 6, having a seating capacity for 24 and a baggage capacity of 600 kilos., or 1,320 lbs. The motor is a wo-cylinder

2 H 4

engine a bye-pass valve is fitted whereby high pressure steam can be at will admitted to the low-pressure cylinder. When running at 600 revs., the engines develop 25 H.P., and the speed is about 7½ miles. The bunkers will hold four hectolitres of coke and about 100 gallons of water, sufficient for a run of 20–21 miles.

No. 14 was a De Dion and Bouton omnibus, seating 14 passengers. The arrangement of the boiler and machinery is similar to the foregoing example. The speed is about 10½ to 11 miles per hour, and the weight of the car about 4½ tons. A feature of the De Dion and Bouton motors is the use of Cardan joints, by which considerable freedom of movement between the driving and driven shafts is permitted.

No. 15 was a char-à-banc, built for the Maison Parisienne, seating 12 persons, and driven by a Benz motor of about 9 H.P. It can carry about 1 ton of goods.

A feature common to nearly all these vehicles was the use of brakes on the axles or hubs

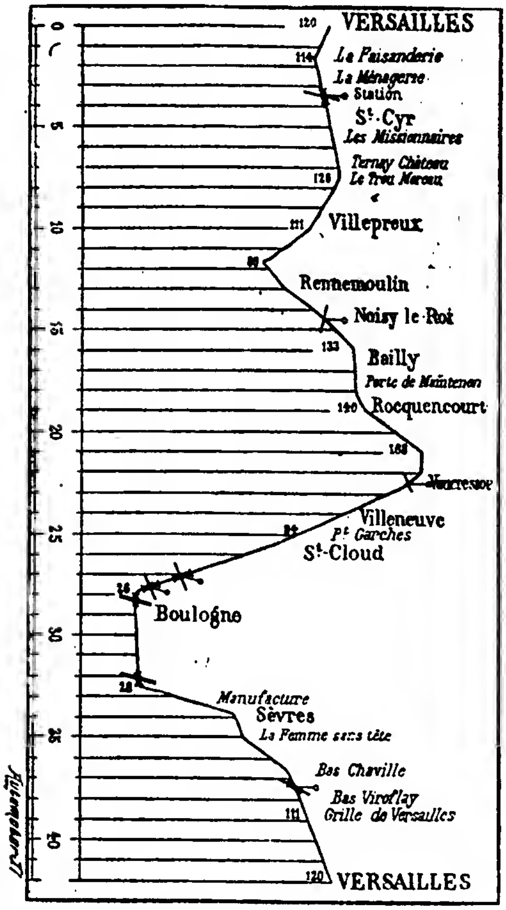
Rocher de Caucale, which looks upon the Place d'Armes, in front of the Versailles Palais.

Description of the Routes.

The nature of the gradients on the various routes will be seen by the accompanying profiles.

Three different routes lying around Versailles were selected, denominated respectively Routes A, B, and C. Route A was from Versailles to St. Cyr, Villepreux, Noisy-le-Roi, Rocquencourt, St. Cloud, Porte de St. Cloud, Sevres, Viroflay, to Versailles; the total distance being 41·3 kilometres = 25·6 miles, of which 11·20 kilometres, or 6·9 miles, was made or macadamised road.

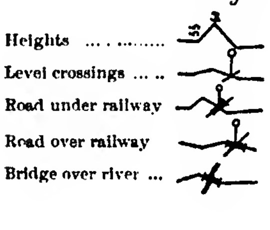
Route A.



Route B was Versailles, Ville d'Avray, St. Cloud, Suresues, Puteaux, Neuilly, Porte Maillot, back again to Rueil, Pecq, Saint-Germain, Marly-le-Roi, Rocquencourt, Versailles; the total distance being 45·9 kilometres, or 28·35 miles, of which but 3·47 miles was macadamised or paved.

Route C was Versailles, Satory, Port Royal, Dampierre, Bois St. Robert, Cernay-la-Ville, Chevreuse, St. Remy, Gif, Orsay, Palaiseau, Igny, Jouy-en-Josas, Versailles; the total distance being 66·1 kilometres, or 40·98 miles.

Signs and Scales.



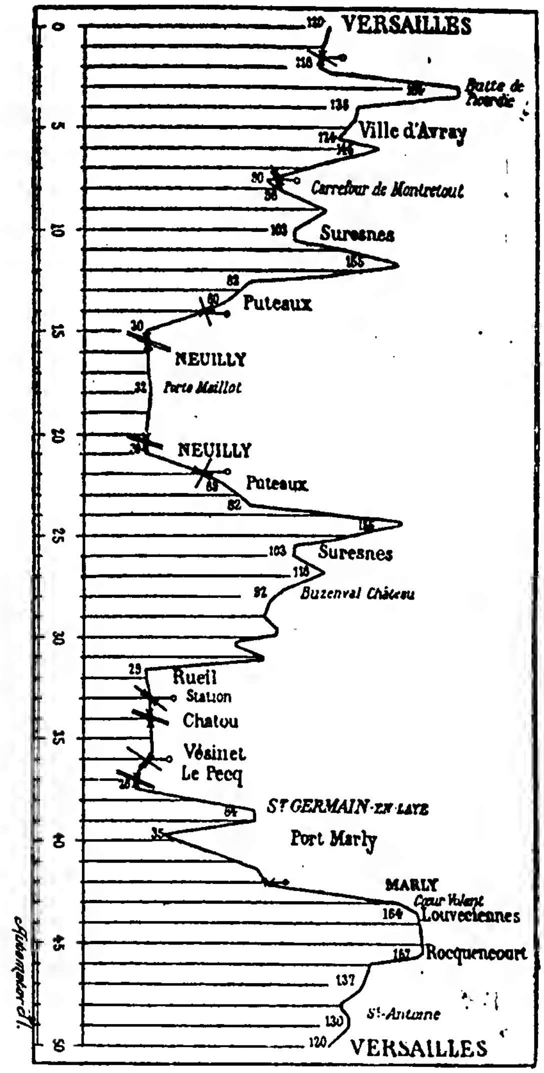
Scale, 2 mm. = 10 metres for heights.

„ 2 mm. = 1 kilometre for distances.

At various points on the route were stopping-places for taking on board fuel, water, &c., but only 15 seconds at each stopping-place was permitted.

From these profiles it will be seen that the routes are distinctly hilly, and well calculated to test the qualities of motor-cars. But one other condition was necessary to make the test perfect, and that was mud; and this was not wanting. The first three days of the trials were characterised by very

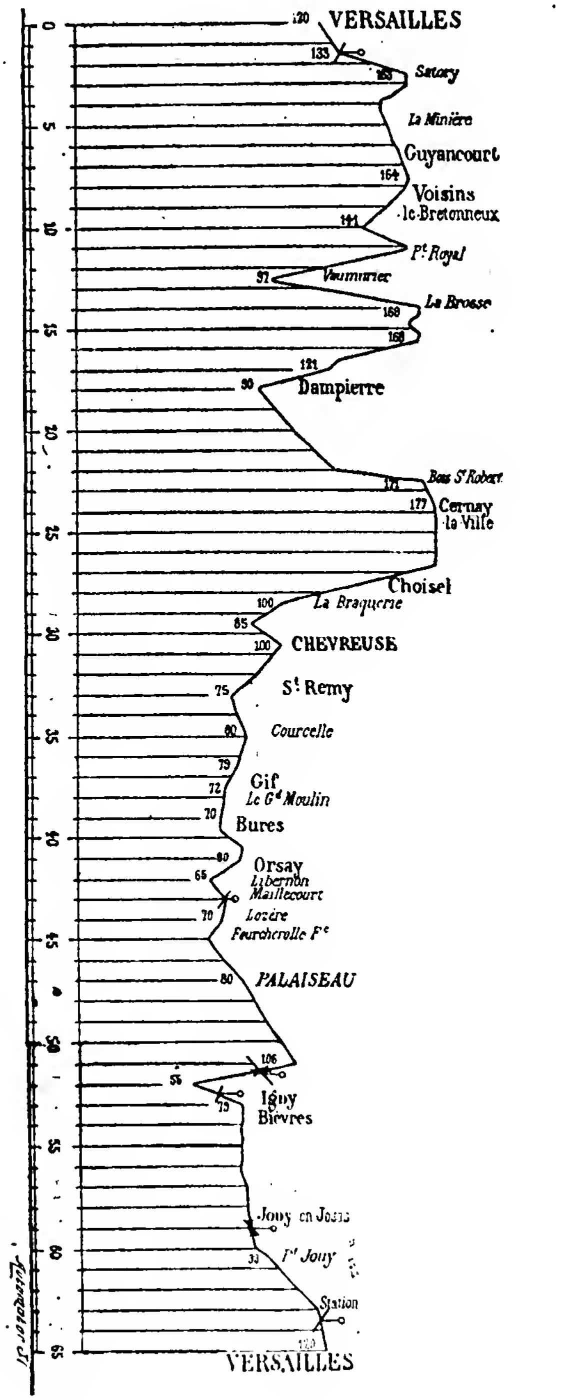
Route B.



hot dry weather, and the roads were miniature Saharas for dust, which was blown about in dense clouds, particularly near Versailles, and this not only got into one's eyes and nostrils, but blowing into the exposed working parts of the motors, especially such parts as chains, &c., added to the severity of the tests. On August 8th there was a good 12 hours' rain all over Paris and its environs, and the roads, notwithstanding their general excellence, made the going very difficult for the remainder of the trials. Thus, then, the tests were very severe, and hence are of great practical value.

As we go to press we have not yet received the Judges' report, and hence cannot give the official results. Any private judgment on the performances that we might have formed would, unless based upon official data, be invidious; we therefore withhold our criticism for the present. We may, however, say that, speaking generally, all the competing vehicles underwent the trials in a very satisfactory manner, and completely demonstrated the feasibility and economy of

Route C.



heavy motor traction. In our next issue we shall analyse the data.

LAW REPORTS.

Traction-Engine v. Motor-Car.

At the Holt Petty Sessions, last month, Ephraim Allen, locomotive proprietor, of Cley, was charged with a breach of the Locomotive Act at Briston, on July 5th. Police-constable Dunn said that on the morning of that day he saw a traction-engine. Seeing no one in front of it, he stopped it and asked the driver why he had not a man walking in front, as required by law. He replied it was unnecessary since the alteration in the Act. Witness told him he had no notice of such alteration, and bade him conform with the regulations. He, however, rejoined he knew he was right, and rode on. In the afternoon witness met the same engine and driver near Melton Constable railway-station. As there was no one in front of the engine he again spoke to the driver, who again affirmed that there had been an alteration in the Act. Both of the places at which he met the engine were dangerous.

The defendant said that with the driver and stoker he sent a man to walk in front of the engine. His son told him that he had heard that the Act had been altered. Defendant had pressed him as to whether he was sure on that point, not wishing to get into trouble.

Mr. C. W. H. Cozens-Hardy thought that possibly the son was thinking of the Act passed last year with reference to motor-cars.

The defendant admitted his responsibility, and the Chairman advised him to know more about what Acts were passed. Fined 2s. 6d., and 3s. 6d. costs.

Sir W. E. J. Vavasour's Failure.

At the London Bankruptcy Court, on August 10th, the case of Sir William Edward Joseph Vavasour, Bart., was on the list of public examinations. The debtor, who is described as of Alexander Square, W.; Hazlewood, Tadcaster, Yorkshire; and Draycott, Stoke-on-Trent, has during the past twelve years devoted the greater part of his time to the study of electricity, and has invented various improvements in electrical appliances. He has acted as the managing director of the Akester Electric Motor and Accumulator Company (Limited), &c. By consent of all parties the examination was adjourned until next November.

Tyre Case.—Important Judgment against the Dunlop Company.

Pneumatic Tyre Company (Limited) v. Ixion Patent Pneumatic Tyre Company.—On August 4th Mr. Justice Wills gave judgment in this case, which was an action brought by the Pneumatic Tyre Company (Limited) and the Dunlop Pneumatic Tyre Company for an injunction against the Ixion Patent Pneumatic Tyre Company, to prevent them from infringing the Dunlop tyre patent which was granted to Mr. Welch in 1890.

The chief feature of the Dunlop tyre, it was said, was that it was saddle-backed with inextensible edges, and with wires that held it rigidly in position. The alleged infringement consisted of inextensible edges secured by a flat band of metal sewn into a sort of pocket.

The defendants denied the alleged infringement, and contended that the patent was invalid, inasmuch as the completed tyre showed disconformity with the provisional specification.

His lordship held that the real question between the two parties was whether the bands of the Ixion tyre really depended upon tension, and on that point he had come to the conclusion that whatever might be the other forces at work in the Ixion tyre, the effective balance of force which held the tyre in position was the power of compression or contractile force. He gave judgment for the defendants on the issue of infringement and in the action, and on the question of the validity of the patent he gave judgment for the plaintiffs. He directed that the taxing master should tax the costs as if the defendants had succeeded *in toto*, and then knock off one-third of the amount, as the defendants had raised the question of the validity of the patent.

THE LAW OF PRESS CRITICISM.

The recent action of Mr. Wicks, of Wicks' Patent Syndicate (Limited), for alleged libel against the *Financial Times* has been the means of placing on the law records one of the most satisfactory definitions of the duties of the public Press in regard to the criticism of wild-cat schemes and other ventures when offered for public subscription under the Limited Liability Acts. Although we are not concerned to discuss the merits of the value of these patents, it appears that the *Financial Times*, having a full knowlege of the invention, very rightly placed their opinion of the value before their readers, and we, with the whole of tbe Press of the United Kingdom, rejoice in the good fight fought by our financial contemporary which has culminated in what will be a memorable judgment for all those concerned with candid Press criticism. The duties of the public Press could not be more clearly defined than in the words of Lord Russell, the presiding judge, who during his summing-up said :—

"This at least is clear—that when an individual or a company goes to the public with such an announcement as this preparatory, as it is admitted, to asking that indulgent public to contribute money, and to contribute large sums of money, the persons who take that step at once expose themselves to public criticism. Nay, they invite public criticism, and it is not merely the right, but I would go even further, and say it is even the duty of a public journalist who purports to be interested in and to advise the public upon financial concerns, to criticise closely and severely, avoiding misstatements of fact if they involve libel—avoiding imputation of motives if they are not able to justify them, but criticising thoroughly—aye, and I will even add severely—the claims to public support which these persons are making. If there ever was a time in which a jury, in my judgment, ought to hold the shield of protection over an honest journalist, who is honestly criticising the claims of these promoters of companies to public support, this is the time. A journalist who, for a sordid or interested motive, dishonestly attacks persons or companies ought to come under the very strongest and severest condemnation of a jury ; but the journalist who, honestly desiring to do his duty, warns the public to scan, and scan closely, the schemes that are presented to that public, and in relation to which they are asked for large pecuniary support, such a journalist deserves every protection that the law can give him."

Although we, during our brief but successful career, have without fear or favour criticised certain financial schemes which have come within our sphere, we are nevertheless glad to recognise the substantial good done by the *Financial Times* in obtaining, at what must be considerable cost to themselves, such a very explicit and satisfactory statement of the law, and one so useful and valuable to the Press at large.

NEWCASTLE STARTS ANOTHER MOTOR-CAR.

A fortnight ago a new motor-car started from the Haymarket, Newcastle, for a run to Morpeth and back. The van was built by Messrs. Harris, coachbuilders, of the Haymarket, to the order of a company that owns a new proprietary medicine. Like a tramcar, it has a door at each end. The motive power and driving gear were made by Messrs. Toward and Co., St. Lawrence, Newcastle. The coachbuilders and engineers worked to each other's hands, and their joint production is the smart-looking vehicle shown in the illustration. The motor power is steam, the steam generator being of the light water-tube type, on an improved principle. In adopting the water-tube type of boiler instead of the "flash" or "Serpollet" type, Messrs. Toward and Co. state they have been influenced by exhaustive experiments with both classes, and although there are some good points about the latter they consider the balance of advantage is so largely in favour of the former that they have decided to adopt it in their motor-car machinery. A few of the principal advantages which Messrs. Toward and Co. say they find are "freedom from excessive heat, large reduction in weight, great saving in time in first lighting and getting on to the road, absolute reliability of steam supply and pressure under all conditions, economy of fuel, and economy of space occupied." The boiler is 20 inches square and 24 inches high, contains 55 feet of heating surface, and weighs 550 lbs. It is stated to be capable of evaporating 350 lbs. of cold

Steam Motor-Van by Toward and Co.

water per hour, and discharging it at 200 lbs. pressure on a consumption of 1 lb. of coke for each 12 lbs. of water evaporated. The evaporation required for driving the van at a speed of, say, about eight miles an hour is about 160 lbs. an hour, at 100 lbs. pressure. There is thus a large excess of power at command. The steam-engines are of the horizontal high pressure type, and drive through an intermediate shaft with differential gear and sprocket wheels by chains to the two driving wheels which have rubber tyres. The starting and reversing levers, and steering handle, pressure gauge, &c., are all arranged in front of the driver. The start from the Haymarket was made at a quarter past two, the bridge at Morpeth being crossed at a quarter to four o'clock. The return journey was begun at half-past six o'clock, and Newcastle was reached a little after half-past eight o'clock, after a smooth journey without untoward incident of any kind, the machinery having worked without a hitch.

Naval Automobilism.—The Thames Valley Launch Company, of Weybridge, have, we understand, delivered 14 electric boats from their works since last September, two being for Chester, one for the Government, one for the Southport Corporation, one for Llangollen, and others to different places on the Thames, or elsewhere, for use on rivers, canals, lakes, &c.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10*th of each month. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be sent to the Advertising Department, F. KING AND Co., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., *including prepaid postage to any part of the world. Single copy* 7d., *post free.*

Cheques and Post Office Orders should be made payable to F. KING AND Co., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

SPECIAL NOTICE.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents*:—

London: POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale: BRETT AND Co., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. MCCANN, 37, Union Street.
Manchester: JOHN HEYWOOD, Deansgate.
Newcastle-on-Tyne: C. C. ROSS, 35, Side.
Paris: HOMÈRE MOREAU, 97, Rue Nollet.
Victoria (Australia): PHILLIPS, ORMONDE, AND Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. *for* 12 *months' subscription, post free (or at the rate of* 7d. *per copy).*

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

AUGUST 18TH, 1897.

ANSWERS TO CORRESPONDENTS.

WANDERWEIDE (Amsterdam).—We regret to say No. 1 is entirely out of print. You might possibly get one privately.

T. H. (Preston).—We are sorry you had so much trouble. There should be no difficulty in obtaining our paper at Smith's bookstalls. We would suggest you writing direct to the firm's head office complaining of the matter, when it would be sure to have immediate attention.

TYRE (Bolton).—The particulars you send read like a fairy tale, and we must certainly decline to give publicity to the details which you send until we have had an opportunity of completely testing your statements. If correct you evidently have a fortune before you.

MECHANIC (Londonderry).—If you apply to Jessop Browne, City Wheel Works, 104, Great Brunswick Street, Dublin, you will find he can supply you with exactly what you want.

B. L. (Coventry).—It is useless to use packing for high pressure steam joints. Face up your joints properly and use copper wire. After steam is up give an extra squeeze in all nuts.

W. W. (Cardiff).—We have not heard anything further about the steam motor-van you mention. Ask Thornycroft's of Chiswick.

F. K.—You will find an oil strainer in your tank a useful thing. You can easily make it from wire gauze.

C. H.—Indicating an oil motor is a thing which requires good manipulative skill and knowledge. Examine the piston.

W. P. (Birmingham).—We do not recommend rubber tyres for heavy motor-vans.

R. G. (Newcastle-on-Tyne).—So far as we know the Elswick firm have not made any military motor-vans. We understand that the War Office is, however, watching the development of motor-car propulsion, especially for ambulance service.

T. A. (Hampstead).—Boilers for motor-cars are not subject to Lloyd's or the Board of Trade surveys. We should advise the construction to be under the supervision of one of the large boiler insurance companies, who would assure you against risk. No, the driver need not be certified.

AN AUTOMOBILE CLUB FOR GREAT BRITAIN.

We have received from Mr. F. Simms a letter which appears in our correspondence column announcing the projected formation of an Automobile Club for Great Britain. It is, of course, very desirable that a club for the purposes indicated in the letter should exist, but it is also essential that the conduct of the club should be in hands unconnected with commercialism. Without impugning in the slightest degree the *boná fides* of Mr. Simms, we think that his connection with the commercial side of automobilism would operate as a deterrent to many who would otherwise gladly associate themselves with such a movement. It was, we believe, this feeling which operated to prevent the success of the Motor-Car Club, the failure of which to command success appears to give our correspondent "some sorrowful feelings." Clubs and kindred institutions when run for commercial ends undoubtedly tend to become a "single man's institution," to again quote our correspondent. Whether the Self-Propelled Traffic Association comes within this category is a question of fact, and so far as our knowledge of it goes, we should say it was not. As its name implies traffic is its *raison d'être*, and hence the social aspect of automobilism hardly comes within its purview, and so far as we know it is not, at any rate, intended that it should. The Motor-Car Club, on the other hand, was ostensibly social in its aims, but was really a commercial adjunct to a business and hence did not command the support of the leading British automobilists, and therefore failed. The great success of the French Automobile Club has been due to the salient fact that it was established by a body of gentlemen for the purpose of promoting automobilism in all its aspects. Its policy is a single-minded one, and it welcomes to its ranks all who, otherwise suitable, are interested in automobilism. It by no means discourages engineers and manufacturers; on the contrary it includes in its ranks persons who commercially are necessarily keen business rivals; but commercial interests are not allowed to sway its policy. The fact that its committee is composed of some of the most distinguished French public gentlemen is guarantee enough for that; and we are sure that it is to this disinterested and patriotic desire on the part of the committee to foster an industry, which we, also with "some sorrowful feelings," admit is coldly regarded by an unenlightened British public, that the splendid success of the Automobile Club of France is due.

His Excellency the President of the French Republic is glad to recognise the efforts of the Automobile Club of France and officially encourage it. We are not aware that any public man of high rank supported the Motor-Car Club for reasons which we have hinted, and which are sufficiently well known to render any further reference superfluous. It will interest our readers to know that an Automobile Club, although not the one referred to by our correspondent, is in the process of inception, and it will comprise many distinguished English names, and will also have the recognition and support of the French Automobile Club, which we may say will hardly be accorded to the institution referred to by our correspondent. Not but that the latter might not equally merit such support. We do not say nor imply that it would not; the fact, however, that the gentlemen promoting the latter are, if we mistake not, interested in the commercial aspects of automobilism is, to our mind, fatal to its success. Our remarks may appear to many to have the effect of throwing cold water on what, for aught we know to the contrary, may be a perfectly legitimate institution. We must, however, point out that Mr. Simms does not furnish us with the names of his supporters, and hence his prospectus is, to say the least, premature. It is true that a few gentlemen attended an informal meeting held at the proposed club premises on the 10th inst., but we are not aware that any large subscriptions were forthcoming, nor was there much support from those most prominently associated with the industry. We observe, too, in looking over the proposed rules that the latter are largely a transcript of those adopted by the Automobile Club of France. This is not a bad thing *per se*, but it does strike one as an odd coincidence that this prospectus and rules should be issued just at the time when another club having aims and policy similar to tho Automobile Club of France is being started. Mr. Simms may, of course, plead that owing to "such critical times" his scheme admits of no delay, but that a club is necessary to save the British motor industry from utter annihilation. We are not aware that the times are "critical." We claim to know what is being accomplished, and we should say that, so far from being critical or fraught with tribulation, the present times are distinctly propitious for those engaged in the legitimate automotor industry. The British public does not readily grasp new ideas, and it has not quite assimilated the economic possibilities of automobilism. This opaqueness has, however, its good point, as it acts as a salutary check upon those who would otherwise exploit new and immature industries. In this light the abortive trials, exhibitions, and competitions of and between motor-cars in Great Britain have been of great value—hardly, perhaps, to their promoters, but distinctly so to the public. Inasmuch as the public is only just beginning to see the advantages of automobilism, there is no particular haste for the formation of any club. We should prefer to see any such formation proceed on deliberate and well-considered lines, and accompanied by the disinterested moral and financial support of persons in high station who are alive to the needs of promoting automobilism, not so much as a sport or relaxation for the well-to-do, but as a means of promoting and facilitating internal commerce and transport. We are not aware that these views were enunciated at the recent informal meeting, and we certainly are of opinion that before definite steps are taken, and if success is to be assured, possible members should be fully informed as to these points.

THE COMPENSATION FOR INJURIES ACT.

This measure, perhaps one of the most important pieces of social legislation ever attempted, has at length become law, and takes effect from July, 1898. The principle of the new law is, briefly, that persons injured while following their employment deserve to be cared for by their employers. Such a distinctly altruistic doctrine is at first sight startling, and one's amazement is not lessened by the fact that this socialistic principle has been endorsed by a Conservative Government. The consequences of the new law will be very far-reaching, and the first will undoubtedly be to largely increase the business of those insurance offices who take up this kind of risk. Every employer will, as a matter of prudence, insure his liability; the milliner who employs but one assistant and the shipbuilder who may employ thousands, will alike find it necessary to do so. At first sight it may appear that employers are having a fresh and harsh burden placed upon them, but a little reflection will show that this is not so. The risk of liability to pay compensation to an injured employé will be but another trade risk, like fire, bad debts, and the like, and will be covered by, in most trades, a small additional percentage on the present premium. Some employers and trades will, no doubt, feel the effects of the new Act. Thus, the tradesman, greedy of profits, who neglects fire insurance, sanitation, and who gets all he can "on the cheap," will find claims come upon him as a thief in the night; the employer who follows a dangerous trade will undoubtedly find his premiums of insurance largely increased. The Act, however, is good, in that it inculcates a wholesome prudence on the part of employers of every class, and it does something to alleviate the hard lot of many families who know that the sickness of or injury to the breadwinner means a bitter struggle with poverty. It should be explained that the Compensation for Injuries Law is wholly distinct from the Employers' Liability Law. By the former the employer has to give sustenance to an employé for injuries incurred by the latter, no matter under what circumstances, excepting wilful carelessness on the latter's part. By the latter the employé can only claim compensation for negligence on the part of the employer. Owing to that besetting sin on the part of our legislators—the absence of accurate definition in their Acts—the new law will undoubtedly be good—for lawyers, and much judicial interpretation will be needed before the "evident intention of the Legislature" is determined. Nevertheless the law is a necessary and welcome addition to the Statute Book.

BRITISH MOTOR-CARS IN FRANCE.

Much might be written on this head, but all may be condensed in a few words. British motor-cars in France are in the same category as the snakes in Ireland—there are none. We are not infrequently reminded by economists and others that there are not wanting signs to show that we have passed the zenith of British enterprise, and, instead of leading the way in new industries, we are following in the wake of others. Certainly there seems some foundation for this. When the abortive *Engineer* Competition was discussed, we were assured that manufacturers did not compete because they did not wish to "give themselves away" by publishing the details of their wonderful mechanisms; they were not ready, or "they had married a wife, and therefore could not come." The favourite objection was that the conditions as laid down by *The Engineer's* judges were too stringent, and demanded an unattainable degree of excellence. Well, granting all this, how is it that no English motors were to be seen at Paris-Dieppe or at Versailles—especially at the latter place? We have been assured with wearisome iteration: "Oh, we are not going in for light vans; we are designing and building vans for heavy traffic." And one hears mysterious hints how this firm has a heavy motor-van somewhere in its back-yard, and how that firm has another somewhere else; and one is begged to forbear mentioning any particulars of certain motor-vans that apparently are "Spanish castles." One can never get a sight at these remarkable productions. If ever there was a chance given to manufacturers and engineers to show what they could do, it was by the French at the recent competition. The conditions were absurdly simple and elastic; but as regards the Versailles Competition the trials were rigorously technical, and of a much more scientific character than those promoted by *The Engineer*, and yet not one single English firm competed. In a few years' time the motor-wagon industry will be, like locomotive building, in the hands of a few. Motor-wagons will be seen on the Indian, Chinese, and Argentine plains, but they won't be of British manufacture.

Apparently British motor-wagon builders are sitting on the fence and waiting to pick up wrinkles from their French rivals. If you ask a county councillor, a tramway director, or a manufacturer, the answer is invariably the same—"Oh, yes, we are studying the question and are *waiting* to see what the experience of the French is before adopting the motor-car," and so forth and so on. We can only say that our commercial position has not been attained by our fathers "waiting to see"; they did not wait, but went and did it. Considering the outcry that has been raised by manufacturers over *The Engineer* fiasco, we are bound to say that it does not redound to their character for enterprise that they refrained from appearing at the recent French competitions; and we would ask those who had entered for *The Engineer* competition, and who drew back at the last moment, why they have also neglected the French ones? Surely designs must now be pretty well worked out. We should regret very much if those merchants and others who are prepared to inaugurate road traction systems for heavy traffic, and who are waiting, not without signs of impatience, for the suitable kind of tractor, should decide to adopt a "Scotte" or "De Dion." It must be remembered that these motors have been thoroughly well tested and are known to suit the conditions which would obtain in many towns. Are they to be adopted because there is no suitable British tractor in the market?

THE FRENCH MOTOR-CAR COMPETITIONS.

"They manage these things better in France" is a somewhat stale observation, but one nevertheless true in many matters. It is certainly startlingly true as regards motor-car competitions. For the last few years these have become quite a national feature, and every summer several are held. At first they partook largely of the sporting element, but of late this has given place to a sincere desire to produce horseless vehicles that will have practical value. A curious thing about them is that they are projected mostly by newspaper proprietors, although it is not altogether apparent that the latter derive anything more substantial than the *kudos*. It cannot be questioned that these motor-car competitions are exceedingly popular with all classes of the community. The rich find in them a new excitement distinctly more intellectual than that attaching to horse-racing and other equine pursuits; the middle classes hail the possibility of "having one's own carriage" without the expense of a horse; while shopkeepers and tradesmen welcome them as solving the problem of cheap traction and better internal transport. The interest that is thus taken in motor-cars is of an intelligent nature, and a competition gives an excuse for one of those fêtes which our French friends manage so well. Both the Paris-Dieppe and the Versailles Competitions have been eminently successful. The light oil-motors have been proved to be safe, reliable, controllable, and ridiculously cheap in working. In the hands of ordinary French workmen they give no trouble. Indeed, many of these motor-carriages are looked after and driven by page-boys. The success attained by these motors at Dieppe has, we confess, compelled us to modify some previously-entertained opinions. Like most people in England, our ideas of mechanism have been largely the result of association. When one is accustomed to move about among engines that put anything over 1,000 H.P. on to a single crank, one is apt to regard lighter mechanism with something like good-natured indifference. Hence the man who squeezes up an armour-plate or who drives an express engine, will regard an oil-motor that can be comfortably enclosed in a hat box as an interesting toy, but wholly incapable of serious and practical work. It is these very natural but prevalent ideas that we think account for the unquestionable suspicion with which motor-cars are regarded in this country; the average man cannot grasp the fact that so much power can be produced in so small a compass. Added to this there is the so-called risk attaching to the use of the lighter petroleum oils—a risk which exists, and will exist, because in our Board Schools we teach boys and girls such things as pianoforte playing and shorthand rather than the elementary physics connected with kitchen boilers and petroleum lamps. The writer may be permitted to mention in this connection that a few years ago, when the "deadly lamp" agitation was rather acute, he offered the London School Board to give a course of elementary lectures on the

A HEAVY BRONZE TAIL SHAFT.

contains over 100 pages of information. Price 6d.; post free, 7*d*., of Messrs. F. King and Co., 62, St. Martin's Lane, London, W.C. See it for the Regulations respecting Automotor-Carriages and the Carriage of Petroleum.

and is hardly what one would expect from an ex-Minister of the Crown. Liverpool has an exceptionally able municipal engineering staff, and is also a large railway centre. Surely it should not be difficult to find a suitable tramway engineer?

FIG. 1.—PEUGEOT MOTOR (General View).

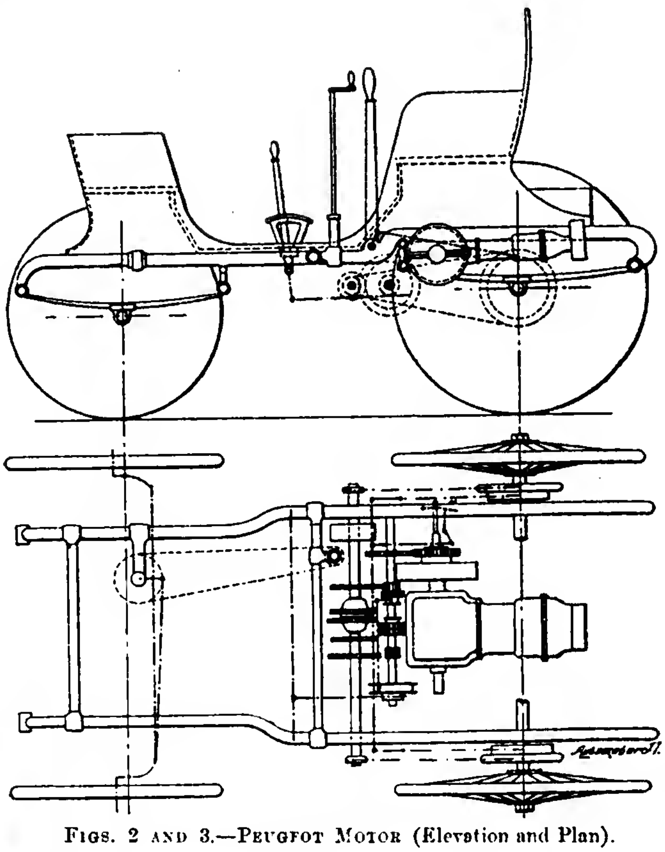
motors, they are absolutely safe, and are really wonderful examples of large power being obtained from very small and light machines. Among those who have worked hard in the development of the light oil-motor the name of M. Peugeot stands deservedly high. His motor-cars and motor-cycles are well known, and he has obtained many successes with them. Lately he has made a new design of motor which we illustrate in the accompanying drawings. It will be seen that the new motor (Fig. 1) is horizontal and has two cylinders, the casings and guider of which terminate in a cylindrical chamber, thus enclosing the cranks and admitting of very perfect lubrication. The rear part of the cylinders forms another chamber in which are the valves, &c.

The inlet valves are above and the exhaust valves below. For inspection purposes the valve chamber is fitted with a removable cover. Behind the valve box, as will be seen, is the ignition chamber containing the ignition tubes, which are heated by means of a lamp.

Figs. 2 and 3 are respectively an elevation and plan of the latest type of Peugeot car, and show the arrangement of the motor and gearing. Figs. 4 and 5 are respectively vertical and horizontal sections through the motor. It will be seen that the motor works on the Otto cycle, and that by the use of the two cylinders there is an impulse at every revolution. Attached to the end of the motor-shaft is a heavy-coned fly wheel into which fits a friction cone for transmitting the motion through the gearing. On the other end of the motor-shaft is a crank handle used to draw in and compress the initial charge of oil and oil vapour. Fig. 6 is a centrifugal governor, and Fig. 7 an expansion cam.

The admission and exhaust valves are actuated by a shaft which is placed underneath the motor. At the front end where it enters the cylindrical box, it carries a lever which is made with a slide at the upper end. This slide, K, engages in the groove of the cam, C, of which a side view is given in Fig. 7. An angular movement is imparted to it by this arrangement, giving to the distributing shaft a partial rotation. This oscilla-

with the reduced movement of



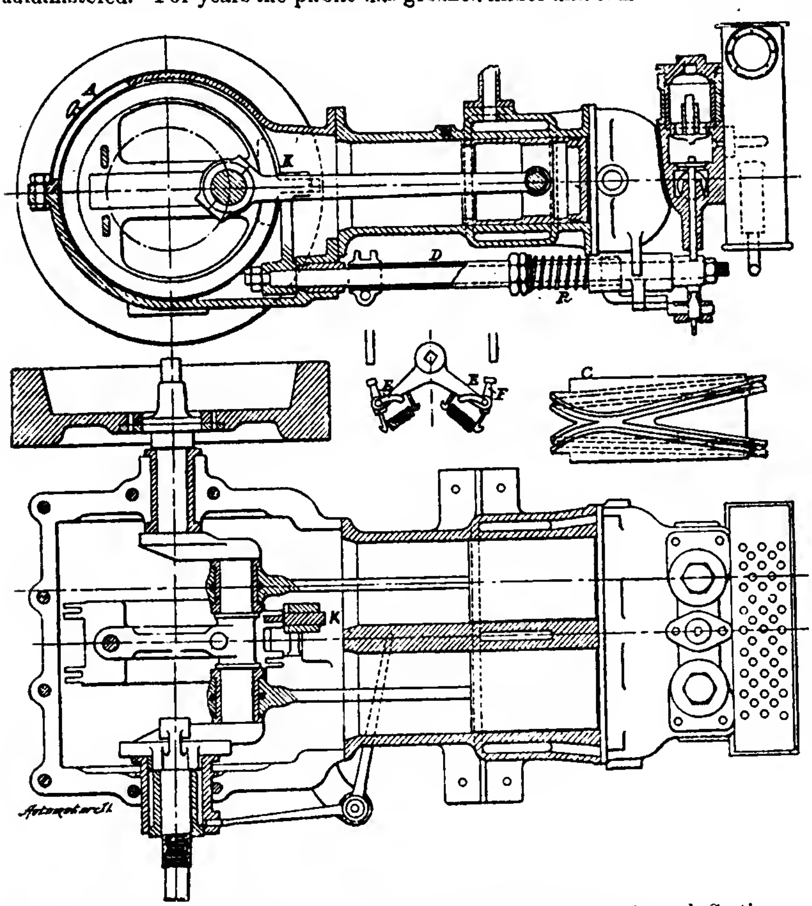
FIGS. 2 AND 3.—PEUGEOT MOTOR (Elevation and Plan).

the governor all the various parts resume their normal positions.

From the trials that have been made this motor gives very great satisfaction and is remarkably free from vibration.

POST OFFICE ANOMALIES.

The great test of the efficiency of public administration is satisfaction on the part of the public, and contentment in the rank and file of the service. Judged by this standard the British Post Office cannot by any means be said to be well administered. For years the public has groaned under and complained of official inefficiency, and for years the postal service has been characterised by seething discontent and agitation; the public is badly served, and the minor Post Office official badly treated, till at length we see the latter in almost open revolt. We do not intend here to discuss the grievances of the Post Office officials, but we may say that when we see a body of skilled and, therefore, intelligent public servants obliged to resort to the most extreme measures in order to obtain redress for admitted wrongs and abuses we can only conclude that the administration under which they serve must be badly managed. It is a safe general conclusion, and one fully confirmed by all history, ancient and modern, that dissatisfaction in subordinates is, as a rule, due to incompetency on the part of the superiors. In the army and navy scores of cases can be cited in which the gravest consequences to the public service have been averted by the simple expedient of removing the officers. We do not say that the Post Office is another case in point, but speaking from some



Figs. 4, 5, 6, and 7.—Peugeot Motor (Vertical and Horizontal Sections, Centrifrugal Governor, and Expansion Cam).

experience of its ways and methods, we cannot say that the Post Office administration strikes us as particularly successful or economical. The public pays a very high price for, after all, a very inferior service. The public does not get value for its money, nor are its interests sufficiently safeguarded. Unfortunately the British public is deplorably apathetic in looking after its conveniences. It is a generous employer who does not like to deal harshly with its servants. Thus, because the Post Office wills it, London, the metropolis of the world, is practically without a telegraphic or postal service on Sundays, and it is theoretically unlawful to purchase a postage-stamp after 8 p.m. on week days. On the other hand the public is robbed of many thousands of pounds annually because valuable letters have to pass through the hands of badly-paid minor officials who have little incentive to honesty. London, and for that matter, the large provincial cities, enjoy the worst and most expensive telephone service that prevails in any civilised country, merely because of the lack of business capacity on the part of the higher Post Office officials who have managed so badly that the public suffers under a telephone monopoly. Some day this grievous mistake on the part of the Post Office will be rectified by public money being spent in buying back public rights.

Consider also the difficulties that the Post Office has made in the matter of district messengers. A public convenience cannot be utilised to its full extent because of the difficulties made and obstacles put in the way by the Post Office officials.

A Directory of Telegraphic Addresses is surely another public convenience, yet the Post Office would neither issue one officially nor allow any private person to engage in the work. It at last dawned upon the somewhat pachydermatous brain of the "high official" that its attitude was ludicrously absurd, not to say improper, and official opposition was at length grudgingly withdrawn, and the public now has a convenience it should have had twenty years ago.

Similarly in the Engineering branch of the Post Office one sees but little evidence of acquaintance with the latest advances in telegraphy. Although it has been pottering at the subject for years and spending thousands of pounds in absolutely futile "experiments" (*sic*), the Post Office cannot successfully join up the coast lightships with the shore telegraph system; and when the next Post Office Estimates are submitted to Parliament the British public will be asked to pay a heavy royalty to an Italian electrician, who has succeeded in accomplishing what our Post Office engineers are paid to effect, but seemingly cannot, or, at any rate, have not so far. While on this subject we would draw attention to what we consider a very grave Post Office anomaly, and one which makes a most objectionable precedent. The engineer-in-chief of the Post Office draws a very large salary from the public, and at the same time carries on a very large private practice as a consulting electrical engineer. We believe there is no parallel instance to this in the whole public service. What would the public say if the Admiralty, for instance, permitted the Chief Constructor of the Navy to design privately battleships for foreign powers; or what firm would pay a servant a high salary and permit him to carry on a business of the same kind?

It would not be difficult to point out anomalies in every branch of the postal service—it simply bristles with them.

Perhaps some of the most ludicrous of these anomalies are to be found in the Regulations governing the transmission of letters and newspapers through the post. It is difficult, indeed, to say on what principle of public policy or common-sense it has been attempted to follow in framing these Regulations. By them a prepaid postage of one halfpenny is charged for the inland transmission of any daily or weekly registered newspaper, *the weight being disregarded* (*sic*). Now newspapers are commercial articles manufactured for profit. They owe their bulk and weight to the large proportion of advertising matter; and the question at once arises, Why should the Post Office act practically as a free carrier and distributor for newspaper proprietors and not for other tradesmen? At present a newspaper, if published daily or weekly, and not exceeding 14 lbs. in weight, can be sent to any part of the United Kingdom for one halfpenny, yet it costs three pence to send a pound of tea or a pound of hair pins through the post. Why should the grocer and ironmonger be discriminated against in favour of the other tradesman, the newspaper-monger? Again, inasmuch as weight cannot be moved without an expenditure of energy, and as energy costs money, and inasmuch as 14 lbs. of newspaper are moved for ·5*d.* and 1 lb. of tea or other produce is moved for 3*d.*, the question arises, Why should it cost 84 times as much to move a pound of tea as to move a pound of newspaper? As a matter of fact, from the carrier's point of view, the freight on both should be about the same, as both are easily damaged. Who, then, pays the difference in the freight charges made by the Post Office? Why the ordinary taxpayer.

It is contended that the State should encourage the cheap transit of newspapers because of the educational value; when we hear this respectable fiction we do smile. Of what does the ordinary daily nowspaper consist? Excluding two or three, not more, daily papers which have some undoubted educational value and literary merit, the ordinary "daily" consists of 75 per cent. of advertising matter, the balance is made up of such intellectual pabulum as racing, betting, cricket, football, and other sporting intelligence, Police Court news, feeble party political leaders and reviews, pompously designated as "literature"; the rest is "gush and gossip." Why the ordinary taxpayer should be mulcted in order to disseminate tons of such stuff all over the country passes our comprehension. Let us just glance at the heavy weeklies. In the following table we give the proportions of advertising and literary matter as contained in some of them:—

Table showing proportions of Literary and Advertising Matter, Total Weights, and Cost of Postage of some Weekly Newspapers.

Name of Paper.	Weight of Literary Matter.	Weight of Advertising Matter.	Total Weight.	Cost of Postage in United Kingdom.	Cost of Postage, Foreign.
	oz.	oz.	oz.	d.	d.
Engineering ...	4¼	10¾	15	½	4
Engineer	4¼	9¾	14	½	3½
Queen	11	6¾	17¾	½	4½
Field	9½	9	18½	½	5
Lancet	5¾	5¾	11½	½	3

It will be seen that the class of journal ranges from the shallow and frivolous *Queen* to the dignified and classical *Lancet*, and includes our professioual contemporaries, the engineering papers. In all these weeklies the percentage of advertising matter is very high; on the other hand so, excepting the organs of femiuism, is their literary and educational value. From the latter point of view it cannot be questioned that the advertising pages alone of the two senior engineering papers are infinitely more instructive to an intelligent boy than a score of daily papers. Let us labour this point further. Assuming that the reason why the State undertakes the dissemination of newspapers at a ridiculously cheap rate is the "educational and elevating (*sic*) advantages of a free Press," let us see how the Post Office treats that section of the Press which is published monthly. The majority of these periodicals are distinctly educational in their various ways, and hence should at least be treated on the same footing as the dailies or weeklies. Yet the Post Office carries them at the rate of 4*d.* per lb., or ·25*d.* per ounce. Since 14 lbs. of newspaper can be carried for one halfpenny, it is seen that the cost of carrying 1 lb. of monthly periodical is 112 times as much; the effect of this is to seriously hinder the circulation of at least those monthly papers which appeal to a limited and select class of the community—the heavy postage constituting a serious tax. In other words, the Post Office aids by all means in its power the dissemination of the least useful, and in many cases a very pernicious, kind of literature, and heavily taxes that which is most worthy of encouragement. Referring to the heavy weeklies again, it may be remarked that taking their weight as approximately 1 lb. they are carried for one halfpenny; were they published monthly the cost of postage would be 4*d.*, or eight times as much. This anomaly is after all entirely characteristic of Post Office ways and methods.

Lastly, we have that other anomaly arising out of the former. As we have seen, a discrimination is made in favour of daily and weekly papers as against monthlies for inland postage. For foreign and colonial postage a uniform rate of 4*d.* per lb. is charged for all. Thus to send a heavy weekly weighing 1 lb. to the North of Scotland, a distance of over 600 miles, costs only one halfpenny, but to send the AUTOMOTOR, which weighs but 6 oz., thither, costs 1½*d.* To send the same weekly to Paris will cost 4*d.*, while the charge in the case of the AUTOMOTOR is, as before, 1½*d.*

These anomalies cannot be explained by any principles of equity that we know of. We rather think that they are due to the existence of a vicious system of selection and promotion which obtains in the higher branches of the service.

The transmission of letters, telegraphic messages, and general intelligence is a special business *sui generis*, requiring a long technical training to manage properly. Yet it will be found that the higher officials of the G.P.O. are, in the many cases, without the necessary qualifications. Too frequently they owe their positions to political patronage and influence, and there are scores of men in the service drawing salaries of £500 and upwards who intellectually are in no way superior to the "lady operator," who draws a modest stipend of £60 per annum. Many ways of effecting Post Office reform are from time to time suggested in the public Press, and these range from the infliction of boiling oil *à la Mikado* upon the higher officials to their condemnation to serve as "sorters," and from entrusting the administration to those clever persons who organise successful bank robberies to placing the whole concern in the hands of a private commercial company to be run on commercial lines. We certainly are not disposed to deal Japanesely with the "higher officials," and we are not sure that the other methods have not some disadvantages attaching to them respectively. Our suggestion is, that the supply of "small crosses and orders for Mayors and Recorders" and Post Office officials should, as regards the latter, be entirely stopped until a fair amount of efficiency had been attained in the service, and the many existing anomalies removed. The "higher officials" might, in the meanwhile, be compelled to read in their own time a selected variety of those low-class papers which at present they carry hundreds of miles for a halfpenny, and be strictly debarred from reading any monthly periodical that pays more than that for postage. A few weeks of this treatment would, we think, induce a more wholesome and less "official" frame of mind. Till reform be effected, we, slightly altering the text, shall be inclined to say of the Post Office, in the immortal words of Schopenhauer:—"Incompetency sits in high plsces and folly has the casting vote."

Heavy Motor-Car Trials.—From Paris our Correspondent writes that it has been definitely decided to hold a heavy motor-car competition during October, 1898, under the same conditions as those obtaining under the recent trials at Versailles. English manufacturers will then have another opportunity, and no excuse can be made on the score of insufficient notice or time.

Hon. Local Secretary	E. SHRAPNELL SMITH, Esq.
Semi-Official Journal of the Association	THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SELF-PROPELLED TRAFFIC ASSOCIATION.

LIVERPOOL AND DISTRICT CENTRE.

BY invitation of Mr. Alfred L. Jones (vice-president), a deputation of the council of the Liverpool centre of the Self-Propelled Traffic Association went to Paris to attend the recent trials of heavy motor vehicles, organised by the Automobile Club de France. The deputation appointed included Messrs. Alfred L. Jones, Everard R. Calthrop, S. B. Cottrell, Henry H. West, Lawrence Jones (hon. solicitor), and E. Shrapnell Smith (hon. local secretary). Various pressing business engagements, however, kept back four of the party at the last minute, Mr. West and Mr. Shrapnell Smith therefore being left to report results to the council. The chief object in view has been to learn the exact position of affairs on the Continent before the Association makes any public announcement relative to the proposed exhibition and trials, to be held in Liverpool about June next.

MOTOR-CARS AT THE AGRICULTURAL HALL, ISLINGTON.

AT the Laundry and Motor-Car Exhibition, under the management of Messrs. Cordingley and Co., to be held at the Agricultural Hall, from August 23rd to September 4th, there will be, we understand, a few motor-cars for the inspection of visitors. Amongst those who may be represented are the Anglo-French Motor-Carriage Company, with two or three vehicles, probably including one of their four-seated Victorias driven by a Petrol motor, a four-seated barouche fitted with improved double-cylinder motor and frictional spur gearing, and a four-seated dog-cart; Messrs. New and Mayne; The London Electrical Cab Company; English Motor-Car Company; and Martin's Motor Company. There will also be a steam carriage on the Serpollet system on view. In our next issue we shall give all necessary particulars of novelties, &c., which may be exhibited.

NOTES OF THE MONTH.

Recently an advertisement appeared in our columns offering £100 for steam tractor drawings. In spite of all the statements flying around about the collapse of the motor-car boom, &c., the advertiser received so many replies that he has been constrained to issue a printed letter to applicants, supplying the following details and raising queries preparatory to making a selection from those ready to supply drawings :—

"My carriage is an ordinary landau, weighing 10½ cwt. empty, and, when loaded, is easily drawn on an ordinary road by a pair of 15·1 cobs, at an average speed of 9 miles per hour. I have the desire to make and substitute for the horses a tractor as described in the advertisement, the carriage not to be materially altered, and I beg to ask you :—

"1. Are you aware of such tractors having ever been used?
"2. If so, please name them.
"3. Which of these do you consider the best?
"4. Could you improve upon it?
"5. Are you intimately acquainted with flashing boilers?
"6. If so, please name them.
"7. Which of these do you consider the best?
"8. Could you improve upon it?
"9. Can you provide for smokelessness?
"10. Can you provide for invisible exhaust?
"11. Could all your materials be easily procured, such, for instance, as the boiler tubes?"

A paragraph has recently been going the round of the Press stating that while a motor-car belonging to a Coventry firm was proceeding from London to Leeds, the driver, when two miles from Hatfield, found himself suddenly confronted with a cyclist. He caused the car to swerve, and it overturned into a ditch. The three occupants were thrown out on to the road, and sustained some injury. We have made every enquiry, and can find no authentic corroboration of this statement, either in Coventry or elsewhere. It is curious how these wonderful things happen, and nobody beyond the journalist upon the spot knows anything about them.

A motor-car was this year introduced into the Dunmow Flitch ceremonies after the "sentence" had been passed, the judge and jury parading through the field and along the village in a large motor-car.

Messrs. Windover, of Huntingdon, ran a motor-car, made by their own workmen, over to Peterborough the other day. It carried four passengers, the car itself weighed only 6½ cwt., ordinary crude petroleum being used. The journey to Peterborough and back consumed about 1½ gallons, the journey of 40 miles therefore costing about 6*d*.

The first license for a motor-car to ply for hire in Portsmouth was last month issued to Mr. Rose, of Great Southsea Street. When the application for the license was first made the General Purposes Committee did not know quite how to deal with it, as they were not certain whether the car should be classed as a hackney carriage or a traction engine. The difficulty was, however, ultimately got over, and a hackney carriage license was issued for the vehicle.

A race between a motor-bicycle and a safety pedalled in the ordinary way was decided at Coventry on August 3rd. W. J. Stocks, on the safety, which suffered two punctures, covered 27 miles 300 yards in an hour. The motor-bicycle ran splendidly throughout, keeping up a steady, even pace that would have daunted a less experienced and less capably paced man than Stocks. Soon after the start the motor slowed down, and the crowd jeered immensely, for they imagined its end had come. The cause of the pulling up, however, was that the rider thought, by the shouting of a section of the crowd, that some mishap had occurred on the track, and he requested they might be kept quiet. If Stocks is to be complimented upon his performance, then Taylor deserves also a word of praise for his steering and control of the motor. Although the motor was 300 yards behind, he would be a bold man who declared that the cycle will always be able to beat the motor.

Though the motor-car makes little headway in England, there is every prospect of its services being utilised in Westralia. Already the bicycle is much used on the goldfields, where it has proved to be invaluable; and now the motor-car is being discussed as a solution of the transit difficulty in many parts where the sandy plains form a good road, but where lack of water makes travelling difficult for beasts of burden. It is thought that the camel will be easily superseded by his pneumatic-tyred rival.

Motor cars, built in Hamilton, are running daily on the popular coaching routes in the Island of Bute.

At the Agricultural Society's Show at Harrogate last month, the Yorkshire Motor-Car Company (Limited), of Bradford, showed specimens of the sociable motor-car—capable of maintaining an average of 10 miles an hour on level ground and of making 4 miles an hour up hills, of the Bollée motor-tandem, and of the Beeston motor-tricycle.

On the last day of July Mr. Balfour rode from Downing Street to the House of Commons on a motor-car, on which was also Mr. A. F. Jeffreys, M.P. The start from Downing Street was witnessed by Mr. Chaplin, Sir W. Walrond, and other members of the Government.

One of the most popular pictures now being shown at the Palace Theatre on the American Biograph is "a motor fire-engine." Mr. Charles Morton is always up-to-date in everything he introduces.

We are glad to see that the daily Press is at length realising the importance of the motor-car. Thus the *Daily News*, in its issue of July 26th, contains nearly half a column of an account of the Paris-Dieppe contest, and even devotes an editorial paragraph to it. Says our contemporary :—"Two points are worthy of note with regard to the motor-car race on Saturday from Paris to Dieppe. The first is, that of the fifty-nine competing vehicles none were driven by electricity; the second, that the only steam-driven carriage, which carried as many as four persons, came in next to the winner. All the others were of the somewhat evil-smelling oil type, and the winner travelled at about the usual rate of a Continental railway train—namely, 22 miles an hour. Indeed, the guests who witnessed the start, and were dispatched in a first-class special train to Dieppe, arrived too late to see the winner and several others come in. To many who place more faith in the so-to-say old-fashioned method of steam propulsion, the performance of the Comte de Dion's brake ought to be an incentive to the attainment of greater perfection in its use on the road."

A motor shareholder writes to the *Birmingham Daily Gazette* and says that when at the Imperial Institute in London last year, he saw several makes of motor-cars and motor-cycles, and one of the latter (said to be driven by the Pennington motor power) was quoted as having done a mile in 58 seconds, or at that rate. He asks whether a motor-cycle has ever been ridden by a man at such a furious pace, and, if so, for what distance? We have no record of a motor-cycle having attained anything like this speed on the level. Thirty miles per hour is, we believe, the utmost that has yet been attained for a short spurt.

THE Locomotives on Highways Bill has now a fair chance of becoming law. It deals with heavy traction-engines, and while removing the vexatious nature of the present restrictions, gives improved powers to local authorities. It was originally drawn on the recommendations of last year's Select Committee, but was not drafted until this Session was well advanced, and is in charge of Mr. Griffith Boscawen, who succeeded in getting it read a second time, just before Whitsuntide, as an unopposed measure. The Bill has been before the Standing Committee on Trade, and after a long discussion and some opposition was passed.

THE Yeovil Motor-Car and Cycle Company wish it to be known that they do not use mineral spirit in their motors, but only ordinary petroleum.

THE following specimen of bucolic wit is amusing in its way. A scribe on the *Bedfordshire Times*, who evidently is trying to become proficient in writing what are known as "newsy" (horrid word) "pars" thus delivers himself:—"The gods preserve us from the motor-car when it is of the oleaginous variety. One came cantering along High Street at twenty minutes past seven on Saturday evening, and literally filled the street with its pungent effluvium, which lingered long and lovingly in the air. But what must it have been to be there—that is to say—on the car!" Note the exact time, and the exquisite alliteration in "lingered long and lovingly." This gem of provincial journalism is distinctly precious.

REFERRING to the recent conflagration at the I.E.S. Accumulator Works, the *Surrey Advertiser* says:—"It was nothing short of providential that a number of dynamos stored in the building failed to explode, otherwise the damage to surrounding property would probably have been enormous." And this is probably the type of writer put on to enlighten the British public as to the technicalities and future of motor-cars!

THE Pneumatic Brake Company (Limited), of Manchester, have introduced a pneumatic brake of simple design and specially suitable for motor-cars. It consists of an air-pressure pump, underneath the boot of the coach, connected by a copper tube to a brake on the wheel. The brake is operated by pressing the foot upon a lever attached to the pump, and the air from the pump rushes through the tube, and is forced into a pad fitted on the brake. The inflation of this pad forces a rubber block—which is fitted in an iron shoe—on to the wheel. The arrangement can be fitted either to pneumatic or iron-tyred wheels, and no matter what weight is in the carriage it is claimed that it does not alter its position.

THE Beeston Pneumatic Tyre Company have brought out a new tyre for motor-cars and other road vehicles. It is the invention of Mr. Beebe, of Ohio, and is built up by alternate layers of rubber, canvas, and crimped steel spring piano wire in enough layers to make it puncture-proof.

ANOTHER motor-car wedding procession has just taken place, this time at the Kentish village of East Peckham. The bridegroom, Mr. Joseph Taylor, is connected with the Branbridge Motor-Car Factory, and the bride, Miss Annie Rhodes, of Collier Street, is an enthusiast for these vehicles. The happy couple, together with a number of relatives and friends, were conveyed from the bride's residence to the church by a traction engine, to which were attached several trucks, all effectively decorated with flags, flowers, and evergreens. The road was lined with persons anxious to catch a glimpse of the extraordinary "turn-out." After the wedding service the newly-married couple and their friends resumed their seats in the trucks and were conveyed to the Branbridge Mills, several motor-cars joining in the procession. On their arrival the party and their novel means of conveyance were photographed. Subsequently the locomotive, with its trucks, followed by the motor-cars, proceeded to the village of Collier Street, where the wedding breakfast was served in the open air.

MOTOR-CAR excursions are now a regular feature of Blackpool. The innovation has proved immensely popular, the cars being loaded up to their fullest capacity every trip. Llandudno intends following the example of the Lancashire watering-place as soon as some motor-cars can be obtained.

AT a recent meeting of the Special Tramways Committee of the Liverpool Corporation, Sir A. B. Forwood in the chair, a proposal to elect Mr. Pearson as engineer for the new electric tramway was defeated by seven votes to five. Sir A. Forwood then resigned the chairmanship of the committee, and the further consideration of the engineership was deferred. Mr. Pearson is an American, and the feeling of the majority was that the work could be done by an English engineer or some one of the Corporation's own staff.

WITHIN the past few days a piece of land situated between Tor Railway Station and Shiphay Bridge, Torquay, has been purchased for the erection of a building, in which works are to be carried on for the manufacture of motor-cars, according to the invention of Dr. Frank Briggs, of Torquay. Possession of the property was taken on August 11th, and plant will be laid down to the value of about £2,000.

THOSE POOR BRITISHERS!

A LARGE manufacturer of cycles having works at Cleveland, Ohio, says in an American contemporary:—"It is impossible for other countries to equal American goods until they have the means and the men. By the means I mean automatic machinery. America leads the world in these devices. Automatic machinery may be bought, but unless men know how to operate it good results cannot be obtained. Germany comes nearer using automatic machinery according to the American ideas than any other country. England uses comparatively few automatic tools, most of the labour being done by hand. In the last six months, however, the makers of automatic tools in America have been rushed to death with demands made on them by English cycle manufacturers, all of whom are anxious now to get in automatic machinery. The American cycle manufacturers have done more for American export business than any other one class of men since the foundation of the Republic. The world for years has been thinking that Americans were the finest mechanics on the globe. It was largely a theory; the aggressive American cycle makers have now made it a fact, as there is not a civilised country in either hemisphere in which at least a half-dozen American made wheels are not well and favourably known. The finish, the construction, the mechanical nicety and strength, as well as proportions, verify the opinions of all people, that American mechanics have no equal." We do smile.

DOINGS OF PUBLIC COMPANIES.

Mr. G. R. Blot announces that his French house has been formed into a limited company, to be known as the Compagnie des Accumulateurs Electriques Blot, with a capital of 1.600,000 francs. The offices will be situated at 39, *bis* Rue de Châteaudun, Paris. The directors are M. Jules Offroy, M. Octave Chemin, M. Henri Ehrmann, M. Henri Hénon, M. Charles Meyer, and M. Georges-René Blot.

On the 6th inst. a meeting of the directors of the new Pennington Motor-Car and Cycle Company was held at the offices, 10, Leinster Street, Dublin. Alderman Meade presided, and the principal promoter of the Company, Mr. Pennington, who had returned to Dublin after an absence of some weeks on business in the United States, was present. Matters of importance in connection with the Company were discussed, and all the arrangements not being completed, another meeting was held on the 12th inst., when, says the *Irish Field*, the directors passed a resolution convening an extraordinary general meeting of the shareholders for Monday, August 23rd. We fear that there is nothing for the directors but to propose the voluntary liquidation of the Company, and the return of the money to the shareholders. The reason is, we believe, that the directors cannot see their way to complete with the promoters until they are satisfied that all statements are in fact as they were set forth in the prospectus. Had everything been carried through as originally arranged, this Company would no doubt have enjoyed a successful future, and would not only have resulted in the employment of much Irish labour in what will undoubtedly be one of the great industries of the future, but also would have resulted in large profits to those holding shares in the undertaking. No blame can be attached to the directors by any reasonable man, as they did everything that could be done to safeguard the interests of those who entrusted their money to them, and now that they find difficulties are placed in their way by the promoters, they have at once decided to place full information of the position before their shareholders, who can resolve, if they wish, to have back their money, less expenses incurred by the Company. This course is the only course expected from a board of directors composed of men like those responsible for the proper administration of the affairs of this Company, and we congratulate them upon their prompt methods. In the meantime we understand, as a precaution, a committee of shareholders has been formed to protect their mutual interests, with offices at 22, Blessington Street, Dublin.

Mr. P. W. Northey has been appointed receiver and manager of the Epstein Electric Accumulator Company (Limited), with a view to reconstruction.

Arrangements have been made to invite all the shareholders of the London Electrical Cab Company, as well as a large number of representative gentlemen unconnected with the Company, to a meeting at the Company's premises in Juxon Street, Lambeth, on Thursday next, the 19th inst., for the purpose of showing them what progress has been made, and to inaugurate the Company's business as electrical cab proprietors. As a start, the Company already have a couple of cabs about London, the new vehicle being very smart in appearance, and constructed somewhat in the style of the ordinary four-wheeler. On Friday last one of these cabs was driven to the Kennington Lane police-station, where it was inspected by one of the public carriage inspectors (Sergeant Howell), and duly passed as being fit to ply for hire in the streets.

The decision recently given in favour of the Ixion tyre patents is of far-reaching importance, and should undoubtedly tend to lower prices all round. It will depend upon the future action of the directors as to what extent. Several of the shareholders in the meantime appear to be dissatisfied with the *laissez faire* attitude which the directors have, so far, taken up. One correspondent points out that "the directors of the Ixion Company have now got it in their hands to knock the Dunlop monopoly entirely out of the market by cutting prices to the extent of 50 per cent., and supplying at a figure which leaves them a good profit. It is quite evident that where the Ixion, with a capital of 100,000 shares, can do business, the Dunlop Company, with a millstone of £5,000,000 round its neck, cannot follow." Whilst another, in speaking of the far-reaching effects of the decision, states that the tyre trade in this country has been a practical monopoly—the monopoly of the long purse; but patents expire, as did that of R. H. Thomson, C.E., in 1845, for a pneumatic tyre. The cycling public in this country, under the beneficent rule of this monopoly, pay, roughly speaking, 55*s.* for tyres which can be purchased of the same quality, or better, in America for 29*s.*, and on the Continent for 25*s.*, and presumably the American and Continental manufacturers sell at a profit, so that monopoly in this country reaps, over and above the ordinary traders' profit, an additional bonus of 30*s.* per pair on tyres sold. A vacuum is not more abhorrent to Nature than a monopoly to the British trader, and in due course a way round will be found, and then inflated profits on the above basis will come down with a Humpty-Dumpty sort of slump—and the success of the Ixion Company in the law courts may be the first sign of the coming storm. As the Ixion tyre, we understand, is particularly suitable for motor-cars, we hope the directors will not be slow to follow up their advantage by making some money for the Company, and thereby fulfil the "obligations they owe to the shareholders and themselves."

In view of this decision and probable competition, the new "Amalgamated Pneumatic Tyre Companies (Limited)," with a capital of £1,300,000, is a fairly strong order—especially when it is remembered that there are several other tyre-making companies, not included in the amalgamation, which hold licences from the Dunlop Company. This amalgamation is, therefore, not at all likely to stop competition, and it is significant the way in which this fact is steered round in the prospectus, the exact words being: "Undue competition and cutting of prices between the various tyre businesses amalgamated will cease." Considering that the cycle trade is on the wane, and bearing in mind the above points, we would suggest to our readers the wisdom of leaving the shares to be taken by the companies amalgamated in payment for their monopoly (?).

We understand that the shareholders of the Lamina Accumulator (Elieson's Patents) Syndicate (Limited), have decided to wind up the concern by voluntary liquidation, and have appointed Mr. T. Featherstone Smith, of 28, Basinghall Street, liquidator. Arrangements have already been entered into for the sale of the business to a larger company to develop it on an extended scale. We hear that the capital is privately subscribed, so that there will be no public issue.

New Brotherton Tube Company.—The statutory meeting of shareholders in the New Brotherton Tube Company was held on July 26th, at Wolverhampton. Mr. E. Lisle (Chairman of the board of directors) presided. The Chairman said it was not usual on the occasions of statutory meetings to say much more than was necessary to create a certain amount of confidence amongst those shareholders who had invested their money in the Company. He might say that the whole of the capital of the Company had been fully subscribed and all the shares allotted. The directors alone and their friends had taken up quite one-half the capital of the Company. He might say that he, himself, personally had invested between £5,000 and £6,000 in the Company, and other members of the board had also taken up shares to heavy amounts, and, like himself, were all large users of tubes. He did not agree with the critics, that they were likely to have a very bad time of it in connection with the tube trade in the future. He believed, on the other hand, they were going to have as good a year this next year as they had last. As regarded machinery, theirs was a very young house in the bicycle-tube making, but they had got, he should think, the latest machinery any works could have. The over-supply of tubes to-day, which was apparent, would not be so much felt because there was a trade springing up that would take many steel tubes; that was the motor-car industry. Motors, instead of being built with wood on the old carriage principle, would be built with weldless steel tubes, and they could look forward for a very big trade for tubes in the construction of motor-cars. Their Company was making a lot of tubes to-day for motors. A vote of thanks to the Chairman brought the proceedings to a close.

New Issues.

For the Month ending August 14th.

New General Traction Company.—Issue by the Railway Share Trust and Agency Company, 4, Bank Buildings, E.C., of 20,000 6 per cent. cumulative preference shares of £5 each in the New General Traction Company (Limited), at the price of £5 2s. per share. The prospectus states that those are the unissued portion of the existing preference share capital, the Company having a total share capital of £270,000—£150,000 in preference, and £120,000 in ordinary. The company was formed in March, 1896, for the purpose of installing systems of traction for light and street railways, tramways, &c., either by applying electric or other power to existing systems, or by assisting in the promotion of new schemes. The Company has already introduced electric power to tramways at Coventry and in the Isle of Man, and other schemes are awaiting Parliamentary sanction. To assist in carrying out these works, and to deal with other offers which are being made to the Company, the present issue of capital is required.

Blackpool Motor-Car Company (Limited).—Share capital £25,000, in ordinary shares of £1 each. The Company is formed for the purpose of engaging in the business of motor-car proprietors, running and letting out for hire motor-cars for pleasure and trade purposes throughout the United Kingdom, and to acquire as a going concern the business of the Blackpool Motor-Car Company (Limited). as from May 19th, 1897. In regard to the matter of profits the directors estimate, on the basis of 40 cars running, a total annual profit of £8,000 should be secured, enabling a dividend to be paid of 25 per cent. of the entire capital of the Company, and leaving a balance of £1,650. The Company proposes to chiefly use the Daimler oil-motor. Although Blackpool is selected for the commencement of the operations of the Company, the directors intend to establish branches in popular country and seaside resorts, including Brighton, Bournemouth, Harrogate, Southport, &c.; and it is also intended to undertake the conveyance of farm produce to the markets, and, in fact, do the work for which light railways were intended, and at a fraction of the cost. The purchase price for the whole of the vendors' plant, including six motor-cars, stock-in-trade, tools, goodwill, &c., and the benefit of a contract with Messrs. J. and C. Stirling, motor-car builders, Hamilton, N.B., for the supply of 40 motor-cars specially adapted for the Company's business, on exceptionally favourable terms, is £5,000, payable as to £2,000 in cash, and as to £3,000 in fully-paid shares of the new Company. The offices of the Company are The Kiosk, Talbot Square, Blackpool.

National Motor-Carriage Syndicate (Limited).—Share capital £30,000, the present issue being 12,000 shares of £1 at par. The objects of the Company are to acquire for traction and motor-carriage purposes the entire rights of the United Kingdom in the storage battery employed by the Sussmann Electric Miners' Lamp Company (Limited) for their portable electric miners' lamp. Also certain inventions of Mr. H. F. Joel, A.M.I.C.E., consisting of an electromotor of high efficiency, specially designed for the propulsion of vehicles, and a new and improved gear for transmitting the power, for which inventions four patents for the United Kingdom have already been granted and three others protected. To apply the above combined inventions to suitable carriages and vehicles, and to publicly demonstrate the utility and practicability of the same. To realise the above inventions by the sale of the patent rights to another Company (or otherwise) at a sum which shall yield a substantial profit to the shareholders herein. The Syndicate does not propose to manufacture for sale commercially the inventions acquired, and we note with satisfaction that the public are not invited to take up capital, the idea of the Syndicate being to complete the result of their experiments with their own money before offering shares publicly for subscription. It is claimed that the Company's battery will be enabled to store current in a minimum space and at a weight so much under what has hitherto been known, that it places an entirely new aspect upon the possibilities of electric traction, it being stated that an efficiency of over 90 per cent. has been obtained from the Syndicate's motor. It is proposed to apply the motive power to vehicles of the American buggy type. In some comparative results issued with the prospectus are given some remarkable figures, wherein it is stated that in a cell of the same capacity as one of the best-known makes, that owned by the National Motor-Carriage Syndicate is nearly one-third less weight and only half the size, or, in other words, a battery occupying the same space would propel the carriage double the distance. We are pleased to say that directly the battery and motor are working in a practical form we have arranged to obtain the fullest technical details for the information of our readers. The secretary is Mr. V. C. Doubleday, and the offices are at 37, Walbrook, E.C. Mr. S. A. Rosenthal is the consulting engineer and electrician.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles. We shall be pleased to reply with detailed particulars to inquiries through the "Answers to Correspondents" column. All communications should be addressed to the Editor. The only stipulation which we make is that where the inquiry involves a search of the records at Somerset House—as in the case of information on the subject of the holdings of shareholders—a postal order must be enclosed to cover the Government stamp of one shilling which is charged before a search is allowed to be made.]

	Capital.
Birmingham Cycle Co., Ld	£2,000
Compressed Air Traction Co., Ld. (39, Coleman St., E.C.) ..	125,000
Crawford Cycle and Motor Co., Ld. (4, Mesnes St., Wigan)	10,000
Diplock's Patent Traction Engine Haulage Syndicate, Ld. (37, Queen Victoria St., E.C.)	10,000
Engineer Cycle Works, Ld. (York)	22,000
Franco-English Motor-Car Factory Co., Ld...	22,000
Griffin Foundry Co., Ld. (Stephenson St., Birmingham) ..	50,000
Harris's Micrometer Hub Adjustment, Ld.	5,000
Maxim Foreign & Colonial Motor Syndicate, Ld. (Wool Exchange, E.C.)	35,000
Root's Oil-Motor and Motor-Car, Ld. (100, Westminster Bridge Rd., S.E.)	30,000
Spider Motor-Car Syndicate, Ld. (Liverpool)	1,000
Windsor Cycle Co., Ld. (Featherstone Buildings, High Holborn)	25,000

The Work of Traction.—Some interesting tests have recently been undertaken in France with regard to the power required for the propulsion of vehicles, fitted with wheels with ordinary iron rims and pneumatic-tyred wheels, and the results show a marked all-round advantage by the pneumatic wheels. A Table of the pull required, reduced to kilogrammes, shows the results with different roads and different loads:—

	Iron Rims. Kilogs.	Pneumatic Tyres. Kilogs.
Snow.		
Empty vehicle, walking	17·86	11·45
" trotting	29·60	15·27
150-kilogramme load, walking....	17·83	12·71
" " trotting....	31·17	17·96
Wet Roads.		
Empty vehicle, walking	16·00	10·50
" trotting	19·55	12·97
150-kilogramme load, walking....	17·30	12·43
" " trotting....	23·00	14·16
New and Dusty Road.		
Empty vehicle, walking	17·42	14·05
" trotting	20·41	15·95
300-kilogramme load, walking....	20·75	19·14
" " trotting....	29·70	16·40

Experiments were also made with various pressure in the tyres—3 and 4½ atmospheres—but there did not seem to be much difference between the two.

CORRESPONDENCE.

**** We do not hold ourselves responsible for opinions expressed by our Correspondents.*

**** The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

THE BRITISH MOTOR-CAR SYNDICATE PATENTS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Would you be kind enough to favour me with an answer as to the British Motor-Car Syndicate Company's patents?

I wish to make a motor three-wheel cycle for my own use. Can they prevent me from using a tube ignition to an oil-engine which I shall use for the power? I can remember the tube ignition for more than 10 years, the patent of which should have now run out, but I find by their advertisement that they claim all the various methods of tube ignition, electric and explosion by heat, &c.

I shall be very pleased to be enlightened on this matter, and shall esteem it a great favour for your reply, or you could probably inform me where I could get the information. Trusting you will oblige.—Yours faithfully, Chas. Watson.

[You cannot do better than read carefully Sir David Salomons's paper on "Motor Traffic," contained in The Automotor and Horseless Vehicle Journal of May 15th, 1897, p. 302, *et seq.*, and after digesting the information, pass on the paper to every one you know who is similarly desirous of constructing a motor-car. Moreover, instruct your local M.P. that he must make an amendment of the British Patent Law a plank in his platform.—Ed.]

AN AUTOMOBILE CLUB FOR GREAT BRITAIN.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I take the liberty of enclosing a prospectus setting forth the objects, &c., of the Automobile Club of Great Britain, as well as regulations, from which you will learn that the leading characteristics of this new club will be that it should adequately represent, protect, and foster the true national interests of the new industry.

When I undertook the first steps for forming this new institution I could not quite banish some sorrowful feelings, for when, 18 months ago, I took the initiative regarding the formation of the Motor-Car Club, I thought to render the motor-carriage industry a service, and it was with this intention also that I organised for the Motor-Car Club the receptions to the Houses of Parliament and Exhibitions, &c., last year, in the carrying out of which I was so ably assisted by our popular Mr. Moore.

Unfortunately, the Motor-Car Club, like the Self-Propelled Traffic Association, seems to have turned out more or less a single man's institution, to avoid which was once my very object for forming the Motor-Car Club.

Although I am only too happy to admit that both the Motor-Car Club and the Self-Propelled Traffic Association have undoubtedly done some excellent work, there seems to prevail just now a kind of stagnation, nay in some cases almost unkindly feeling towards motor carriages.

Such a state of things is, of course, very unwholesome and undesirable for a young industry, the progress of which seems seriously checked. In such critical times much disinterested and true support and guidance is wanted, and it therefore appears to me just the very moment that those interested in the new movement and sympathising with same should rally round one institution, whose only object is to support, protect, and further the interest of the new industry, which, considering the hitherto great achievements of Great Britain in locomotion on land and water, is likely to become very important. I have every hope that in course of time this will be well accomplished by the Automobile Club of Great Britain.

No doubt you will be pleased to hear that our friend, Mr. C. Harrington Moore, with all his vigour, courtesy, and general knowledge in motor-car matters, is kindly assisting me in the organisation of the new club, to which he will act as Secretary *pro tem.*

I shall be happy to give any further information on the subject, and have the honour to remain, yours truly,

12, Norfolk Street, Strand, London, W.C. Frederick R. Simms.

[We refer to this matter elsewhere.—Ed.]

"Is Visione About?"—We rubbed our eyes when we learnt that the Post Office authorities had actually ordered a motor-car, and when the same appeared last week in St. Martin's-le-Grand we asked ourselves, Has there been a revolution? Allowing for the usual official inertia, we had given the Post Office just 25 years in which to recognise the fact that automotors of any kind are preferable to horse-drawn vehicles for parcels and postal services. Really this haste is quite unseemly, and altogether foreign to the traditions of the G.P.O. What has caused this enterprise?

Sunderland Engineering Exhibition.—An exhibition is announced to be opened at Sunderland in November, 1897, under the title of Engineering, Mining, Electrical, Marine, and General Trades Exhibition. As the title implies the scope is fairly wide, the classification being divided into 14 departments and 65 sections, which for a Sunderland Exhibition is somewhat ambitious. Department D comprises self-propelled conveyances, the subsections being (*a*) horseless carriages of every description; (*b*) motors suitable for conveyances, carriages, yachts, boats, and cycles. Department E includes locomotives, engines, carts, and other rural means of transport. Full particulars can be obtained from the Secretary of the Exhibition, Mr. H. H. Pinkney, at the offices, 32, Fawcett Street, Sunderland.

Fire at the I.E.S. Works.—We regret to learn that on the 24th ult. a fire broke out at the Woking works of the International Electric Storage Accumulator Company, one of the main buildings being completely destroyed by fire. The outbreak occurred about 5 a.m. in the drying room from an unknown cause, and was followed by a slight explosion, cause of which is also unknown; the fire afterwards spread to casting shop in same building, which was speedily reduced to ashes. The damage, which is covered by insurance, consists of destruction of casting shop, drying room, and loss of a considerable number of plates; most of the machinery and tools were saved, and are in use again. The interruption to business will be very slight, delay only being in execution of orders for plates which were destroyed in drying room. New buildings will be shortly erected, with increased facilities for quick delivery.

Catalogues.—We have received from Messrs. Alley and Maclellan, of the Sentinel Works, Glasgow, an exceedingly well-got-up handbook of their specialities in stationary motors. As is well known, Messrs. Alley and Maclellan manufacture in Great Britain the Westinghouse type of simple and compound engine—one of the best designed and most carefully-finished motors we know of. These motors are specially suitable for small powers, and where weight and space are serious considerations. They are characterised by great simplicity, there being few parts, easy of access, and not exposed. There are no packed joints, no guides, no crossheads, no piston rods, and no stuffing glands. They are constant thrust engines, and all working surfaces are very large, and the lubrication is copious and continuous. Lastly, their first cost is considerably less than that of any other first-class engine. Having used the Westinghouse motor, we speak from experience.

THE PARIS-TROUVILLE MOTOR-CAR COMPETITION.

Motor-car competitions in France seem to threaten to rival in popularity horse racing, and it is certainly time that a substitute was found for the latter antiquated aud unintellectual form of "sport." Hardly have the Paris-Dieppe and Les Poids Lonrds Competitions terminated than another was in progress. This was a race or run from Paris to Tronville aud took place on the 14th iust. It was essentially a light vehicle competition reserved exclusively for motor-voitures and motor-cycles. The former were to carry not less than two persons side by side, and the latter must weigh not less than 200 kilos. = 440 lbs., without stores, &c. The course was from Paris to Tronville, the route being St. Germain, Ecqnevilly, Flins, Epove, Mézières, Mantes, Rolleboise, Bonnieres, Chaffour, Paxy-sur-Eure, Evreux, Parville, La Mère Odue, La Commanderie, La Reviere Thebouville, Foulaine-la-Foret, Boisnet, Bazoques, Lieurey, Cormeilles, Les Authiux, Pont Leveque, Touques, Trouville, the distance being 173 kilometres, or 107·3 miles.

The route was not excessively hilly, there being but four or five steep hills to negotiate and much of the road was nearly level, finally ending iu a gentle descent to Trouville. Prizes to the value in all of about 11,200 francs were given away. Among those who subscribed to the funds we noticed the uames of Mr. Gordon Bennett, 1,000 francs; Lord Rothschild, 500; Baron de Zuylen, 200; *Le Journal des Sports*, 1,000.

As usual on these occasions much of the execution work was performed by the editorial staff of the latter journal, the managing director and editor, MM. A. de Lucenski and J. Aubry, acting as starter and clocker. The arrangements were much the same as were made in the Paris-Dieppe race, inclnding au exposition at Trouville.

There were 64 entries, all of which, excepting a De Dion Steam Brake, were light oil vehicles, and they included five Panhard and Levassor, eight Bollée, three Benz, and 13 De Dion et Bouton motors. Many of those who competed in the Paris-Dieppe contest also competed in this, including M. Jamin, who won the former in his Bollée voiturette.

Of the 64 entries 48 started, and the wiuner was again M. Jamin on his Bollée voiturette, doing the distance iu 3 h. 51 m., or at the astonishing rate of 27·8 miles per hour. Many other runs were improvements upon previous performances. Unfortunately, the festivities at Trouville were at the last moment clouded by a serious accident. One of the motor-car competitors came to grief at Pont Leveque, a few miles out of Trouville, and the rider, if uot killed, is so severely injured that he is not likely to recover.

The Princesse de Sagan, who takes great interest in the motor-car movement, had arranged to entertain all the competitors and their friends, to the number of 150, at a banquet on the new pier, but owing to this sad affair it was countermanded.

MOTOR-CAR PROSPECTS.

The *Rialto* and *Financial Times* last month both published the following:—

"Those who are interested in the possibility of motor-cars as a method of road locomotion might do considerably worse than read the interview with the heads of the engineering firm of Messrs. New and Mayne, which is published in this month's issue of The Automotor and Horseless Vehicle Journal. The firm apparently feels internal anguish at the suggestion that there is no such thing as an automotor industry in this country. We never doubted it ourselves; for did not a representative once go down to Coventry and walk around Mr. Lawson's amalgamated factory? However, it is something to know that 'quite a number' of firms are working at electrically-propelled vehicles, and this time it is Mr. A. New who promises 40 or 50 electric cabs in London before long. Mr. New thinks that the weight of a motor-van for carrying 1½ tons of goods would be but 30 per ceut. heavier than a horse-van. The initial cost of a motor-car would be about 25 to 30 per cent. higher than an ordinary tradesman's van, but the cost of working 50 per cent. less. Depreciation would probably not exceed 10 per cent. per annum of the prime cost. Mr. New has some valuable remarks to offer on the various kinds of cars for use, and the interview is worth perusal or cutting out for reference when motor-cars shall have emerged from their embryo stage."

The Royal Agricultural Society's Show.—This show will next year be held at Maidstone, from June 20th to 24th inclusive. The implemeut yard only will be opened on the Saturday previous, June 18th. It has been decided to again offer, in connection with the Maidstone Meeting of 1898, the following prizes for self-moving vehicles, viz.:—Class I. Self-moving for light loads, first prize, £100; second prize, £50. Class II. Self-moving vehicles for heavy loads, first prize, £100; second prize, £50.

A New American Electric Motor-Carriage.—Professor Elihu Thomson is stated to have been at work for two or three years experimenting upon a motor for carriage propulsion. An American paper says that the professor tried various elements, such as gas and gasoline, and various oils, but finally returned to his first love, the electric motor, and while the experiments have been conducted with much secrecy in temporary buildings uear the works of the General Electric Company, in Lynn, it is now understood that the perfected electric carriage will shortly be in readiness for public use. The motors are to be placed on the rear axle of the wagon, aud a speed of 20 miles an hour can be easily maintained. The electricity will be supplied from a storage battery of greatly reduced weight. The motor is light, and the steering attachment is to be connected with the front wheels. Simplicity and durability are the prevailing characteristics of the mechanism.

The Motor-Car Industry in France.—The motor-carriage industry has taken root far more readily in France and in other Continental countries than it has done in England. There are upwards of 40 firms manufacturing self-propelled vehicles in France, and the new industry is in a much more prosperous state across the Channel than it is here. The French have, says the *Practical Engineer* in a recent issue, a decided preference for mechanical road-traction, for they are not so squeamish about considerations of vibration, smell, and other minor drawbacks so long as they find autocars more economical than horsed vehicles, and, while most of the existing tramways are being equipped with cars propelled by steam, electricity, or compressed air, it is stipulated that on all new lines that are laid down mechanical power must be used. The result on the tramways has been that the service is not only vastly improved and made quicker and more regular, but it works out at a considerably reduced cost, so that many a line formerly working at a loss is uow making large profits. The experieuces of the experimenters with oil-driven motor-carriages have apparently uot been very encouraging, and all the manufacturing firms are more sanguine about the future than satisfied with the present. In regard to steam, the chief progress recorded seems to have been made by the Scotte road train, which in the transport of passengers has been put to very severe tests in various parts of France, and has come through the ordeal very satisfactorily. It is an omnibus train consisting usually of the motor carriage with a large omnibus attached to it, and the experimental service of these steam vehicles between Courbevoie and Colombes, in the environs of Paris, has, during the month or two for which the road trains have been at work, given every satisfaction not only to the public but also to the different local authorities from various parts of the country who have seen the system, and, having beiug especially pleased with the absence of the injurious effects of the traffic on the roads, have beeu considering the advisability of adopting it for passenger service in their several rural districts.

PROCEEDINGS OF SOCIETIES.

The Decimal System in Engineering Measurement.*

Broadly speaking, the decimal system is used in engineering in this country whenever calculations other than mere checking have to be made, or when very accurate dimensions have to be expressed; and in either case, in mechanical engineering, the decimals are generally those of the inch, its square, or its cube. The reason of this is fairly obvious. As regards calculations, decimals are, on the whole, far simpler than vulgar fractions, and they allow of the ready use of the slide-rule or of tables of logarithms.

It is true that occasionally simple vulgar fractions have to be dealt with, as, for instance, one-sixth in the case of the formula for the strength of a rectangular beam. In such cases the vulgar fraction would obviously be used; to convert to decimals would correspond to using a slide-rule or a book of logarithms to multiply 6 by 5, or some such simple sum.

In the case of accurate dimensions in mechanical engineering, $\frac{1}{64}$ inch is far from being a sufficiently small dimension; hence the use of the terms bare and full; and as, for interchangeable work, such vague dimensions are very unsuitable, recourse is naturally had to the use of $\frac{1}{100}$ inch and $\frac{1}{1000}$ inch. The writing down of accurate dimensions is also very cumbrous even when they can be expressed by $\frac{1}{64}$ inch.

Compare, for instance, 11 inches + $\frac{15}{16}$ + $\frac{1}{32}$ + $\frac{1}{64}$ bare with its decimal equivalent 11·98 inches. No doubt the same dimension may be more briefly expressed as $11\frac{63}{64}$ inches, but this form is not generally used in practice, and there are obvious reasons why this should be so.

It will be observed that the decimal expression has only been carried to the second place, and this is because the uncertainty in $\frac{1}{64}$ inch "bare" is of the order of $\frac{1}{100}$ inch. If the decimal expression is extended to the third place, an order of accuracy is reached expressed by $\frac{1}{1024}$ inch on the binary scale, fractions which are not practically workable.

When dimensions of no special accuracy have to be stated, the natural tendency to successively divide the unit by two gains the upper hand. Notwithstanding this tendency and the prevailing custom, it can scarcely be doubted that it would be preferable to state all such dimensions in decimals of an inch.

If decimals of an inch are adopted, the system is still incomplete, owing to here being 12 inches to the foot, 3 feet to a yard, and so on.

It is here that the metric system has a great advantage—it is a decimal system throughout. As experience in such a matter has more value than mere theory, a statement of the results of introducing the metric system of linear measurements into the works of Messrs. Willans and Robinson may be of interest.

In the first place, it is desirable to say a few words about the class of work and method of manufacture carried out at the works in question.

The Willans central-valve engine and the Niclausse water-tube boiler are manufactured, each in certain definite standard sizes, and the parts required are made to gauge and template in large batches, and have to conform to fixed dimensions within specified limits of accuracy, in order that strict adherence to the interchangeable system may be maintained.

In the machining and examination of the parts, gauges and templates are used, as far as possible, to the exclusion of the measuring rule. Whether inches or millimetres are used is, therefore, not a matter of much importance.

At the marking-off table the measuring rule is, of course, more used, and the question of convenience in the unit of measurement, and its divisions, is of greater importance. The parts are, however, dealt with in batches, and the convenience or otherwise of the unit of measurement, and its divisions, tells once only for each dimension for the whole batch.

The circumstances that led to the adoption of metric linear measurements are not of general interest, and, for reasons which need not be entered into here, they were only applied to the Niclausse boiler and to certain sizes of the engine, the earlier sizes being still made to drawings figured in feet and inches. Thus the two systems are concurrently at work in the same shop.

There would have been no advantage in refiguring these drawings with equivalent millimetres, and to make new parts to millimetres to interchange with old parts made to inches would be impossible without going to several places of decimals. The old gauges and templates were marked with the millimetre equivalent to the third place of decimals, but this was merely to accustom the men to sizes expressed in the new system. It may be mentioned that the men were supplied with rules marked with millimetres on one side and inches on the other.

The expense involved consisted principally in providing a complete set of gauges. New templates and jigs had also to be made, but only a portion of their cost is properly chargeable to the introduction of the new unit, as the greater number of them would have been required in any case.

The only difficulty met with has been in connection with the screw threads. Hitherto the ordinary Whitworth and gas threads have been retained; but, for reasons connected with the manufacture of the engines abroad, the body of the bolt or stud is turned larger than usual, the excess being 0·3 millimetre for $\frac{1}{2}$-inch Whitworth, and 2 millimetres for $1\frac{1}{2}$-inch Whitworth; intermediate sizes are in proportion, all being brought up to even millimetres. The bored holes are then able to take the corresponding screw cut to the standard used by the French makers of the engine, who use the thread of the Société d'Encouragement, which is slightly larger than the Whitworth, and which, it is stated, promises to become universal in France; it is now adopted by the French navy and railways.

The metric dimensions were introduced in May, 1893, and, after four years' working, the following is the result:—

No difficulty has been experienced in getting draughtsmen to use the new measures. No serious mistakes have been traceable to the change, and very few minor ones. The draughtsmen are practically unanimous in favour of metric measures, finding it easier to design, to check, and to read millimetre drawings. Taking all fractions into account, little more than half the number of figures formerly used are now required to express a dimension. An average case would be 3 feet $1\frac{3}{8}$ inch, which, on a millimetre drawing, would be figured 949; and an extreme though possible case is 3 feet $1\frac{3}{32}$ + $\frac{1}{64}$ inch bare, which becomes 942·4.

The need to use decimals of a millimetre is very infrequent, but in the case of inches the use of fractions is, of course, the rule. A cylinder, for example, might be figured 2 feet 6 inches on an inch drawing, and 770 on a millimetre drawing; the piston body must have a certain clearance, say $\frac{1}{32}$ inch in one case, or 1 millimetre in the other, in which case it must be figured 2 feet $5\frac{31}{32}$ inches on the inch drawing, whereas on the millimetre drawing the dimension becomes simply 768, and the use of fractions is wholly avoided.

The proportions between dimensions are more readily appreciated when expressed in millimetres; thus the ratio between 27 millimetres and 49 millimetres is much more easily apprehended than between $1\frac{1}{16}$ inch and $1\frac{15}{16}$ inch.

A point of some importance is that the ordinary foot- and inch-ticks or marks are not required, and with them disappears the possibility of having 2 inches added to each 10, or deducted from each foot in a dimension. A case of this kind occurred in which two 13-inch flanges intended to come together were shown on different drawings; in one of them a tick was introduced after the one, and that flange was made 1 foot 3 inches.

With millimetres a cypher might possibly be put in, or omitted; but a dimension ten times too big or too small, would at once be noticed as absurd.

In the drawings, scales 1, $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{10}$, and occasionally of $\frac{1}{20}$, $\frac{1}{5}$ are used. It is found that this number of scales is amply sufficient.

No mistakes have been made in marking off work to millimetres. The men preferred the old system at first, the new figures conveying little idea of size; but they are now much in favour of the millimetre, and find drawings so figured easier to read. The shop where the difficulties of the change would be most felt is that in which the tools and gauges are made; the foreman says that it was a little awkward at the outset—for about two days.

In the works manager's opinion, the metric system would prove even more advantageous in shops where measurements are taken from the rule than where gauges are used. He considers it easier to teach men the use of the rule with the metric than with English measures.

* Paper read at the proceedings of the Institution of Civil Engineers, by Henry Riall Sankey, Capt. R.E. (ret.), M. Inst. C.E.

The Value and Scope of Inland Navigation.*

Although the development of inland waterways in England has been considered and discussed in a desultory sort of way during the last decade, the all-powerful and far-reaching influence of the railways has no doubt delayed any decisive steps being taken in the matter.

The first step to be taken is to persuade the railway companies who own waterways, and even those who do not, that a system of properly constructed canals would act as an auxiliary and not as competitors in their trade, and that the two could really be worked together with advantage—minerals and other heavy goods being sent by water, and the lighter traffic reserved for the railway.

The disadvantages of waterways may be summarised under the following four headings:—

(i) The speed of traffic is necessarily somewhat slower than by rail.

(ii) The difficulty of increasing the normal speed, owing to its being regulated by the number of stoppages at the locks.

(iii) The probable disorganisation in the winter by frost, and in canalised rivers by floods.

(iv) The difficulty of arranging the levels so as to suit existing works, and the almost absolute necessity for discharging by means of a crane or other mechanical power.

The first disadvantage is in reality no disadvantage at all; it is not proposed to carry goods by canal which are required immediately, and when cost is as important as it is to-day, a trader would and does soon become accustomed to allowing sufficient time for the slower carriage of his goods.

Again, both Nos. (i) and (ii) could in any modern system of canals be much modified by the use of hydraulic lifts similar to those at Anderton and Les Fontinettes, which not only save water but obviate long flights of locks by a single fall of perhaps 50 or 60 feet.

The chief reason for No. (iii) being at present such a formidable disadvantage lies in the fact that there is little or no steam-propelling power in use on the canals, and that the sectional area and depth is so small.

Were steamers more in use, and suitable ice-weirs provided, there are very few winters in England when, by the judicious employment of labour, plentiful at such times, waterways could not be kept partially, if not entirely, open.

The fourth disadvantage has already been very successfully overcome, at any rate for bulk traffic, such as grain or coal, by the ingenious contrivance devised by Mr. Bartholomew on the Aire and Calder Navigation.

For the handling of other goods, either for discharging or transhipping purposes, the steam derricks employed on the River Weaver have been found not only rapid but economical, especially when they are fitted either on a suitable craft or are carried by the steamers towing the train of boats.

The advantages of waterways may, on the other hand, be summarised as follows:—

(i) Goods can be carried in greater bulk than by rail.

(ii) Boats can load or discharge at any point on the banks without risk of collisions or the construction of special sidings.

(iii) For fragile, or partially fragile, articles, such as bricks, pipes, light castings, &c., there is less liability of breakage.

(iv) The cost of repairs and maintenance both of the canal and moving plant is less, thereby lessening the cost of carriage.

It is quite evident that large quantities of mineral and other bulk traffic can be carried more advantageously in boat loads than in small wagon loads, and where small quantities of numerous articles are required, the difficulty can be overcome by what may be termed "omnibus" boats owned by "carrying companies," or even the canal company itself, which have a regular service, with receiving and delivery offices or sub-offices. On the Weaver a large trade is carried on in this manner, and comparatively small individual quantities of goods are carried from Liverpool to any point on the river at which they may be required: whether such point is a properly constructed dock or wharf, or only a field, the long jib of the steamer's derrick landing the load well on shore, even if the bank is unprepared.

It is seldom there are any complaints of breakage. It is, of course, useless to expect a full development of canals until there is uniformity of width and increase of capacity, the present narrow canal boat carrying, perhaps, 25 tons or less, requires the same crew as one of 10 times that capacity, and the power

* Paper read at the Engineering Conference, by John Arthur Saner, M. Inst. C.E.

required for towing in a proper section of waterway would be very little if at all increased. The actual cost of salt carriage on the River Weaver is somewhat under ½d. per ton per mile, including all interest, depreciation, stores, wages, and toll.

After mature consideration of the question of gauge the author is of opinion that a canal 40 feet bottom width, 72 feet surface width, 8 feet deep, and having therefore 443 square feet sectional area, would accommodate vessels 75 feet long, 18 feet beam, 7 feet draft, and of about 210 tons displacement.

The locks should be made to accommodate either two or four of such craft; in the latter case a steamer and train of three could pass through at once, saving much time. The advantage of adopting such dimensions would be that all the existing boats could be used until worn out without undue waste of water at the locks and lifts.

In conclusion, the value of inland waterways is at present at a discount owing to want of organisation; their scope of usefulness is greatly restricted from the same cause; but both the value and scope could be enhanced on the lines briefly sketched herein, and the question is one of such importance that it is worth the consideration of a special committee of politicians and engineers appointed to fully investigate and report on the most practical and economical method of placing inland waterways in the position they should occupy in the economy of the country.

The Value and Scope of Inland Navigation.*

THERE are at the present time frequent instances in which the old-world "monkey-boat" canal, practically in the same primitive condition as when it was constructed at the end of the last century, successfully holds its own in spite of, and in the very teeth of, the competition of first-class main-line railways equipped with every modern appliance.

Examples which occur to the author, and of which he has an intimate personal knowledge, are the Staffordshire and Worcestershire Canal, the Worcester and Birmingham Canal, the Oxford Canal, and the Warwick Canals, the latter forming part of the waterway from Birmingham to London.

These canals are all free from railway control. They are essentially narrow canals, their dimensions being roughly a top width of 40 feet, a middle depth of from 4 to 4½ feet, and with locks capable of passing a boat 70 feet long by 7 feet beam, and carrying at most 35 tons, more frequently only about 25 tons.

On none of them can steam haulage be profitably employed, whilst shallow locks abound throughout them, and mechanical lifts or other time-saving appliances have nowhere been attempted.

They are, in fact, mere ditches and of a most antiquated type, and yet, although they are in each case in direct competition with first-class lines of railway, they pay their way and carry a considerable through traffic—a fact which, *per se*, constitutes strong evidence of the value of inland navigation.

The consideration of this fact also leads directly to the question of the scope of inland navigation and of its possibilities if a systematic development of the waterways should be undertaken.

At present the canals cited merely serve the purpose of keeping down railway rates. This is certainly a useful function, but, nevertheless, falls far short of the full capabilities of a modernised system of inland navigation.

The canal of the future must do much more than this. With well-planned improvements it has within its scope the reduction of the cost of carriage of heavy goods to a point far below anything which can be attempted by railway haulage unless it happens that the present railway charges are inordinately in excess of what they should be.

For these benefits to be reaped to the full, however, the sectional area must be increased, bridge spans must be widened, and changes of level must be concentrated and overcome by mechanical lifts.

Such an alteration in the canal will permit of a large bulk of goods being conveyed in one bottom instead of in many small canal boats, and of the substitution of mechanical propulsion for that of men and horses, as at present.

If with such improved conditions the administrative arrangements are also modernised and regular services established the cost of conveying goods may be reduced to about one-half of what has been possible upon the old type of canal, the extent of the reduction depending very much upon the nature of the improvements.

The actual extent of the improvement, and the sectional area to be aimed at, might be supposed to depend mainly upon the quantity of traffic which such improvement would be likely to draw to the canal, but there are frequently other determining factors.

The author has had on several occasions to make surveys and prepare estimates for the improvement of canal navigations, and he has always found that there is a point up to which improvements may be carried out at a moderate cost, but that owing to some local circumstance the moment that point is passed the cost increases inordinately.

In such cases it is prudent to carry out the least costly scheme in the first instance, even if it should eventually necessitate a portion of the work being done twice over.

As an instance, he may mention that he has recently had to report upon the cost of improving the waterway between Bristol and the South Staffordshire iron district, and he found that out of the whole distance of 103 miles, no less than 78 from Bristol inland were navigable by barges of 225 tons carrying capacity, or could be made so with a few inexpensive alterations.

For the last 25 miles, however, the waterway—the Staffordshire and Worcestershire Canal—was navigable by small canal boats only, and very early in the investigation it became obvious that whilst the navigation could be adapted to the 225-ton barge or its equivalent right up to Wolverhampton at a moderate outlay, any increase, however slight, in size of vessel to be accommodated would require costly alterations in the lower reaches.

He has therefore advised the Improvement Committee to confine their efforts for the present exclusively to the enlargement of the 25 miles of canal, so that it may be of the same capacity as the remaining 78 miles of the navigation.

He has recommended that the improved canal shall have a top width of 60 feet, a bottom width of 40 feet, and a depth of 7 feet, with locks capable of passing vessels 85 feet long, 19½ feet beam, and drawing 6½ feet.

He estimates the cost of the work at £360,000, which includes a provision for reducing the number of ponds into which the canal is split up from 31 to 11, substituting inclined plane lifts in many places for the numerous groups of locks. It also provides for a number of straight cuts which will do away with awkward bends and shorten the travelling distance by 2¼ miles.

* Paper read at the Engineering Conference of the Institution of Civil Engineers, by EDWARD DIMMACK MARTEN, M.A., M. Inst. C.E.

The outlay represents an expenditure of £16,000 per mile of finished canal as compared with the original inclusive outlay upon existing canal of under £6,000 per mile.

The improved navigation will accommodate not only a 225-ton barge for use between Bristol and Wolverhampton, but also a thoroughly seaworthy steamer capable of running between Wolverhampton and London, Liverpool or other ports, and carrying 150 tons, and the writer believes, as the result of careful calculation, that if full and regular return loading can be relied upon, and if the work were done by a Trust not seeking profit beyond what is required to pay interest upon capital invested, the actual cost of conveying heavy goods between Wolverhampton and ship side in London will be little more than half the charge now made by the railway companies.

The subject of ways and means, though not strictly an engineering one, is all-important. Space does not permit of the writer entering upon it, but he ventures to suggest as an exceedingly useful topic for discussion at a conference of experts, the question as to the auspices under which works of canal improvement shall be carried out.

Is there any prospect of its being taken up as a national concern? Or is it to be left to the Company Promoter? Or shall it be put into the hands of a Trust delegated by the district to be benefited, and if so, shall the required capital be raised upon the security of the rates of such district?

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

Specifications Published.

7,333. Gas, Petroleum, or like Motors. Albert Eduoard Le Brun, Montrauge, France. March 20th, 1897.

This invention relates to a new gas, petroleum, or like motor, and relates more particularly to the special arrangement of the fly-wheel, which forms at the same time an engaging sleeve or device, to the parts provided for regulating the distribution and to the control of the pistons.

The improved motor comprises in principle two convergent cylindrical parts,

a^1, the pistons, b^1, b^2, of which travel in the same direction and actuate the driving shaft, c.

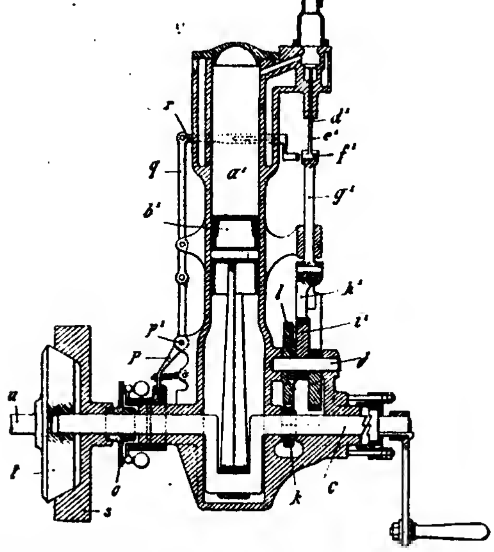
The explosive mixture is admitted to the explosion chambers by any suitable device; its ignition is effected in the usual manner, either by igniters raised to incandescence or by means of an electric spark.

The distribution is effected in the following manner:—

The rods, d^1, d^2, of the inlet valves are raised alternately by the extremities of bell-crank levers, e^1, e^2, pivoted at f^1 and f^2 respectively to the rods, g^1, g^2, to which a reciprocating motion is imparted by means of the connecting rods, h^1, h^2.

These latter are driven by the excentrics, i^1, i^2, respectively which are arranged at an angle of 180° upon an intermediate shaft, j.

FIG. 1



This shaft is driven by the shaft, c, by means of toothed wheels, k, l, which are in the relation of one to two, so that the intermediate shaft, j, makes only half a revolution for each complete revolution of the shaft, c.

This arrangement is regulated in the following manner:—

The shaft, c, imparts its rotary motion to a governor, o, of any suitable description, which acts upon a lever, p, pivoted at p^1. This lever, p, actuates by means of a vertical rod, q, an horizontal bar terminating in a T-shaped portion.

Under these conditions, if the speed of rotation of the shaft, c, increases, the balls of the governor separate, the lever, p, acts upon the vertical rod, q, and the horizontal bar advances in such a manner as to stop the extremities of the bell crank levers, e^1, e^2, as they rise, and prevent the latter from acting upon the corresponding rod, d^1, d^2, of the inlet valve.

The admission of the explosive mixture is thus interrupted until the speed of the shaft, c, again becomes normal, for when this has taken place the balls of the governor again approach each other, the vertical rod, q, moves back, bringing with it the horizontal bar, r.

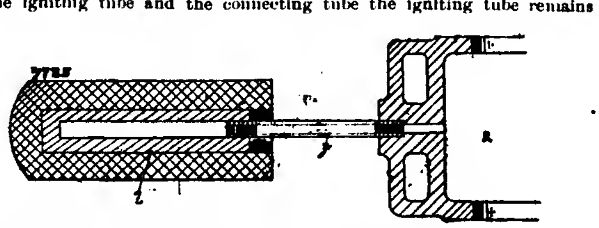
The shaft, c, carries a fly-wheel, s, of a special kind, which forms also an engaging sleeve, acting upon a conical pulley, t, fixed upon a shaft, u, which communicates the motion so imparted to it to the different parts to be actuated.

Engagement and disengagement are effected by imparting a motion of translation to the shaft, u.

The shaft, c, carries at its free end a crank or handle by means of which the motor can be started.

7,785. Automatic Igniting Apparatus. Donat Bánki, 11, Rorsahegy utca 6, and Johann Csonka, of Szövetség utcza 5, Budapest, Hungary. March 25th, 1897.

This invention consists in connecting an igniting tube, Z, by means of a thin tube, z, with the combustion chamber, R. By employing suitable dimensions for the igniting tube and the connecting tube the igniting tube remains



glowing without exterior heating, but only by the heat derived from the explosions in the cylinder and the lighting operated by this glowing tube is effected regularly near the dead point.

A tube, z, which has to be kept glowing by the explosion heat, must be composed of an appropriate material which receives heat well, and must have a surface receiving a great heat in proportion to the heat delivering surface; also the igniting tube must possess a sufficient mass in order to receive and hold a corresponding quantity of heat in itself. In order to correspond to all these conditions there must be used a tube about 4 to 6 mm. thick (preferably of copper) with a bore not less than 6 to 7 mm. A thin igniting tube, as used for ignition in explosion motors with exterior heating, is cooled, as soon as the exterior lamp is taken away, and has therefore not the property of automatic ignition.

In this lighting tube, composed of the two parts, Z and z, the part, Z, has a high ignition temperature, whilst the tube piece, z, will never obtain so high a temperature, that is to say, it can keep a lower temperature than is necessary for ignition from the explosion period up to the moment of ignition. The ignition is therefore effected by the tube, Z, and an ignition by the tube piece, z, is excluded.

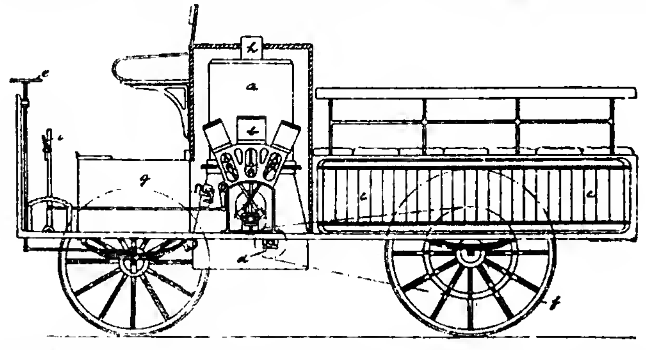
This property of the thin connecting tube, z, gives the explanation for the fact that by inserting this tube early ignitions are avoided.

At the beginning of the compression the whole tube, Z and z, is filled with uncompressed combusted gases, but before the tube opening there is the combustible mixture. On compression, the combustible mixture penetrates first into the thinner tube, z, and moves the expanded gases into the tube, Z. In consequence of the rising compression there would pass continually explosive mixture from the tube, z, into tube, Z, which mixture is ignited by the hot walls of the tube, Z, and will continue burning on the tube opening, z. Near the inner piston dead point the piston velocity becomes less, the compression and the current through the tube, z, will therefore become weaker, until the flame moves finally through the tube, z, back into the cylinder interior.

10,478. Motor Road Cars. James Compton Merryweather and Christopher John Wallace Jakeman, of the firm of Merryweather and Sons (Limited), Greenwich Road, Greenwich, Kent. May 15th, 1896.

Relates to improvements in the construction of self-propelled carriages actuated by steam.

In one form use is made of one of the patent boilers (No. 1855—80) as used in steam fire-engines, fitted with an automatic gear for feeding the boiler with water, and an automatic gear regulated by the steam pressure for controlling the supply of liquid fuel to the furnace. In order to dispose of the exhaust steam a compound engine is used, preferably with three cylinders, which exhaust at a low pressure into a surface condenser formed of flat copper tubes



preferably under the vehicle. The water from the condenser is collected in a closed tank, and any remaining vapour is conducted into the uptake through a superheater. The engine and boiler are carried on a light steel frame, and the carriage body, which may be closed or open, is supported thereon by suitable springs. The wheels are fitted with elastic tyres, covered with a preparation of leather to reduce the wear, and are arranged to run freely on fixed axle arms, two of the arms being pivoted at suitable points for the purpose of steering. Gearing is provided for varying the relative speed of motor and carriage, and balance gear is fixed on the intermediate shaft to allow for turning curves.

A is the boiler, B the engine, C the condenser, D the balance gear, E the steering wheel, F the driving wheel, G water tank and coal bunker, H is the uptake from the boiler, and I the reversing lever.

10,424. Cooling the Surfaces of the Cylinders of Explosively-Driven Engines. Frederick Richard Simms, 12, Norfolk Street, London. May 15th, 1896.

The ribs employed for the cooling of the explosion chambers are made so as to project radially outside the cylinder, and are made larger and larger in diameter as they approach to the back end of the cylinder, so that the outline will resemble that of a frustrum of a cone. The ribs may form helixes round the cylinders. The ribs or projections are curved so that their peripheries are turned towards the front of the cylinders, and holes or slots are made in these ribs or projections, which holes or slots are preferably to be arranged so that they hit and miss one another; and when projections only are used and not continuous ribs on the outside of the cylinders, these projections are to be preferably arranged also to hit and miss when viewed from either end of the cylinder. The holes or slots are for the purpose of increasing the surface exposed to the air by allowing the air or draft to pass through, and they are arranged and shaped as stated, to cause the air that will impinge upon the surfaces of the ribs or projections to be forced into more intimate contact with the metal of the projections or the ribs, and with the body of the cylinder.

Or the projections may take the form of thin rods or wires projecting from the sides of the cylinders at right angles, in a manner similar to that of the hairs of a brush or broom, and they are curved and increased in depth in the same manner that the ribs or projections previously mentioned are; or these thin wires may be fixed on the outer rim of the projections described.

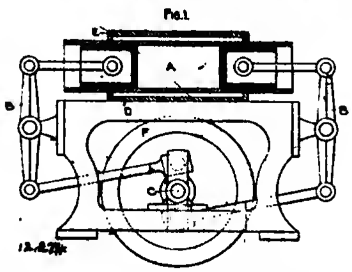
In lieu of curving the ribs or projections so as to present concave surfaces towards the front of the cylinders that it is desirable to cool they may be inclined forward, and this will produce a similar effect.

12,274. Internal Combustion Motors. John William Hunter, Eastdown Works, Dermody Road, Lewisham, Kent. June 5th, 1896.

This invention has for its object the construction of a motor which shal be as free as possible from shock and vibration when in action, so as to render it specially suitable for the propulsion of automobile vehicles and launches, and for use in situations where a rigid foundation is not available.

Description of Drawing.—A, cylinder, showing pistons at half stroke; B, rocking bar, with arms extending upwards to connect with pistons, and down to crank, the connections at both ends of the cylinders being the same; C, crank shaft, having a double throw crank, the cranks and pistons at opposite ends of cylinders being connected together and operated as shown; D, frame supporting the mechanism; E, water jacket; F, fly wheel.

An engine built in this manner has its two cylinders acting alternately, thus

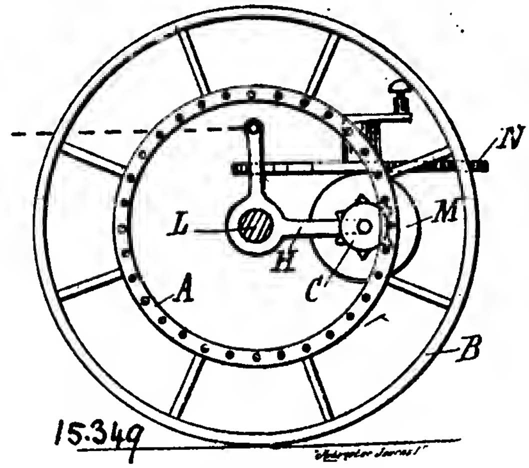


giving an impulse once in every revolution of the crank shaft. Any number of cylinders having their pistons connected in like manner with the rocking bar at each end of the cylinders, all acting on one crank, could be employed; but a much better plan is to duplicate the two cylinder arrangement, using a shaft provided with two pairs of cranks set at right angles to each other, which arrangement will furnish an impulse twice during each revolution of the crank shaft.

This motor may be worked by gas, petroleum, spirit, or any product capable of forming an explosive compound, and is fitted with the usual valves, &c., necessary to the working of a gas or oil engine, and may be fired either by a heated tube or electrically; but these parts are not described or illustrated, they being such as are common to motors of this class. The cycle of operations when the engine is working is as follows in a single cylinder engine:—1, drawing in the charge; 2, compression; 3, firing; 4, exhaust; but any other cycle may be adopted if practicable, and variations in constructional details may be permitted providing the general principles involved are adhered to.

15,349. Mechanism for Transmitting Power in Autocars or Horseless Carriages. Hippolyte Lepape, 23, Rue Montaigne, Paris, France. July 10th, 1896.

The transmitting mechanism is supplied with a toothed wheel furnished with either interior or exterior cogs, or with a lantern wheel, A, held in any convenient way to each of the driving wheels, B, of the autocar, this lantern or other wheel, A, being actuated by toothed pinions, C, keyed on the shaft, D.



This shaft, D, is supplied with a differential motion in case the two driving wheels should be actuated by the motor. The said shaft, D, is held by the two bearings, E, jointed according to Cardan's system, fixed on oscillating arms, H, secured on the axle of the driving wheels, A. Between the arms, H, the shaft, D, has a polygonal section, or is supplied with a long cotter or projection, thus allowing the friction pulley, the hub of which has a similar section, to be placed freely on the shaft, the object of this disposition being to unite intimately the shaft and the pulley in the rotatory motion, and, moreover, to allow the pulley to slide from left to right without the rotation being interrupted.

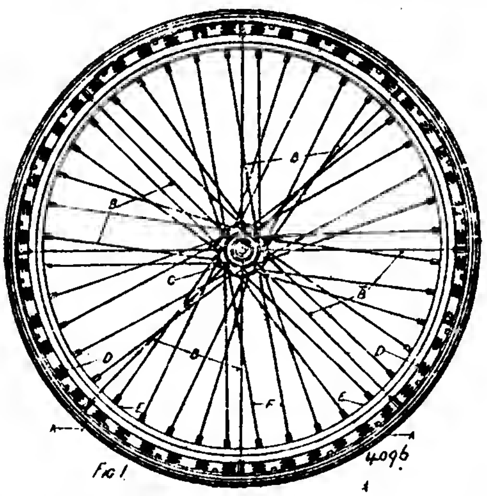
20,141. Tyres for Wheels of Carriages, Motor-Cars, &c. John Ebenezer Hopkinson, Para Rubber Mills, West Drayton, Middlesex. September 11th, 1896.

Relates to the construction of those tyres for carriages and other vehicles which consist of an outer solid or "cushion" tyre bearing upon a pneumatic or air tube, the latter and a portion of the former being enclosed within a metal or other suitable rim.

The outer tyre is formed with a groove on each side so that it may be retained between the re-entrant flanges of a suitably shaped rim. The grooves thus formed in the outer tyre cause the latter to be furnished with inner and outer double flanges. The outer flange may be flat or curved or corrugated or moulded to any desired pattern. The inner flange bears upon the air tube enclosed within the rim and should be curved so as more or less to conform to and partially enclose the air tube. One or more layers of canvas or other fabric are inserted between the outer tyre and the air tube and solutioned or otherwise secured together, great care being taken to make a perfectly secure attachment of all the various parts together. Or the solid tyre may be formed with a groove on each side to be retained by re-entrant flanges on the rim, the rim below the flanges sloping slightly outwards, and the solid tyre having a corresponding shape, the pneumatic tyre being normally narrower than the solid tyre. In this way the composite tyre is kept with approximate accuracy in its position when it approaches the flanges of the rim, and the friction between its sides and those of the rim when it is constrained to move within the rim is materially reduced.

4,096. Wheels for Cycles, Road Vehicles, &c. Richard Thomas Bellemey, King Street, Sydney, New South Wales, and Charles Bellemey, Rush Street, Woollahra, near Sydney. February 15th, 1897.

The tyre, A, is made of wood, or iron, or steel, or like material, and may have an outer facing, or wearing strip, if desired. As shown, this tyre, A, is made segment shape, and of wood, and it has stiffening spokes, B, reaching inwardly



to a ring, or boss, C, set centrally around the hub of the wheel. The spokes, B, are attached to this tyre and to the central ring, C. The springs, D, are shown as helical, though they may be flat, or of other shape, and these springs are placed between the tyre, A, and the rim, E, sitting up against the inner face of the tyre and being fastened thereto, and against the outer face of the rim, E, and being fastened thereto.

It will be seen that in passing over inequalities upon the roadway, that the springs, D, will compensate for those inequalities, and will allow the tyre and the tyre spokes and central ring, C, to flexibly move without affecting, or only very slightly affecting, the inner wheel constituted by the rim, E, the rim spokes, and the hub, and thus very little vibration will be felt.

Various modifications are described.

5,748. Mechanism of Power-Propelled Vehicles. Frederick William Lanchester, Cobley Hill, Alvechurch, Worcester. March 14th, 1896.

This invention relates to improvements in the gearing and controlling and steering mechanism of power-propelled vehicles, and consists, firstly, of the method of controlling the transmission of power by means of a epicyclic train of wheelwork of which a part is acted on by a brake or brakes; secondly, of the method of controlling the relative motion of steering wheels on independent centres by means of separately centred levers arranged to actuate the respective wheels by sliding or equivalent link connection and coupled to one another; and thirdly, of steering mechanism, comprising two independently mounted steering wheels in combination with separately centred actuating levers coupled to one another and to suitable operating mechanism, consisting of a handle bar pivoted to a tiller bar and having a slotted extension in sliding contact with a fixed pin or bracket.

6,740. Gas, Oil, or Hydrocarbon Vapour Engines. Joseph Ibbett, of Market Square, St. Neots, Huntingdon. March 27th, 1896.

The engine is of the inverted cylinder type, and the valves employed to govern the admission of air and gas, and the emission of the exhaust products of combustion may be operated in any convenient manner. Surrounding the upper half of the cylinder is a helical coil of pipe, and this is arranged to be in close contact with the exterior of the cylinder, and is preferably brazed thereto. The lower end of this coil is open to the atmosphere, and the upper end communicates with the interior of the cylinder through the air and gas admission valve. The gas or hydrocarbon vapour is admitted at any suitable point in this coil so as to be mixed in the most intimate manner with the air entering, before passing into the upper end of the cylinder.

The crank and its shaft, together with the connecting rod, is enclosed in an air-tight case, and the reciprocation of the piston acts as a pump and draws in air through a helical coil of tube, which surrounds the lower half of the exterior of the cylinder, and forces it out through a valve in the casing which surrounds the crank and shaft. The current of air which is by this means caused to pass through the coil serves the purpose of cooling the cylinder, or the air thus drawn in may be forced into the upper coil for mixing with the hydro-carbon. The lower end of the casing which surrounds the crank shaft is used as a receptacle for oil, and arrangements may be made to connect this with the different parts of the engine in such manner as to ensure perfect lubrication.

The lower end of the piston is formed in the ordinary manner, but it has an elongated portion at its upper end which has an internal and external metallic shell, these two being divided by a layer, or layers, of some material which is a non-conductor of heat, or which conducts it but imperfectly. The interior of the inner shell of the elongated part is open to the interior of the casing which surrounds the crank shaft through an opening in the under-side of the piston; by this arrangement the cooling of the piston is secured.

AN ELECTRICAL CAB SERVICE FOR LONDON.

THE practical solution of the horseless cab problem may now be said to be accomplished. At various times it has been demonstrated that, under certain limiting conditions, electricity could be usefully employed as a motive power for vehicles. Unfortunately, till recently these conditions have been so very strictly limited as to preclude the commercial use of such vehicles. Storage cells were both excessively heavy and easily damaged. They could only be charged at certain secluded spots, usually remote from the area of their use, and they also required a long time in charging. Current, too, was dear, as was the cost of replacing damaged plates in the cells; and so, although it was known that electricity could be most usefully employed in launch and carriage work, yet, owing to the practical difficulties before mentioned, nothing was ever accomplished. During the past few years these difficulties have been lessened to such an extent that electric traction has now become a commercial possibility. The weight of the storage cells relatively to the charge has decreased very much; the cells are now much better, mechanically and electrically, than before, and will stand a good deal of hard use; current can be obtained in a multitude of places, and at a price just one-fourth of what it was less than 10 years ago; while, lastly, the economical employment of that current is also much better effected than was formerly the case. In short, electrical cabs are now possible owing to the improvements that have been effected in storage cells, motors, and in the price of current. In order to take advantage of these improvements the London Electrical Cab Company was formed some nine months ago to construct hackney vehicles propelled by electricity to ply for hire in the streets of London; but as the management of a large number of vehicles could only be economically undertaken by making proper arrangements, considerable time and thought had to be expended in designing a suitable station. We need hardly say that an electric motor-van station is about as much like a stable as a theatre is like a barn. Suitable premises were at length secured at Juxon Street, Lambeth, S.E.—not a particularly pleasant neighbourhood, but one that will no doubt thrive with the new industry in its midst. Juxon Street and its environment somewhat reminds us of Lant Street, Borough—every other house takes in lodgers of a dilapidated kind. Much alteration was needed to render the premises a suitable abode of the horseless cab. The ground floor was made of concrete, and the first floor is built like a gallery (Fig. 6), and is carried on steel joists and columns, leaving a large open space which admits abundance of light and air. On the ground floor is the housing accommodation for the cabs, where they can be cleaned, &c., the alternating dynamos, of which more anon, and a small hydraulic lift. In the gallery above are two pairs of rails about 4 feet 6 inches gauge, on which are trucks. There is also a large switch-board, and from this are led the conductors for charging the batteries.

For obtaining a supply of current the Company could either have put down its own plant or could purchase it from the Supply Companies. Considering that there would be but little economical advantage in having a plant which, even if of sufficient size now, would quickly become too small, and if of large size now would be idle or running light half its time, and also that all Supply Companies find it difficult to increase their day load, the Cab Company decided—and very wisely, we think—to take their current from the Deptford Central Station. As, however, this current is alternating, and reaches the consumer at a pressure of 2,400 volts, it became necessary to put down motor generators which should transform the current to a continuous low voltage one, suitable for charging. At Juxon Street there are two such motor generators, and space for a third.

Each motor generator consists of a Thomson-Houston alternator coupled to a direct current generator. These are mounted on the same bed-plate (*see* Figs. 1, 2, and 3). Each motor has a capacity of 75 kilowatts. The *modus operandi* is as follows:— A battery gives current to the alternator, and when this is at the proper speed, and synchronises with the current in the outer mains (a periodicity of about 80), the latter are switched in; the direct current is then regulated till of the proper pressure for charging. By this method of transformation no secondary or intermediate transformers are necessary. The charging current so produced costs about 1½*d.* per unit.

The cabs are handsome-looking vehicles (*see* Fig. 4), in shape something like coupés. The windows right across the front (which are made to open), and the extra side windows make the carriage very light and pleasant to ride in. They are upholstered in leather, and possess many more small luxuries than the public vehicles now in use—such as the electric light both in the inside and outside lamps, rubber tyres, spring cushions, &c. The driver's seat is in front, but owing to the rounded dashboard the carriages do not have that appearance of being so utterly incomplete without the horse, which might have been expected. Many persons contend that the driving seat should have been at the back, the same as in a hansom, so that the "fare" could have an unrestricted view. On consideration, it will be easily understood that this might be somewhat risky, as the driver of a motor-carriage must be able to see the ground immediately in front of him, especially for traffic in the London streets.

Early experiments made by the Company to determine the energy required to propel the road vehicle on solid rubber tyres, disclosed the fact that the tractive effort on wooden pavements barely exceeds that of a tramcar running on rails,

Fig. 1.—General View of Alternator and Generator.

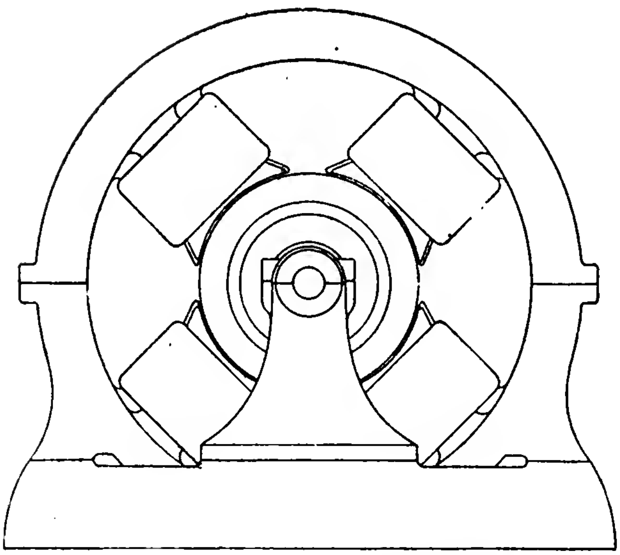

Fig. 2.—End View of Alternator.

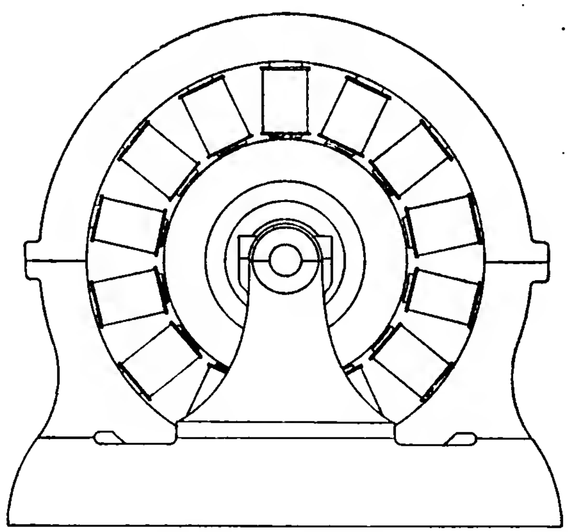

Fig. 3.—End View of Generator or Charging Dynamo.

and even on an ordinary macadamised road the energy taken is not much greater. When, however, the thick mud, such as that met with only in the country, is encountered, the tractive effort is very considerably increased; and this Company, therefore, whilst maintaining that it is perfectly practicable to run electrical vehicles in the streets of London, or other well-paved and comparatively level towns, with commercial success, do not suggest that the same holds good of vehicles to be used on country roads.

has been ingeniously arranged within the gear wheel driven by the motor-pinion and forms a very compact arrangement. The chains connecting the counter-shaft with the driving wheels are of Renold's laminated type.

The battery used on each of the vehicles consists of a set of 40 E.P.S. traction type cells, having a capacity of 170 ampère hours when discharged at a rate of 30 ampères. These cells are all mounted in one tray, which is slung under the bottom of the cab by four suspension links supported by springs under

Fig. 4.—The New Electrical Cab.

The electrical mechanical equipment on each cab consists of a 3 H.P. Johnson Lundell motor with a double wound armature and double wound fields. The series parallel controller by which the connections between the windings of the armature and fields are manipulated is under the control of the driver, and consists of a switch, to be described further on. On each end of the armature spindle is a raw hide pinion which gears into a counter-shaft, which in its turn drives the two driving wheels of the cab through endless chains. As the two wheels are driven by the one motor it was essential to adopt a differential gear of the "Jack-in-the-box" type to connect the two halves of the counter-shaft together. This gear (Fig. 5)

compression, and the ordinary carriage springs again separate the cells from the vibration to which the carriage wheels are exposed. In the case of an electrical cab, such as those now put into service by the London Electrical Cab Company, the accumulators weigh upwards of 14 cwt. out of a total weight, including passengers, of, say, 30 cwt.

It was originally estimated that two sets of cells would be required to enable the cab to do an ordinary day's work in the streets of London, it being considered that one set would propel it about 35 miles. The economy of the motor and controller arrangements, however, is so considerable that it is now found the cabs will do at least 50 miles with one set of cells, and the economy in the use of current thus experienced will make the running of the cabs cheaper than was originally expected.

It being considered that one of the sources of expenditure in the maintenance of traction cells is the amount of pulling about they are usually subjected to in taking them in and out of the vehicles, the cabs have been designed so as to entirely prevent any such damage occurring in their case.

The cabs are placed over an hydraulic table on to which the tray of cells is wheeled on a light skeleton iron trolley. The table is then raised until the tray comes into the position in which it can be attached to the suspending links. The hydraulic table with the trolley is then lowered and the cab left free to propel itself away.

When the cells are to be changed the cab is propelled over the hydraulic table and the reverse operation takes place.

The charging arrangements for the cells are very complete. A battery having been detached from the cab in the manner previously described is run on rails over the hydraulic lift by which it is elevated into the charging gallery (*see* Fig. 6) above. The battery with its trolley is taken on a second trolley along the gallery into its proper charging position where it is connected up to the two conductors through the low tension

speeds allow of the full energy of the current being utilised in the motor without any absorption in resistance, and the cab can thus "crawl" using only about the same number of watts per car mile as when running at full speed. In the reverse direction from the top position the series parallel controller on the first step short circuits the motor through the starting resistance, thereby gently braking the cab. On the second step backwards the motor is completely short circuited, bringing the cab to a dead stop, and the third step backwards reverses the connections between the armatures and fields, all being in series to enable the cab to be moved at the slowest speed backwards. The whole of these movements are produced by the use of one lever placed at the side of the driver's box. The circuit from the accumulators to the controller and motor passes through an ingenious switch arrangement attached to the foot brake which can also be used for bringing the cab to a stop. This switch is arranged to brake the circuit when the foot brake is applied and to brake it rapidly so that there is no injurious arcing at its contacts. It is therefore impossible in the use of either the electric or the foot brake for a careless driver to apply the brake whilst the current is still passing through the motor. The foot brake has another advantage in the crowded London

FIG. 5.—THE ELECTRICAL CAB COMPANY'S DIFFERENTIAL GEAR.

supply. One of these conductors passes directly back to the charging switchboard through a regulating resistance and ameter, the other conductor being attached to a common return. Each battery is, therefore, separately connected to the charging switchboard and the charging current regulated by its own regulating resistance switch. The cells on which these switches are mounted are also used for registering the time at which each battery is put on to the charging circuit and the rate at which it is being charged.

The double wound motor and series parallel controller is perhaps the most important arrangement on the cab, ensuring, as it does, the greatest economy in the consumption of current at whatever speed the cab may be running. The controller is arranged so as on the first step to connect on two armature windings and the two field windings of any series with a small starting resistance—this is not a running speed but is only intended to start the motor into motion. On the second step the windings are still in series but the resistance cut out, and with this arrangement the cab runs at a speed of about three miles an hour. The third step places the armatures in parallel but leaves the fields in series, and with this arrangement the cab runs at about seven miles an hour. The fourth step places the field windings in parallel and the cab runs nine miles an hour. It will thus be seen that three normal running

streets, for when moving in a block the driver can set his controller handle to slow ahead and then start and stop the cab time after time as the traffic slowly moves on by simply putting on and taking off his foot brake.

It may be here pointed out that the stopping of these electrical vehicles is far more under control than any horse-driven carriage, a fact we have demonstrated for ourselves. Not only is it fitted with a much more powerful brake, but the driver can readily reverse the action of the motor, and there is, of course, no horse slipping.

A special plug or key is in the possession of each driver; without this key it is impossible for anyone to move the carriage. When leaving his seat the driver simply places the key in his pocket. The advantages of this are obvious.

The steering and driving of the cab is simplicity itself, and requires no skilled knowledge whatever. Out of 15 hansom cab drivers who were tried, it was found that 12 within two days were quite capable of guiding the vehicle in any traffic.

On the left hand side of the driver's seat is a lever handle; the carriage commences to move immediately this handle is pushed forward, and the more forward the handle is moved the faster moves the vehicle, from one mile to 10 miles an hour. Reversing the handle simply means making the carriage go slower, and when reversed beyond the stationary point the carriage commences to go backward. The driver's right hand is occupied by moving a little wheel, which steers the vehicle in any direction. The brake-power is applied by the driver's right foot; directly this is applied the electric current is cut off, so that there is no energy acting against the brake.

Although they had declined to grant licenses to several other kinds of motor-carriages, which licenses had previously been applied for, the Scotland Yard authorities unhesitatingly agreed to give the necessary license to these cabs, subject to the sensible restriction that each vehicle should be accompanied by its driver, who was required to prove that he was capable, not only of guiding the carriage, but of turning it in a very small space, and of stopping it immediately when required. These tests were satisfactorily fulfilled.

The inauguration of the new cab service took place on August 9th, when, on the invitation of the directors of the Company, a large and distinguished body of guests, including many of the prominent members of the turf, electrical, and journalistic professions, assembled to inspect the new vehicles. The proceedings were fully described in the daily papers, and so we need not refer to them any more than to say that an interesting feature was an address by Mr. W. H. Preece, F.R.S., who said it was some gratification to him to be called upon to come there and inaugurate such a great and interesting undertaking. He knew nothing about these electric cabs until last week, but since then he had had many pleasant drives in them, to the amusement of the omnibus drivers, but, he feared, also to the chagrin of the cab drivers. There was a strange fascination about electricity. It was true there was a "cussedness" about it, in that it had a knack of doing that which was least expected, but at the same time he had always found that it never failed to do what might be fairly expected of it when it was carefully handled. He had great faith in electricity as a mode of traction. The horse was a most imperfect machine; its principles were horrible to the engineer. It moved in unstable equilibrium, and sometimes got a bad fall in consequence. Then it was unmechanical in its movements, and was very weak in its head, for if it got frightened, or mentally disturbed, God alone knew what it would do. They had seen only the previous day a horse run into a post office in the City, presumably for peace and quietness, yet every Londoner knew that the very last place where he might hope to find peace and quiet

FIG. 6.—THE ELECTRICAL CAB COMPANY'S CHARGING STATION.

was in a post office. Then the horse must be well fed. It was subject to disease as we were, and it was very much shorter lived. The driver must constantly be thinking of his horse, and if he did not it very soon came to grief; indeed, they both frequently came to grief together. Still, they must all love the horse and care for it in the best way they could, but at the same time it was decidedly necessary to see whether they could not find another and more perfect way of doing its work. Then, again, the horse wanted special accommodation, yet when they looked around them in the building they were in to-day they would find room for 50 cabs, whilst the horses were put in the gallery and wanted no food at all. People would, doubtless, stick to the horse for what it was worth until the question of economics came in, and the electric motor applied itself to the work economically and efficiently with almost human power of discrimination. It was ready for work under all circumstances. The motor was self-regulating; the energy expended by it varied exactly with the work it had to do. It puts its shoulder to the wheel when going uphill, and not only applies a brake when going down hill, but that very action serves to restore the energy taken from it. In that respect it was decidedly unique. Fourteen years ago, in Vienna, he had ridden an electric cycle. Mr. Volk, of Brighton, had also experimented with an electric dog-cart. Then we had recently had occasional glances at an electric omnibus in the streets of London, and he had ridden in a very successful and comfortable little carriage in Wolverhampton, built by Messrs. Elwell, Parker, and Co., and the demonstration to-day was the summit of their efforts, and what they were doing here was also being done in Paris, New York, and Chicago. But all their success with electric carriages depended upon the cells, and improvements in the accumulator had been a very powerful factor in their development, as well as improvements in the batteries employed for supplying the necessary energy. The accumulator itself had made a progress that was simply marvellous. In 1881 it required 300 lbs. weight to absorb one Board of Trade unit or kilowatt hour, for which now only about 100 lbs. weight was needed. In this respect there was, however, room for considerable further improvement, and although they had been able to reduce the weight of the accumulator to one-third of what it was before, they were still hoping for something better. The cabs of the Electrical Cab Company carried 40 cells, absorbing 16 units. The currents they used were alternating currents generated at Deptford, and changed into continuous currents in the building they were now in, and the batteries were charged in the galleries above. There was very little loss on the whole, and a set of accumulators on being charged would suffice to drive one of the cabs a distance of 50 to 60 miles—that is to say, one unit of power would drive the car about four miles. The cost of the electricity was only 1½*d.* per unit; in other words, 2*s.* per day, or ·35 of a penny per mile. For current the Company had contracted for regular supplies at a fixed charge of 10 per cent. for maintenance. They had met there that day to set the new movement going. He hoped to see charging stations everywhere throughout the city; indeed, at every cabmen's shelter. They would then be able to see what was the durability of the cells. He had himself an absolute belief in the power of electricity as the ultimate motive agency. He was pleased to think that the problem would now be satisfactorily elaborated, and he wished the Company every success.

Mr. W. C. Bersey.

Mr. H. H. Mulliner (the Chairman) said he had been pleased to hear Mr. Preece's remarks, and to find that he thought so well of the electric cab. At the same time he would like to say that the principal credit of what they had done was due to Mr. Brougham and Mr. Bersey. They would now show those present the practical working of the cabs, and he would first explain that in placing them upon the streets the price of hiring would be the same as for ordinary horse-drawn vehicles. The cab drivers were, in fact, their best friend. They had had large numbers of applications from cab drivers to be taken on as drivers of their vehicles, and they had found no difficulty in teaching them readily to handle the cars. He proposed a vote of thanks to Mr. Preece for what he had done for them that day.

At the conclusion of the formal proceedings, the cabs were placed at the disposal of the company, and many of those present availed themselves of the opportunity afforded them to indulge in a ride and test the capabilities of the vehicles. The route selected was over Westminster Bridge and through the heavy traffic to Charing Cross. The appearance of the cabs, the wonderful ease with which they were controlled, the smoothness of their running, excited universal admiration. We have no hesitation in saying that the best appointed horse-drawn carriage is simply not in it with these electrical cabs. Their design and workmanship leave little or nothing to be desired, and the greatest credit is due to Mr. Manville, the consulting engineer, and to Mr. Bersey, the manager, for producing such faultless machines. Already the Company has been overwhelmed with applications from people usually designated as "carriage folk" for the hire of the cabs for the next London season. Indeed, out of the 15 cabs present on the opening day, 13 were at once hired for terms varying from a month upwards.

There is, of course, the vulgar opposition of the horsey people, but this so far has confined itself to that particular form of humour peculiar to those who drive horses. The electrical cabs are being turned out as fast as possible, and within the next few months there will be nearly 100 plying for hire in London. It only remains for us to congratulate the Company upon the splendid success which has attended this experiment in automobilism.

Mr. J. W. Barnard, Secretary to the Electrical Power Storage Company, writes :—

"I am instructed by my directors to call your attention to the fact that the storage battery which has rendered possible the solution of the problem of electric traction on common roads, and which is being used by the London Electrical Cab Company for the propulsion of their vehicles, is the practical result of patented inventions, the outcome of the 16 years' experience of this Company and its staff.

"It may further be a matter of interest to the public to know that the battery is manufactured in London, giving employment to a large amount of British labour."

The *Daily News* of the 8th instant says :—"Motor-cabs are certainly finding general favour, and there are now 17 of them running in London. There have been eight out on the ranks this week, and by Monday there will be 12. By the end of next week the Company expect to have altogether 25 of the new vehicles, and after that a further order for 50 cabs now in hand should give them about four additional ones every week. Scotland Yard, of course, examines and tests every vehicle before licensing it, and one of their tests is to make each driver take his cab up and down the very sharp incline in the Savoy between the Strand and the Embankment. With regard to the cabdrivers' protests against the new introduction, there is certainly less occasion for it than is ordinarily the case where mechanical inventions are first introduced. We are assured that every driver thus far employed is an old cab-horse driver, and that the cab washers are all taken from cab-yards. The men for whom no place can be found in connection with motor-cab service are the horsekeepers. Their places must inevitably be taken by engineers' fitters. That is unfortunate, but it cannot be helped, and no very considerable number of men at a time are likely to be thrown out of employ, and though, of course, it intensifies competition for employment, the occupation of horsekeeper is, of course, in considerable demand in other ways."

Zola on Automobilism.—The great French realistic writer, Emile Zola, writes to *Les Sports* to the effect that he is a partisan of the automotor, and is convinced that the horse will exist only as a curiosity when the practical electric motor is found. The advantages of the automotor are incalculable ; it is an instrument of civilisation and fraternity.

THE AUTOMOTOR INDUSTRY.

The Daimler Company's Works.

Coventry may be said to be the home of light machinery construction, and whether for watches, cycles, or motor-cars, the legend that a machine is "made in Coventry" is at once a guarantee of fitness and excellence. Coventry cycles are known all over the world and command the best prices, and from the manufacture of cycles to that of motor-cars is but a step.

Fig. 1.—Daimler Motor (Front View).

Indeed, the mechanical instinct seems to be a distinguishing feature of the Coventry people, and no doubt dates from the time when a citizen, somewhat harshly described by the late poet Laureate as a "low churl," "bored a little augur hole in fear," in order to obtain a view of Lady Godiva under circumstances known to most people—at any rate in Coventry, where that lady's name is still very properly venerated. Whether this theory is correct or not is immaterial, the fact remains that skill in the construction of light machinery is hereditary with most of the inhabitants. When, then, the Daimler and other motor manufacturers selected Coventry as the scene of their operations they showed wisdom.

The Daimler motor was originally a German invention, and was the outcome of much labour and experiment on the part of an engineer of that name who assisted Dr. Otto in the perfection of the gas engine.

Fig. 2.—Daimler Motor (Plan).

The Daimler motor of the standard type is a two-cylinder vertical engine using light petroleum as the motive power and working on the Otto, or more correctly the Beau de Rochas, cycle. The cylinders are 80mm. in diameter by 120mm. stroke. The engine runs at about 750 to 800 revs., and gives off about 3½ to 4½ H.P. It is, in proportion to its power, an exceedingly light and compact motor, weighing but 325 lbs., and has shown itself admirably adapted for motor-cars, launches, &c.

The general arrangement of the motor as applied to cars is shown in Figs. 1, 2, and 3, which are respectively a front view, plan, and side view of a motor mounted on its frame but without the body. It will be seen that the shaft of the motor is placed longitudinally, and hence its motion has to be transmitted to the second motion shaft by bevel gearing. Like all motors working on the Otto cycle it is uni-direction, and hence the reversal of the driven shaft has to be accomplished by means of gearing, as has also any variation in the speed. All this gearing is cased-in as seen in plan and runs in a bath of oil.

The second motion shaft drives the rear wheels by means of pinions and chains, the usual differential gearing being interposed. Although the number of working parts is large, and at first sight the gearing may appear to be complicated, yet in practice this has not been found to be a disadvantage, and ordinary drivers with no mechanical knowledge find no difficulty in handling these cars. At the rear of the frame are the oil and water tanks, both having a capacity sufficient for a 50-mile run. The various types of motor-cars manufactured by the Daimler Company are shown in Figs. 4

Fig. 4.—Daimler Crawford Waggonette.

Fig. 3.—Daimler Motor (Side View).

to 8—Figs. 4 and 5 being a Crawford wagonette with the hood up and down; Fig. 6 is a Rougemont car; Fig. 7 is a tradesman's van, several of which are in use; and Fig. 8 is a latest pattern parcel van driven by a four H.P. motor.

The Daimler Company does not, however, confine its operations only to motor-cars, but manufactures motors for launch and small craft propulsion. For river work and yachting purposes an oil launch is well suited, being at once clean, compact, and light. In these small vessels the reversing is effected by means of bevel friction gear. In Figs. 9, 10, and 11 we illustrate the usual type of Daimler launch, such as is supplied to the harbour and river authorities, and which is largely used up the Thames and on the Scottish lochs.

Fig. 9 is a longitudinal fore section, Fig. 10 fore-deck plan, and Fig. 11 a midship section. These launches are built in any desired way, either for sea or river use. For the former they are made fuller in their lines, and are partially decked, so as to enable them to stand a choppy sea. The engine is also cased in and is of a more powerful description. For river work a light construction is permissible with fine lines, and hence a good speed can

Fig. 5.—Daimler Crawford Wagonette.

be obtained with very little expenditure of power. The propellers are of brass or manganese bronze, and are carried in the usual way. For the larger craft reversing can be effected by adopting a reversing pitch propeller, which is worked through a rod passing through the hollow main shaft, but for small craft the bevel friction gear, as seen in Figs. 9 and 10, answers admirably. The method of working these engines is as follows:—

Referring to the drawings, the pressure valve, G, which is actuated by the exhaust forces the oil fuel for supplying the motor from the tank, B, to the vaporiser, C; this valve also supplies oil to the ignition burners, D, and hence a continuous supply is maintained when the motor is running. In starting the motor the initial pressure of oil is obtained by means of a hand air-pump forcing air into the tank, B, through the inlet cock, H.

Fig. 6.—Daimler Rougemont Car.

The explosive charge in the vaporiser, C, is obtained as follows:—During the downward stroke of the piston air and petrol are sucked in and mixed, this mixture of air and oil vapour passes into the ignition chamber, the necessary proportion of air and oil being maintained by the inlet jets being suitably adjusted. The petrol is always maintained at the required level by means of the float valve in chamber E.

Before starting the motor the ignition tubes must be heated to a bright red by the burners, D, which must be lighted up by means of the methylated spirit heater. With motors using ordinary petroleum a small saucer is provided underneath the burners to obviate the use of the torch. This saucer should be filled with methylated spirit, which must be allowed to nearly burn out before applying the pressure from the hand air pump. This done, the petrol passing through the heated burner tubes becomes vaporised, and the flames burn briskly with a blue-green tint. If the flames spit, flare, or burn a yellowish colour, this indicates that the burners are not sufficiently heated. In the case of petroleum motors it is requisite to heat the vaporiser as well as the burners before the motor can be started. This takes about 10 minutes, and is best done by means of a brazier's lamp. During the running of the motor the vaporiser is automatically kept up to the necessary temperature by the exhaust.

The ignition tubes being red hot (and with petroleum motors the vaporiser is sufficiently heated) the motor can be started. To do this, press down the rod, W, and give the crank handle, L, one or two turns (after pushing in the starting tongue in axis of same), when the first charge will be drawn into the ignition chamber and fired. The motor will then run at full speed without further assistance. Before starting the motor the reversing lever, M, must be placed in the central notch, in which position the propeller shaft is disconnected from the motor. By moving lever forward the propeller is connected, and the launch will move ahead. By moving the lever right aft the reversing gear is brought into operation, and the launch will go astern. By drawing up the rod, W, the valve rods are thrown out of gear and the supply of oil to the motor cut off, the burners being still fed. By opening the air cock, U, the pressure in the tank, B, is released and no oil flows to the ignition tubes; the flames are then extinguished.

Although from this description it may appear that these motors require a certain amount of skilled attention, yet such is not the case. Ordinary watermen after a few lessons find no difficulty in manipulating them.

The Company's works are situated at Coventry, and comprise a very large well-lighted factory with offices and stores. The works have railway sidings running into them, and are, moreover, close to a canal, and hence raw material and finished pro-

Fig. 7.—Daimler Tradesman's Van.

ducts can be handled with the least cost. The factory is extremely well arranged, and as far as possible all operations are consecutive—that is, the raw material goes in at one end and comes out at the other manufactured into motor-cars, &c. The character of the machinery will be gathered from the accompanying engravings. Fig. 12 shows the brass turning shop; Fig. 13 is the light machine shop. There are some eight separate shops altogether, all equipped with the latest and most expensive machinery, mostly, as regards lathes, of

American make. When we say that some £20,000 has been spent in plant alone it will be seen that the Daimler Company has laid itself out to do a big business. One of the most interesting shops is shown in Fig. 14, which is the engine erecting and testing shops. Here the motors are subjected to a prolonged testing on the brakes. As will be seen, very complete arrangements are made to ensure this being properly and systematically done. Iron standards are placed at intervals and to these the motors are bolted. Some 20 machines can be tested at once. Fig. 15 is the carriage erecting shop, and like all the others is large and spacious, being 130 feet by 120 feet. At the time of our visit there were some 50 motor-cars under construction and orders were plentiful. We observed that in the Daimler factory the metric system prevails, all measurements being in millimetres. It will thus be seen that Mr. J. S. Critchley, the manager, is quite ahead of the latest engineering practice. With the magnificent plant the Company possesses it deserves every success, and the busy appearance of the works gives ample evidence that this is being achieved; some 250 men are employed, and already the Company is talking of extension. Its motors are well known and have stood the test of hard use. As is well known, it was the Daimler motor that gained the first place in the Paris-Marseilles Competition of 1896. In conclusion, our visit was undertaken for the purpose of seeing what was being done in the motor-car industry. We saw everything that was necessary to convince any unbiassed person that the Daimler Company is carrying on a large business in the manufacture of motor-cars.

The Press on Motor-Cars.—The Institute of Journalists—a somewhat hybrid body—has lately been holding its Congress at Cardiff, and we observe from the proceedings that much of the usual gush was indulged in about the "formation of public opinion," "independent judgment," "freedom of thought," and so forth. We do not dispute the general proposition thus advanced, but,

Fig. 13.—Daimler Company's Light Machine Shop.

FIG. 14.—DAIMLER COMPANY'S ENGINE ERECTING AND TESTING SHOP.

on the contrary, have some vivid recollection of what the "formation of public opinion" by the (from a professional and technical point of view) uninstructed writers in the daily Press means. Before the Jubilee the Press warned the public of the dangerous crowds, the risk of fire, the absence of food that would be features of that aupicious day. There was not the slightest ground for this old woman's claptrap from Fleet Street. Yet the public believed it, with the result that there were no crowds, no fires, and food was so plentiful that it was thrown away by the ton, and those who had looked forward to making a legitimate "thing" out of the Jubilee, such as by letting seats, &c., lost heavily—not that we feel at all sorry for them. Similarly, as regards motor-cars. When the Brighton affair was on, and, like all things, was duly off, the Press went into hysterics, and cab and omnibus proprietors contemplated bankruptcy, farmers and carriers looked at their horses and softly recited that poem beginning, "My beautiful, my beautiful, that standest meekly by," &c., &c. They thought because the Press had said so that horses would be useless. Of course this was utter nonsense, but still there *was* a slump in horseflesh, because the Press had taken an utterly wrong view of the question. We then gradually descended from the *L'Allegro* attitude to the *Il Pensero* of utter depression, consequent upon the failure of *The Engineer* competition and the "pessimistic" (good word that) attitude of the daily Press. The worthy proprietors of Aldridge's and Tattersall's took heart once more, and with much thankfulness carried on their business again. We now have the chorus of approval and sanguine anticipation on the part of the daily Press as a result of the successful inauguration of the electrical cab industry in London, and omnibus drivers and "kebmin" are again given over to the most gloomy views of the future. Now no one has greater faith in automobilism than ourselves, and no one more cordially detests the horse for urban traffic than we do, yet, supposing for the moment that by this time next year all cabs and omnibuses would be mechanically propelled, horse property would be

FIG. 15.—DAIMLER COMPANY'S CARRIAGE ERECTING SHOP

2 L 4

as good an investment as ever. But all history shows that changes are not lightly made in the habits of people, and motor-cars have to win public approval just in the same way as did steamships, rifled guns, silk hats, rational dresses, and other things. Our point is, that the public should not heed to any extent these predictions of the daily Press, because those who utter them are not either in the position to know what is being attempted or competent to pass judgment on mechanical matters.

AUTOMOTORS AT THE AGRICULTURAL HALL.

At first sight the connection between laundries and automotors is not very apparent; yet, as the family wash is usually brought home in a van, and as, for hygienic and sanitary reasons, an automotor is preferable to any horse-drawn vehicle, it is evident that clean linen is better carried in an automotor than in an ordinary horse-drawn cart. Hence the spirited proprietors of our contemporary, *Industries and Iron*, Messrs. Cordingley and Co., so far from doing anything incongruous, as some writers in the daily Press have suggested, displayed sound common sense in associating laundry machines and appliances with motor-cars in one exhibition. With the former we need not concern ourselves further than to remark that every year washing clothes, one of the most unpleasant domestic duties, is rendered less so by the many labour-saving appliances that are from time to time introduced. In spite of all these, however, laundry work demands considerable muscular effort, and is not much liked. A dearth of labour seems to be the general complaint on the part of those who manage laundries, and it is rather surprising to learn that at the present moment work could easily be found in London for at least 5,000 ironers at good wages. At the Agricultural Hall many fine examples of washing machines were to be seen. Coming to the motors, most of the leading makers exhibited. The London Electrical Cab Company showed three of their vehicles, which were universally admired. The London Motor Van and Wagon Company have made the construction of light vans a specialty, and had three good examples on view, one being the "Harlene" van, which has been running in London for over two months with the most satisfactory results. Another one was a light canvas-covered van, very suitable for laundry purposes. It is propelled by an oil-motor of the British Motor Syndicate type, which gives off from 4 to 4½ B.H.P., the total weight of the van complete being 18½ cwt., and the carrying capacity being about the same. Four speeds are provided, ranging from 3 to 12 miles per hour. The Daimler Motor Company showed two specimens of their handiwork, in the shape of a Knightley carriage and a Siamese car. The former is a four-seated phaeton, and is propelled by a 4½ B.H.P. Daimler motor, the speed attained being, we were informed, 17 miles per hour. The latter is similar to the former, save that the body of the car is detachable, and either a phaeton or van body can be fixed at will. This system of having two car bodies and one motor frame has much to recommend it, and is decidedly novel. An enterprising tradesman could thus use his motor-van for business in the week, and as a carriage on Sundays and holidays.

The Great Horseless Carriage Company showed two Bollées, or, as the firm prefer to call them, Coventry Motettes, and two vans, having Daimler motors. Indeed, the exhibition was mainly confined to motors of this make. The Hon. C. S. Rolls showed his Peugeot phaeton, which has done a lot of travelling in its time, and looks as if it needed renovation. We regret that neither Messrs. New and Mayne, Messrs. Roots and Venables, the Lifu Company, Thornycrofts, nor the Anglo-French Company exhibited. It was anticipated that there would have been at least 30 cars, but on the occasion of our visit we could only count 12. As an exhibition of motor-cars it must be pronounced a failure, and we cannot understand the attitude of non-exhibitors.

CABBY'S FAREWELL TO HIS STEED.

The *St. James's Gazette* publishes the following pathetic poem:—

So long, old 'oss; you're jest played aht, you've taken you're last fare,
Your quarters are the knacker's nah, and mine are Lord knows where;
There ain't no room in London nah for either you or me,
We're crahded aht by cabs as go by electricitee.

It warn't all beer and skittles, even in the palmy days,
What with the cove with principles, his legal fare as pays;
But when the "biz" was pretty brisk, and cabby got the pull,
I could plank dahn for the Derby on my fancy 'arf a bull.

It's nuts, it is, on some fine day, to pick up some young nob,
And drive 'im all the morning till the fare is nineteen bob;
And then he stops at Gresham 'Ouse, and shahting "Cabby, wait,"
'E takes 'is 'ook the other end aht into Bishopsgate.

Or on a lovely autumn when the rain came dahn in sheets,
Or when a bloomin' blizzard set us skatin' in the streets,
And after yon 'ad planked dahn to the yard each bob you 'ad,
And fahnd yerself to balance up a dollar to the bad.

Then to take yer to the stables at the other end of tahn,
And strip yer frozen 'arness off, and rub yer old 'ide dahn;
And yer got yer jolly skin full, and a decent place to doss,
Which was often more nor *I* got by a jolly site, old 'oss.

But nah—so long, my beauty; for this latest style I bar—
I ain't a going (what do *you* think) to run a motor-car;
While there's a crossing to be swept, a job to do—no fear—
I reckon I'm too old to turn a blooming engineer.

Municipal and County Surveyors, Please Note!—According to two distinguished French cyclists who have been touring throughout Europe, including our own country, the roads in England are the worst maintained of any and the most impracticable in Europe, and, worse still, the inns are no better than the roads. A criticism we venture to say severe but not altogether untrue.

Some Useless Automotors.—The Admiralty have decided that all Whitehead torpedoes of Mark I (Star) and Mark II (Two Star) are to be at once destroyed, together with all their fittings. There are about 300 of these torpedoes in the service, and although they cost about £500 each, the Admiralty have been compelled to condemn them in consequence of the unfavourable reports that have been made as to their erratic movements after firing.

An Indian Prince at Coventry.—Last month His Highness the Marajah Thakore Sahib, of Morvi, visited Coventry for the purpose of inspecting the Daimler Motor Works, His Highness being interested in light railways for the development of his own country in North-West India. He arrived at Coventry from Birmingham, accompanied by Mr. F. H. Gill, M.I.Mech.E., who is connected with a firm that has put down 150 miles of light rails for the Prince, who is interested in motor-driven vehicles, and is taking advantage of his visit to England to learn what he can on the subject. On arriving at Coventry he was driven in a motor-car by Mr. Critchley, of the Daimler Company, to the King's Head Hotel, where luncheon was served, and he afterwards proceeded to the Company's works on the Foleshill Road. The whole of the afternoon was spent there, the Prince manifesting an intelligent interest in the details of motor construction. He left Coventry in the evening.

STEEL TRAMWAYS FOR ROADS.

THE American correspondent of *The Engineer* writes to his paper:—"One of the suggestions which has been put forward by the Road Inquiry Bureau of the Government, is that steel rails should be laid along country roads, so as to reduce the tractive effort required, and therefore enable farmers and other carriers to haul very much heavier loads than are practicable on ordinary country roads. The idea has obtained some foothold, and a special section of H-beam or rolled joist—having a wide and slightly concave top flange—has been recommended as the most suitable form, having enough rigidity to keep the trackway in fair level, the rails being connected by tie rods or tie bars. This form of section, however, has not been adopted by the Bureau, and it proposes a rail of inverted trough section, having a slight rib along the inside edge of the top, the metal being $\frac{7}{16}$ inch thick, and the width of tread 8 inches. The rails are to be bedded in gravel laid in well-drained trenches, and to be connected by rods at the middle and ends. The joints will probably rest upon saddles in order to prevent low joints, and each joint would form a 'rerail,' so as to put wheels on the rail, and so prevent the formation of ruts alongside the rails. It is claimed that with such a track the traction will be reduced from 40 lbs. per ton on macadam to 8 lbs. per ton on the steel roadway. The weight of material would be about 100 tons per mile, costing £400 to £700 per mile, according to the size of the contract. A lighter type of track could be built with 50 tons of steel per mile at a cost of about £200 per mile. These prices are for material only, exclusive of trenches, gravel, and construction. In view of the agitation in Great Britain for greater traffic facilities for the agricultural districts, it might be interesting to enquire whether such a system as this might not be applicable in some districts where even the 'light railway' has not penetrated, but where greater facilities are desired."

AN AMERICAN ELECTRIC CARRIAGE.

As will be gathered from the accompanying drawings, the electric brougham of Messrs. Morris and Salom, of Philadelphia, is a remarkably handsome and well-designed affair, embodying as it does the best taste and workmanship. It forms one of the automotor cabs now plying for hire in New York city, and it will be interesting to compare it with the electrical cabs now running in London, and which we illustrate on p. 485. Referring to the American design (Fig. 1), it will be seen that the vehicle consists of a carriage body and boot, the latter containing the battery of secondary or storage cells. It will be noticed that the body is slung rather low—a point which is of advantage to elderly people, but which in a very slight degree tends to rolling. We may as well here state a fact which, so far as our experience goes, but few carriage builders are aware of, that for smoothness of running a high centre of gravity in any vehicle is necessary—*pace* the fast express engines on the American and English roads. It will also be noticed that the fore wheels are larger than the rear ones, and that the former constitute the driving wheels, and the rear wheels the steering ones. Thus in these important points, we see what we may reasonably regard as the best American practice is utterly at variance with the best English and Continental practice. Both cannot be right, and, in our opinion, from a scientific point of view, the American design in this particular is faulty. In other respects the design has much to recommend it. The carriage itself is comfortable and well upholstered, and will carry two persons. In Figs. 2, 3, and 4 we give respectively an elevation, underneath plan, and front view of the car. It will be seen that the latter is supported on plate springs which are connected in the usual way to the axles. The wheels are of the pneumatic bicycle type, the fore ones being 36-inch diameter and the rear ones 32-inch diameter, the spokes being $\frac{1}{4}$-inch steel wire; the tyres are 3-inch Harford's, $\frac{1}{2}$-inch thick rubber, and are inflated under a pressure of 80 lbs. per square inch. Steering is effected by a system of rods, &c., terminating in the handle, F

FIG. 1.—MORRIS AND SALOM'S ELECTRIC CARRIAGE.

FIG. 2.—MORRIS AND SALOM'S ELECTRIC CARRIAGE.

FIG. 3.—MORRIS AND SALOM'S ELECTRIC CARRIAGE.

(Fig. 2), this being its normal position; when pushed forward to G the vehicle goes to the right, and when pushed back to H, to the left. We cannot say that this strikes us as being a commendable arrangement. It is not a positive gear; the direction in which a starting lever or wheel is moved should always indicate that in which motion is to be made. A driver who lost his head in a crowded street would probably do some damage with this steering gear. The motive power is furnished by a battery carried in the boot, L (Fig. 2). This battery consists of 44 cells of the type 3 F of the Electric Storage Battery Company; the current passes into the two Lundell motors. These are series-wound machines and weigh about 150 lbs. each. On each armature spindle is a pinion which

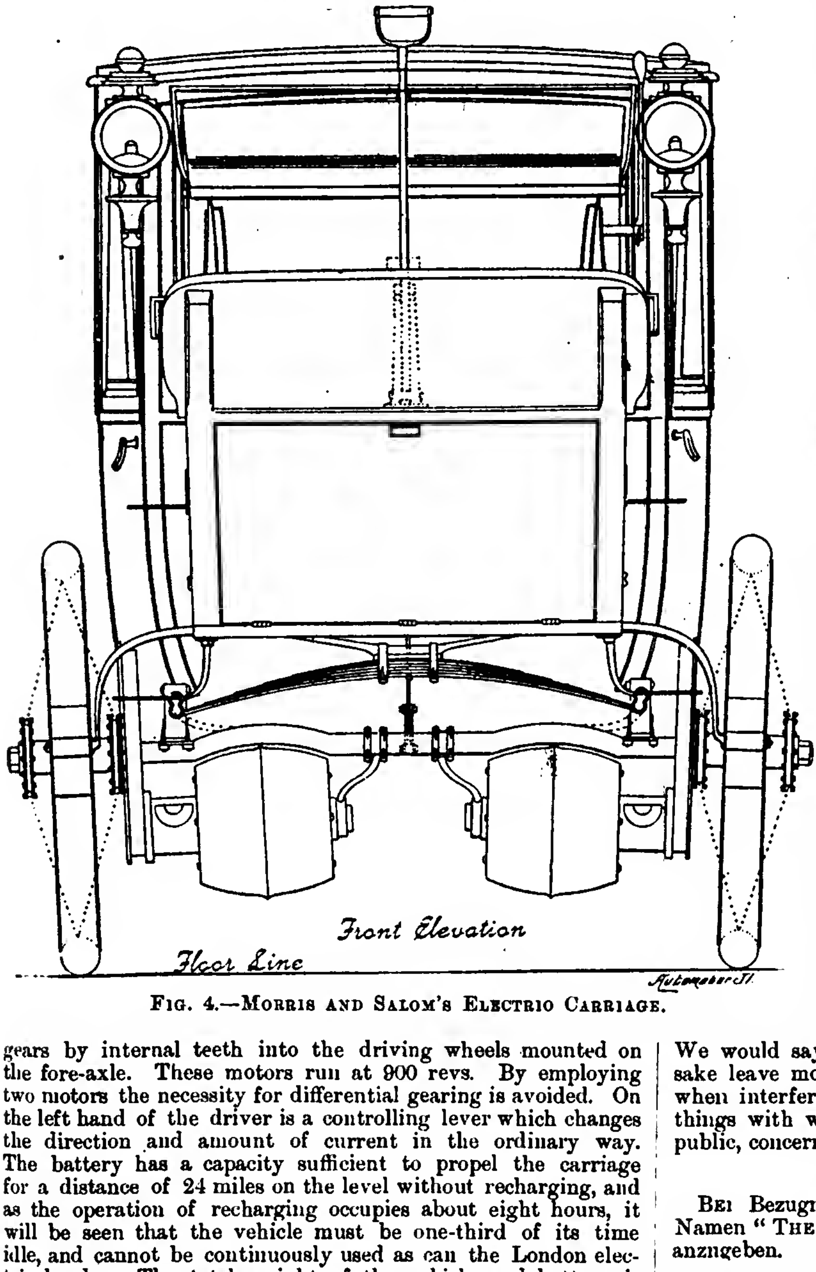

Fig. 4.—Morris and Salom's Electric Carriage.

gears by internal teeth into the driving wheels mounted on the fore-axle. These motors run at 900 revs. By employing two motors the necessity for differential gearing is avoided. On the left hand of the driver is a controlling lever which changes the direction and amount of current in the ordinary way. The battery has a capacity sufficient to propel the carriage for a distance of 24 miles on the level without recharging, and as the operation of recharging occupies about eight hours, it will be seen that the vehicle must be one-third of its time idle, and cannot be continuously used as can the London electrical cabs. The total weight of the vehicle and battery is about 2,600 lbs., of which the battery accounts for 1,000 lbs. Of this total weight two-thirds are on the front wheels and the balance on the rear wheels. This distribution of weight is not in our opinion proper, and we expect that this will be found to be the case in practical work, especially in hill climbing. The performances of these cabs, of which 100 are, we understand, on order, will be watched with interest, and it will be instructive to learn which is the more economical in working—the New York or London ones.

PETROLEUM AND MOTOR-CARS.

Our contemporary, *London*, publishes the report of the chief officer of the Public Control Department of the London County Council under the ridiculous and sensational headline, "Death in Lamp Oil." By the way, why cannot the organs of municipalisation, such as *London* and the *Daily Chronicle*, employ a more sober style? Half the good that these papers undoubtedly do is marred by the adoption of a shrieking, emotional method of treating affairs. This kind of thing may no doubt appeal to many, but it hardly commends itself to those who have any pretence to common-sense or sound judgment.

On the question of motor-cars, the report says:—"The Locomotives on Highways Act, 1896, received the Royal Assent on August 14th last, and came into force on November 14th, 1896. This Act relaxes the restrictions of previous enactments on the use of locomotives on highways so far as they relate to vehicles propelled by mechanical power and under three tons in weight unladen, and not used for the purpose of drawing more than one vehicle (such vehicle with its locomotive not to exceed in weight unladen four tons). Section 5 of the Act provides that the keeping and use of petroleum or of any other inflammable liquid or fuel for the purpose of light locomotives shall be subject to regulations made by a Secretary of State, and regulations have been made which provide that a motor-car may carry 40 gallons of petroleum in two metal tanks, each containing not more than 20 gallons. There is no obligation on the part of owners of motor-cars in which petroleum spirit is used to notify the local authorities that they keep petroleum for use in such motor-cars, nor is power of inspection given to local authorities to see that the regulations are complied with. As the absence of these provisions rendered it difficult to satisfactorily enforce the regulations, the Public Control Committee asked the Home Secretary to consider these points whenever the amendment of the regulations was contemplated. The Home Secretary has expressed his agreement with the Council's views, but as the number of motor-cars using petroleum is inconsiderable, he is of opinion that the necessity for the suggested amendment does not present itself yet, and the experience of this department is quite in accord with this view." We would say to the London County Council, For goodness sake leave motor-cars alone till they become a public danger, when interference would be justifiable. There are many more things with which the Council might, with advantage to the public, concern itself than motor-cars.

CONTINENTAL NOTES.

We note that the Government of the Duchy of Luxembourg has concluded an arrangement with M. Scotte for the use of his trains in the Duchy.

MM. De Dion et Bouton have dispatched an omnibus tractor which will haul another omnibus for service in Geneva and the neighbourhood.

The Paris Cab Company are contemplating how they can transform their cabs into motor-cars. They prefer electricity, but are trying other systems.

We notice that automobilists in France as in England complain bitterly of "Policemanism." It is time that concerted action was taken to abate this nuisance.

It is curious that neither in Berlin nor Vienna has automobilism caught on. In the former city a solitary motor-car is occasionally to be seen, and there are four or five in the latter.

A motor-car race for amateurs took place on August 30th. The course was from Carcassone to Perpignan, a distance of 120 kilometres. It was organised by the Société des Chauffeurs du Midi.

In Belgium a recent police regulation prohibits the driving of motor-cars by persons less than 18 years of age, and in Brussels a motor-car must not go at a speed faster than a horse can trot.

The Compagnie Générale des Automobiles is making experiments with a new rotary motor on the epicycloidal system, the invention of a M. Valentin. The results are said to be satisfactory.

An enterprising French gentleman, M. Sevin, has started a school of automobilism for giving instruction to coachmen and others. The idea seems a good one, and we hope it will meet with success.

The Northern Railway Company of France are making exhaustive trials with three motor-cars. One is a Serpollet, another a Panhard, and the third an electric car made in their own shops. It will be interesting to know the result.

We are glad to observe that the French coachmen take a much more sensible view of the introduction of automotors than do their English colleagues. The French Cabmen's Union declares that automobilism will be the making of the Union.

The French Post Office is about to use electrical automotors in place of the four-wheeled carts. The head office at Paris has an electrical installation, and so charging could easily be effected. The new mail-carts will go 20 kilometres without recharging, and carry 800 kilos. of parcels.

The English visitors to the Paris-Dieppe race will learn with pleasure that Madame Jubault has presented a little daughter to her husband. M. Jubault has also been presented with a handsome gilt medal by the Touring Club for his services on the former occasion. We congratulate M. Jubault.

Next year it is proposed to have a Grand Motor-Car Concours from Paris to Vienna. It has also been suggested to have one from Paris to London, but the Channel passage has constituted a difficulty. The latest proposal emanates from M. le Comte de Dion, and it is a Motor-Car Competition from Paris to Berlin and St. Petersburg.

In spite of the patriotic and purely unselfish desire of the French agricultural "interest" to impose a tax upon motor-cars, but three out of 86 of the general councils have so far pronounced in favour of the proposal. Of course, the plea for a tax is that stale one which we hear so much of on this side—the necessity of maintaining the breed of "'osses."

With the steady increase of automobilism in France a new kind of mischief has arisen. If a motor is left at a hotel unattended it is becoming a favourite pastime with the street prowlers to set the mechanism in motion and see what happens. It would be just as well to provide a locking or braking apparatus so as to avoid any risk of this playful attention.

This is what a London correspondent of *La France Automobile* says of England:—"England is a country of absolute liberty. There are neither Customs dues, nor soldiers, nor policemen. The faults are the rates, which a policeman is always on hand to receive. Those who do not pay work a certain number of days on the streets, and so on. Happy England!"

It is said that the firm of Panhard and Levassor has been converted into a limited liability Company with a capital of 5,000,000 francs. The name of the new Company will be Société des Anciens Établissements Panhard et Levassor, the directors being M. René Panhard, M. Hippolyte Panhard, M. G. A. Clément, M. Descubes, M. René de Knyff, M. G. Pierron, M. Garnier, and M. Daimler.

The authorities at Vichy are emulating our own bumbles; they have issued an order to the effect that in the town the speed of motor-cars shall not exceed 4·8 miles per hour. Each motor-car must have an efficient sound apparatus, and must have a name plate and efficient brake. Motor-cars must not cause an obstruction, and must stop on the approach of a restive horse. Really it would seem that the excellent Maire of Vichy had been taking lessons from an English provincial magistrate.

A new type of motor-carriage has been recently completed by Messrs. Panhard and Levassor, of Paris, in the shape of a two-seated vehicle, fitted with a single-cylinder motor. The same firm has also constructed a small petroleum motor-vehicle to run on rails for the Northern Railway Company of France. The vehicle, which is to be used in connection with the postal service, measures only 8 feet by 5 feet, although intended to accommodate four persons, and is driven by a two-cylinder motor.

Two French gentlemen, M. le Comte de Beaumont and M. le Comte de Mussac, have just accomplished a remarkable journey of 2,480 miles in a four-seated Panhard carriage of 4¾ H.P. Leaving Paris on July 25th, they proceeded to Reims, Dinant, Spa, Liege, Brussels, and Ostend; returning to their home in La Vendée by coast roads of Normandy and Bretagne. The journey was without the slightest mishap, and was a most enjoyable one in every way, and the cost of the fuel was only a few francs. Had this journey been attempted with a coach and horses the expenses would have been very heavy.

In Great Britain the law relating to vehicles comprises something like 80 Acts of Parliament. France is trying to beat us. M. Lépine, Prefet de Police of the Department of the Seine, has signed an *ordonnance*, which, by the way, is a volume of 270 pages, defining what motor-cars may and may not do. Each motor-car must have an authorisation containing a minute account of the anatomy of the machine. Ownership must be specified. The responsibility for accidents is unmistakable and not to be evaded. Really this *ordonnance* reads something like our Explosives Act passed during the dynamite scare. The new law comes into force this month.

LAW REPORTS.

Motor-Car and Bicycle.

On August 18th, at the Fleetwood Police Court, two summonses issued against Henry Thomas, motor-car conductor, Blackpool, were heard; one for driving without a light, and the other for furiously driving a motor-car on the highway. On the first charge the driver was fined 5*s.* and costs. In the second case the driver was summoned for driving the car at a greater speed than 12 miles per hour, which was the limit permitted by the Local Government Board regulations. It was alleged that the car kept behind two bicyclists for over two miles, and the men had to ride as hard as ever they could to escape being run over. Finally they got to a place where there was a cross road, and they turned up this lane and thus got out of the way of the motor-car. To illustrate the rate at which the car was travelling, Mr. Blackhurst, who prosecuted, said that it travelled over a distance of half a mile in one minute and 55 seconds, which was equal to a rate of 16 miles per hour. Evidence for the prosecution was then given including the usual police evidence as to speed.

For the defence Mr. Bracewell, one of the occupants of the motor-car, said he had ridden bicycles ever since the days of the old "bone-shaker," and had also ridden a motor-bicycle, so that he was accustomed to calculate speed. In his opinion the motor-car never travelled, during the time stated, 16 miles per hour. Defendant was a careful driver, and the car never went more than 12 miles per hour. When the constable came up and said they had been going at 15 miles per hour, witness said it was nonsense and an impossibility. Other evidence having been given, the Bench retired, and said they were satisfied that a greater speed than 12 miles was driven, and defendant would be fined 10*s.* and costs.

The Locomotives Act.

On August 26th, at the Newcastle Police Court, the adjourned summons against Walter Morrison and Co. for a breach of the Locomotives Act, 1865, was heard. Mr. R. S. Holmes, who prosecuted, said the case against defendants was that having three wagons attached to a traction-engine they employed only three men to take charge, instead of four. The law was that if there were more than two wagons there must be an extra man to look after them in addition to the driver, stoker, and flagman. The defence, he believed, was that there was a fourth man. Unfortunately an accident occurred on the date of the offence (August 5th) in Barrack Road, by which a little boy was killed. At the inquest there was no suggestion that there was a fourth man in attendance until after the accident. Mr. Holmes then called witnesses, who swore that there were only three men in charge of the engine and wagons. For the defence it was submitted that when the engine and wagons left Elswick on the return to Newcastle there were four men. Mr. Hall, who defended, expressed regret, on behalf of defendants, that there should have been any accident. After hearing all the evidence, the Bench came to the conclusion that there had been a breach of the law, and expressed dissatisfaction with the evidence of some of defendants' witnesses. They imposed a fine of £10 and costs.

A sitting was held on August 24th at the Bankruptcy Court for the public examination of W. Marshall, mining and electrical engineer, of 16, Tokenhouse Yard. Although the liabilities were £12,945, the assets were estimated to produce a surplus of £43,000. In the course of his trading he found £6,000 or £7,000 in connection with patents which were eventually taken over by the London Electrical Omnibus Company (Limited), formed in May, 1896, with a capital of £250,000. As consideration for his interest in the patents, the debtor was to receive £20,000 in cash and £80,000 in shares; but he ultimately agreed to accept unsubscribed shares to the extent of £27,633 for returning £13,816 of the cash consideration. The debtor attributed his failure to inability to realise these shares in the London Electrical Omnibus Company (Limited), and to other causes. A proposal having been lodged for the payment of 20*s.* in the pound to the creditors, the meeting was adjourned to October 20th to enable the necessary steps to be taken.

A Drunken Motor Cabman.—The conduct of motor-cars and cabs has so far been marked by great skill and care on the part of the drivers, and up to a few days ago no charge of insobriety has ever been made against anyone in charge of a motor-car. This honourable record has at length been destroyed by one, George Smith, 25, of 192, Portnall Road, Harrow Road, who was charged at Marlborough Street, London, on the 10th inst., with being drunk when in charge of a motor-cab, of which he was the licensed driver. P.C. Russell, 247 C, stated that he saw prisoner in Bond Street in charge of a four-wheel electric cab. Suddenly the vehicle swerved from one side of the road to the other, and ran across the footway, into No. 165, New Bond Street, breaking the water-pipe and the beading of the window. Thinking that prisoner was unable to manage the vehicle, witness asked him to get down from the box, and, finding that he was drunk, took him to Vine Street Police Station. He then denied being drunk, and the divisional surgeon was sent for, who certified that he was. The prisoner, in his defence, admitted having had two or three glasses of beer. He was very sorry, and said it was the first time he had been charged with being drunk in charge of a cab. Mr. De Rutzen, the magistrate, said: "You motor-car drivers ought to be very careful, for if anything happens to you the police, who have a happy knack of stopping a runaway horse, might find that stopping a motor is a very different thing. There will be a fine of 20*s.*" To Mr. George Smith, then, belongs the distinction of being the first driver to be convicted of being drunk on a motor-car.

Horse Statistics.—According to the Police returns, the number of horses employed in London amounts to 80,000; of which 20,000 are employed in the omnibus traffic, 10,000 on tramways, 15,000 in the cab trade, and 3,000 by brewers. The railway companies own 21,000; coal merchants, 2,500; municipal bodies, 1,300; tradesmen, 2,000. Messrs. Carter, Paterson, and Co. own no less than 6,000. It is estimated that 26,000 horses are killed annually in London. So frequently is the cry raised "'orse dahn!" that even the street boys are connoisseurs in the art of street slaughtering, and regard that operation with a charmingly *blasé* air. But let a motor-car incur some temporary disarrangement, and lo! and not only does the crowd shout, but a "free and enlightened Press" joins in the cacophonous chorus of silly delight.

New Motor-Car Wheel.—Mr. John Nutsford, of Carlisle, is credited with having invented a new form of wheel, which is intended to supersede the present pneumatic-tyred wheel in general use. It is stated that he has arranged terms for the sale of the patent for the magnificent sum of £100,000. The purchaser is Mr. John Price, C.E., of Workington, who is acting on behalf of a number of gentlemen in that town who are about to acquire the Cumbrian Cycle Works there, and to float a company under the name of the Cumbrian Cycle and Motor Company (Limited), with a capital of £250,000, it being intended to lay down plant sufficient to turn out from 200 to 250 bicycles, and from 1,000 to 1,500 of the Nutsford wheels per week. The new wheel has two rims, an inner and an outer one—an ordinary solid or cushion tyre being fixed on the latter—and the two are connected with each other by means of two rows of coil springs, the ends of which pass through each rim and are secured by nuts. The arrangement of the springs and the manner in which they are fastened is an important feature of the invention.

COMPRESSED-AIR LOCOMOTIVES.

In our recent issues we have mentioned that on the New York elevated railways compressed air was about to be tried as the motive power. Previous experiments had been made in this direction, but with little success, owing to the low pressure of air carried in the reservoir. By adopting a series of tubes made a Scotch engineer. It has been in successful operation for nearly a year in connection with tramcar propulsion, and it was this success and the many advantages of the system that led the directors of the Elevated Railroad Company to give it a trial. Referring to the accompanying engravings, Fig. 1 is a general view of the locomotive from which it will be seen that externally the air locomotive looks somewhat like an ordinary steam locomotive but without the funnel of the latter. Figs. 2 and 3 are transverse sections showing the nesting of the tubes and

Fig. 1.—New York Elevated Railway Compressed-Air Locomotive.

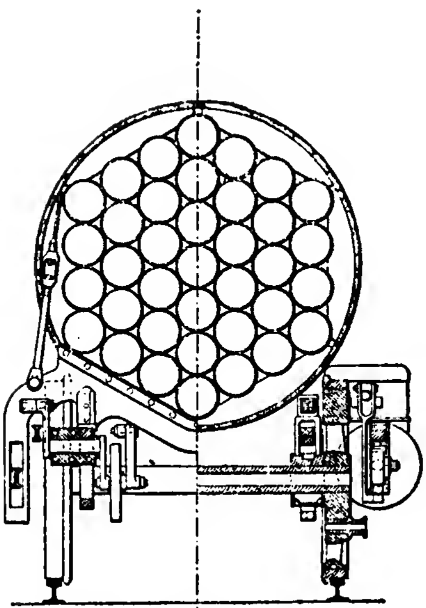

Fig. 2.

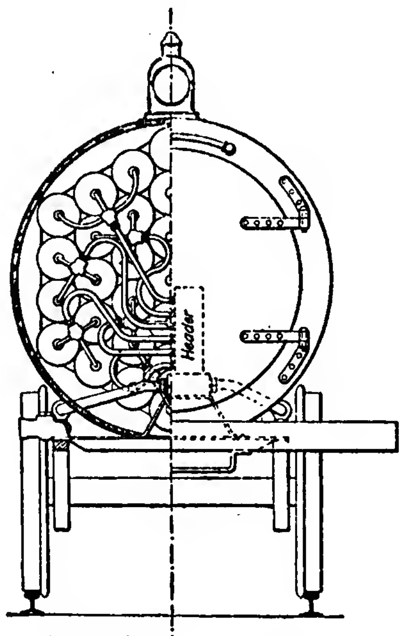

Fig. 3.

on the Mannesmann process as the reservoir, such a high pressure as 2,500 lbs. on the square inch can be safely carried, and sufficient energy can be stored to enable the locomotive to perform its duty with the same certainty as steam. The present system is the invention or design of Mr. Robert Hardie, their connections. These tubes are 27 in number, 15 feet 6 inches long, and 9 inches in diameter. They are made of steel and are homogeneous throughout. Indeed, it is the Mannesmann process that enables such high pressures as are now common to be used at all. Since on expanding air there is a fall of temperature, it is necessary to heat the air as it passes to the cylinder; this is effected by means of a hot-water tank holding 50 gallons of water, which is heated by a stove. The air from each reservoir is led by a small pipe to a vertical collecting chamber, from whence it is led by pipes to the cylinders. As the air is at very high pressure, reducing valves are interposed in the passage, and the air reaches the cylinders at about 150 lbs. per square inch. The driving mechanism is like that of an ordinary locomotive, and calls for no special remark, except that a Meyer cut-off gear is fitted. The dimensions of the engine are as follows:—

Cylinders	13 ins. by 20 ins.
Driving wheels	3 ft. 6 ins.
Driving wheel base	6 ft.
Total wheel base	13 ft. 6 ins.
Weight on driving wheel	16 tons.
Weight, total, in working order	22 tons.
Ports, inlet and outlet....	1 in. by 12 ins.
Valves, travel	3 ins.
Valves, lead	$\frac{1}{8}$ in.
Valves, lap	$\frac{1}{16}$ in.

The engine is intended for service on the Sixth Avenue line from Rector Street to Fifty-eighth Street, a distance of 4½ miles, with 14 stops, hauling a train of 130 tons. On trial the engine has made easily 45 miles per hour. The pressure of air carried is 2,500 lbs., and this can fall to 450 lbs. before it is necessary to re-charge. At the charging station there is a quadruple air compressor having cylinders $21\frac{1}{4}'' + 9'' + 7'' + 3''$ by 36" stroke. This will compress 500 cubic feet of air per minute to 2,600 lbs. The air is stored in a battery of Mannesmann tubes having a total capacity of 820 cubic feet, the time required to charge the locomotive being but 1½ minutes. The air compression engine is driven by a Corliss engine of 230 H.P. These trials are being watched with great interest on both sides of the Atlantic, and we trust they will be successful.

An Electric Omnibus.—There is now in operation at Greenwich, U.S.A., an electric omnibus which runs on the main road, without rails, but is supplied with current from an overhead wire, and while such a system is not of very general application it is thought, says *The Engineer*, that there are many cases in which such a service can be successfully installed to replace horse omnibuses on country roads, as between a small town and a railway station a few miles distant. The carriage was formerly driven by storage batteries. It is mounted on four wheels, having pneumatic tyres, and the forward axle is driven by the motor, which is connected with the brake, so that as either one is put in operation the other is thrown out. The current is supplied to two overhead trolley wires—one outgoing and one return wire—8 inches apart, which are suspended from a third wire by triangular metal frames. The "trolley" device consists of a set of rollers running on one or other of the two main wires, and so attached as not to fall off or run away when the carriage is descending a hill. This is attached to a double wire, which passes over the top of a pole at the back of the carriage, and the end of which is wound on a spring drum of the carriage. If the carriage crosses from side to side of the road the wire is paid out, the spring drum keeping it taut. The poles for the overhead wires are 150 feet apart, and they are partly on one side and partly on the other side of the road, but there is no trouble with the contact device where the wires cross the road. The present distance is a quarter of a mile, but is now to be extended from the town to the railway station, 1½ miles, the town having refused to allow the construction of an electric tramway on this road. The run of a quarter of a mile is made in 45 seconds, but the object of the experiment has been to obtain convenience rather than speed. The carriage can run in either direction, turn round, and move across the road to avoid other carriages. Two carriages can be run, having trolleys on the two wires. The carriage is practically noiseless, and is practically equal to a two-horse omnibus.

AUTOMOTORS IN A.D. 2000.

THE great American socialist author, Edward Bellamy (author of "Looking Backward," &c.), in his latest work, "Equality," takes a very enthusiastic view of the future development of automotors. He predicts that in the twenty-first century the horse will be as extinct as the dodo, his place having been taken by the electric motor. His disappearance is also responsible for an improvement in the public roads.

This new work is a sequel to "Looking Backward." In "Looking Backward," Mr. Bellamy described the world as he thinks it will be in the year 2000, and in his new book, "Equality," he enters into details and explains how the revolution was brought about which inaugurated the millennium before described. The story of "Looking Backward" briefly summarised is as follows:—

In the year 1887, Julian West, a rich young Bostonian, being a sufferer from insomnia, caused a chamber to be built of stone beneath the foundation of his house for use as a sleeping room. When even the silence of seclusion of this retreat failed, he called in a professional mesmeriser to put him into a hypnotic sleep, from which his manservant, Sawyer, knew how to arouse him at a fixed time. One night, when under the hypnotic influence, West's house was burnt down and he was supposed to have perished in the ruins. He was, however, safe and sound in his secret chamber, and 113 years later, September, A.D. 2000, Dr. Leete, a Boston physician, in conducting excavations in his garden, came upon this vault and discovered West still in his sleep. Dr. Leete resuscitates him, and after a short time West returns to the full vigour of youth which his appearance still indicated. His experiences and observations, naturally under the guidance of the doctor, are set forth in "Equality"; and in the course of the book the hero discovers that:—

"Thanks to the passing of the horse, it was possible to reduce the breadth of the roadways by half or third, to construct them of smooth concrete from grass to grass, leaving no soil to be disturbed by wind or water, and such ways once built, last like Roman roads, and can never be overgrown by vegetation."

Electricity has also replaced the horse in all agricultural operations. Julian West, taking an airship, sails over the Continent for the purpose of seeing the changes that had been brought about in the new area, which he describes as follows:—

"I saw a large field from which the crops had been cut. Over its surface was moving a row of great machines, behind which the earth surged up in brown and rigid billows. On each machine stood or sat in easy attitude a young man or woman with quite the air of persons on a pleasure excursion

"Evidently," I said, "these are ploughs; but what drives them?"

"They are electric ploughs," replied the doctor. "Do you see that snake-like cord trailing away over the broken ground behind each machine? That is the cable by which the force is supplied. Observe these posts at regular intervals about the field. It is only necessary to attach one of those cables to a post to have a power which, connected with any sort of agricultural machine, furnishes energy graduated from a man's strength to that of a hundred horses; and requiring for its guidance no other force than the fingers of a child can supply."

This revolution is not only in agriculture, it is the same in all other kinds of work:—

"Almost no heavy work is done directly now, machines do all, and we need only to guide them, and the lighter the hand that guides, the better the work is done."

"With one of our shovels," says the guide and friend, "an intelligent boy can excavate a trench or dig a mile of potatoes quicker than a gang of men in your day, and with no more effort than he would use for wheeling a barrow."

Not only is everything done by machines, but Mr. Bellamy holds out a prospect of our being able to make machines without hands, by the direct exercise of our will power. Electricity as an omnipotent instrument delivers the race from any necessity of manual labour.

A truly pleasant picture.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to The Editor of "The Automotor and Horseless Vehicle Journal," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. King and Co., Limited, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. King and Co., Limited, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

SPECIAL NOTICE.

The Automotor and Horseless Vehicle Journal *can be obtained from all* Messrs. W. H. Smith and Son's *bookstalls, and the following Agents:—*

London: Pottle and Sons, 14 and 15, Royal Exchange, E.C.
Wholesale: Brett and Co., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. McCann, 37, Union Street.
Manchester: John Heywood, Deansgate.
Newcastle-on-Tyne: C. C. Ross, 35, Side.
Paris: Homère Moreau, 97, Rue Nollet.
Victoria (Australia): Phillips, Ormonde, and Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

SEPTEMBER 15th, 1897.

ANSWERS TO CORRESPONDENTS.

A. H. H. (Eccleshill).—The address of the London Electrical Cab Company is Juxon Street, London, S.E.

J. W. (Northgate, Halifax).—We cannot send you a copy of the pleadings, as we have no authority to do so, but your best plan would be to apply to the solicitor who has the whole of the cases in hand.

F. Beech (Ilkley).—(*a*) The number of the patent is 11,307 (1896), which can be obtained from the Patent Office, Chancery Lane, for 8*d*. You will notice that a diagram and particulars of same appear in this issue. (*b*) We are sorry we have no No. 1's, which is out of print. We are sadly in want of them ourselves.

Steel Tubes and Frames (Westminster.)—Several first-class firms are willing to manufacture to design. Apply to such Companies as the New Brotherton Tube Company (Limited), Wolverhampton; Standard Weldless Tube Company, Victoria Street, Westminster; I. Oldbury, Reliance Works, Wednesbury; Climax Weldless Tubes (Limited), Catherine Street, Lichfield Road, Birmingham, &c.

W. Bobbett (Teignmouth).—It is impossible for us to enter into private correspondence with inventors relative to designs, &c. We have received your models, and, while they are ingenious, the principle adopted by you of making one car-frame serve for other kinds of bodies is not new. At the recent Agricultural Hall Exhibition there was a motor-car shown which possessed this featnre. We would suggest that you get out a complete set of working drawiugs and submit them to some firm of engineers or carriage-builders. If the design commended itself you would have uo difficulty in getting a car made.

A. Jackson (Birmingham).—No, do not wash your rubber tyres with any kind of mineral oil. Petroleum is a powerful solvent.

R. L. (Wednesbury).—In ordinary work a bicyclist develops about $\frac{1}{10}$ H.P.

J. Johnston (Liverpool).—Your valves probably want grinding in. You had better let this be done by an engineering firm.

P. Alston (Belfast).—The cause of the steam-motor not starting is that owing to the position of the cranks the admission valve on the horse-power engine is closed by the slide. Reverse and get the cranks into a better position, then put the links for the go-ahead position.

G. Jennings (Manchester).--The best pumps we know of for pumping petroleum are the Worthington.

OURSELVES.

There are times in the histories of newspapers as of individuals when a little self-congratulation may be rightly indulged in. Such an occasion now presents itself to us; with this issue the Automotor completes its first year's existence. A year ago the automotor industry hardly existed, and the idea that it required (as what industry does not?) an organ in the Press to represent it seemed to many people rather premature. We, however, recognised that automobilism had at length come to stay and is destiued to become a powerful factor in solving the economic problem of cheap internal transport, and an independent organ which should do something towards educating the people ou the subject seemed to us eminently desirable. We therefore projected this journal upon the public and are glad to say that not only have our efforts in this direction been attended with considerable success, but also that the results to ourselves have beeu no less so. The importance of automobilism is very generally recognised, and this is shown by the fact that many of our coutemporaries devote more or less attention to it; but obviously the industry will be best served by a journal exclusively devoted to it, and this is the function of the Automotor. We have to record a steadily increasing circulation—the best proof that our efforts are appreciated. Our success is largely due to the fact that we are strictly catholic in our views; we have no financial or other interest in any motor, but are glad to publish the good points of each and to give friendly criticism of all.

A year ago, when motor companies were being floated with excessive capitals and exaggerated prospects, we warned our readers that the industry did not then warrant exploitat on on a large scale. Our views have been amply justified by events. Since the automotor first appeared, very substantial and satisfactory progress has been made in the industry. Crude types have been perfected or abandoned, the general design and construction have been improved, and the motor-car of to-day is a reasonably reliable vehicle. All these various steps in the process of the evolution of the motor-car have been duly recorded in our pages. Much, however, remains to be accomplished before the motor-car attains the perfection of the locomotive; this will be greatly facilitated by the dissemination of ideas through the pages of an independent journal, and this is the task we have set ourselves in the Automotor. Designers and constructors will find in the Automotor particulars of the latest advances iu automobilism, and we spare no pains to make our information accurate and useful. As occasions offer, we publish detailed technical descriptions and working drawings of successful motors, and we find that they are much appreciated. Automobilism, as its name indicates, is not necessarily confined to traction ou roads. A Whitehead torpedo, a canal tug, or Thames steamboat, and a flying machine are also automotors, and these will be discussed in our pages. So much for the industry.

In other directions we shall be uo less active; the motor-car has many insiduous enemies, and not a few people would do much to hinder its progress. As our readers are aware, we cast a severe and minatory eye upon those who, entertaining a misguided prejudice in favour of the horse, allow the scales of justice to incline against the users of motor-cars. There are also those who, under the plea of the safety of the public, seek to restrict the sale of petroleum and its products, thereby striking a blow at the manufacture of light oil motors. *We've got them on the list.* It will thus be seen that there is plenty of work for us and a wide field for our operations. We have every assurance that, so far, our efforts are appreciated by our readers. We shall eudeavour to deserve that appreciation.

SITTING ON THE FENCE.

It is frequently said that automobilism is far more advanced in France than in England, as indeed it is. The reason is that those who should lead in this matter in England have been sitting ou the fence. We hear wails in the Press, because very large orders for electric tramway plant go to America. The reason is that our tramway directors sit upon the fence; they wait and see, and won't encourage anything in the nature of experiment. Oh, oh! they are prudent business men. And so in London we have about the worst tramway system to be seen anywhere, and we still cling to the "gee-gee." In another column we describe a compressed-air locomotive, the invention of a Scotch engineer, who could not get his proposals considered on this side. Our railway directors, as usual, are sitting on the fence. In London we have two railways—the Metropolitan and District—for which air-compressed locomotives are eminently desirable. Although for many years past the bad ventilation on these lines has been a continual reproach, and has even called for Parliamentary notice, yet nothing effective has been done—the directors are sitting on the fence.

On the River Thames we have the worst steamboat service—if such it can be called—of any capital city in the world. Similarly our Fire Brigade engines are simple, low pressure, obsolete, horse-drawn vehicles, that would hardly be thought good enough for a bush township in Australia. And what is the London County Council doing in these matters? Why, sitting on the fence. In other directions we see the same extraordinary apathy, inertia, and disinclination to shift out of a rut. We complain of foreign competition, low prices, and strikes; yet what are the leaders of public opinion doing to lessen these economic evils? Why, nothing; they are sitting on the fence all the time.

SOME ESTIMATES OF THE HORSE.

There was once a certain schoolboy who was required to write an essay upon the horse; he commenced:—"The horse is a noble animal, very useful to man; he has a shiny coat, and eats oats." Although somewhat lacking in literary style, these statements are, in the main, correct, if insufficient. We are not disposed here to amplify them; on the contrary we should rather like to dispute with this juvenile authority the question of nobility, although we know we should be hopelessly beaten, because, gazing one afternoon with mingled awe and admiration at the mounted cavalry men in Whitehall, we heard several exclamations from a crowd of females to this effect:—"Oh, don't they look lovely! Ain't they noble!" Whether *they* meant the horses or the riders, or both, we could not ascertain with definite accuracy, but there can be no mistake that to many minds, especially those of females, the horse *is* a noble animal. In view of certain recent utterances by eminent men, it has occurred to us that the schoolboy or student of the future may in passing an examination be required to answer some such questions as these:—What mechanical principles are involved in the anatomy of the horse? Regarded as a machine, what is its efficiency? What is the average useful effort of a London cab horse? How would you "indicate" a horse? Compare a horse with a motor-car and state the cost of energy in each? Also estimate their commercial efficiencies? In order to answer these questions our student would consult the authorities on horses and motor-cars, and he would very properly look up Sir David Salomons's paper on motor traffic. In that excellent monograph he would read:—"Finally, the best existing motor the world has yet seen for its power, method of fueling, suspension springs, and travelling long distances before recharging, is . . . . the horse." This is somewhat like the essay referred to; it is a series of direct statements, well expressed, and, to many people, quite conclusive.

Our student might, however, have consulted another high authority, Mr. W. H. Preece, F.R.S., who inaugurated the electrical cab service in London recently, and who in the course of a humorous and interesting speech said:—"Now, the horse was a very imperfect creature in several respects. He was constructed on principles which were horrible in their operation. He moved in unstable equilibrium, and sometimes got a bad fall in consequence. Then he was very weak in his head, for if he got frightened or disturbed, God alone knew what he would do. They had seen only the other day how a horse ran into the post-office at Ludgate, the very last place where he would hope to find peace and quiet, and there did a good deal of mischief before he could be quieted. Then the horse must be well fed. He was subject to disease as we were, and he was short-lived. The driver and his horse might easily come to grief together. Still, they must all love the horse and care for him in the best way they could; but it might become necessary to see whether they could not find another way of serving his master better."

Here, then, we have from two high authorities in engineering science two absolutely opposite statements; both cannot be right, and it would be instructive to learn why Sir David Salomons regards the horse as such a perfect motor and why Mr. Preece holds that it is such an imperfect one. We should not think of deciding the question in the face of such diverse views, but we may point out that much depends upon the point of view adopted. Like our schoolboy, Sir David evidently regards the "nobility" and the "glossy coat" of the horse as factors in estimating its value as a motor, and rightly so, because the æsthetic sense has to be satisfied. For the combination of strength and grace the horse is unquestionably a perfect embodiment. Mr. Preece seems to approach the animal in a severely materialistic and utilitarian spirit. He simply asks himself how to move this cab in the cheapest and safest manner, and he therefore condemns the horse as inefficient, and no one will, we think, venture to contest his verdict. In recounting the apparent discrepancies in the views expressed by these distinguished men, we must also consider the environment. In the country the horse forms a pleasing feature which harmonises with surrounding objects. He is not then objectionable, but, on the contrary, as our schoolboy says, "very useful to man." In the towns, for which use Mr. Preece was considering him, he is an unmitigated nuisance, to be condemned alike on sanitary, hygienic, and humane grounds.

THE IRISH MOTOR COMPANY.

Considering the standing of the directors of this abortive Company, it surely was reasonable to suppose that they had satisfied themselves that there was a business to be done before going to allotment, and that their property in patents, &c., was of some value. On these elementary points the directors evidently failed to obtain reliable information. It is not often we see men of position and wealth displaying such a want of business knowledge, and we are afraid that the reputation of the directors will hardly be enhanced by this stupid fiasco. They also seem to have acted with precipitancy in exploiting machines of but very doubtful commercial value or utility. Considering who these directors are we quite fail to understand how they contrived to place themselves in such a ridiculous position. The Board included Alderman Meade, who has been Lord Mayor of Dublin twice, and who is a Privy Councillor and LL.D. of Trinity College, Dublin, a director of several companies, and one of the largest building contractors in Ireland; the Right Hon. S. A. Dickson, Q.C., late M.P., well known as an Ulster Liberal and as an authority on land matters, and who has been a member of Royal Commissions, &c.; Mr. J. Malcolm Inglis, J.P., Scotsman, and coal importer, well known on Unionist platforms in Scotland; Sir Howard Grubb, F.R.S., of telescope fame. Individually these men are no doubt eminent in their various walks of life, and no one would think of questioning their ability to mind their own business. Collectively they displayed the innocence and business capacity of babes and sucklings and—and this is their only redeeming feature—with the transparent honesty of such. The directors of the Irish Motor Company have acted as men of good moral but very bad business principles. We cannot but regret that the concern was ever started, as it is such things which retard the automotor industry. There is one more point. The directorate of this Company illustrates again the folly of shareholders putting money into a manufacturing concern, the technical details of which manufacture they know nothing and the direction of which is in the hands of men who know less. What but disaster can possibly be expected? What practical knowledge of traction did these directors possess? The answer is, None, because had they such knowledge they would probably never have attempted to acquire such "valuable patents."

AN ABSURD CANARD.

A FEW days ago as a motor-car belonging to Messrs. Arnold Goodwin and Son, of Southwark, S.E., was proceeding across Ludgate Circus it collided with a van and the shock damaged the naphtha reservoir and caused a leak. The naphtha ran out and the car had to bring up in an adjacent bye street. Repairs were effected inside of half an hour, and the motor-car proceeded on a 20-mile journey. To the surprise of everyone with the slightest knowledge of motor-cars, the Press almost with one accord published a series of the most untruthful and misleading accounts of the affair under full headlines and large capitals that could be imagined. Occurring where it did right in the heart of the journalistic world, there were no doubt a good many scribes in the crowd who saw in the accident a chance of making "copy," and very fine and lovely was the "copy" that appeared the next morning about this trivial matter. The *Daily Mail* especially distinguished itself. Many other papers with some reputation for sobriety, such as the *Whitehall Review*, ran the *Daily Mail* closely. It seemed that for some occult reason or other there was a unanimous desire on the part of the Press to magnify a temporary defect into an "alarming explosion of a motor-car." We can only express our astonishment that apparently respectable organs of public opinion could lend themselves to publish such utter drivel. At the recent meeting of the Institute of Journalists at Cardiff, we heard a lot about the "dignity of the profession," the "responsibility of the Press," and so forth, and yet we see these "dignified" and "responsible" editors publishing with a light heart and without inquiry a tissue of falsehoods; and journalists wonder why the public does not think more of them? The actual facts of the "explosion" as communicated by Messrs. Arnold Goodwin and Son are these:—The car is propelled by a Benz motor, and is in daily use in the City for commercial purposes. The cause of the trouble was a weak spring in the exhaust valve, this not closing sufficiently caused the carburettor to leak; there was no explosion. We have been asked, Why does the Press publish such absurd and mendacious statements as this one? The reason is, we think, this: We must recollect that there is a very close connection between the daily Press and the turf or horsey interest. All or nearly all of the daily papers depend largely for their circulation upon the horse racing and betting intelligence. The horse, like the soldier, is a fetish with the great British public, and therefore the motor-car is naturally disliked, and the Press reflects this opinion and exaggerates in an absurd manner every trifling accident that occurs. The more intelligent section of the public recognises that all mechanism is liable to get out of order, but inasmuch as the motor-car offers such undeniable advantages over the horse these minor accidents are not seriously regarded by sensible people. We by no means quarrel with those papers who publish such canards as the one we have referred to, only we would ask those editors and others concerned: Does it enhance your professional reputation? Does it tend to increase the public respect for your paper to publish wilfully what after all is an utter falsehood?

THE PRESS ON THE ELECTRIC CAB.

IN a leaderette, the *Daily News* of August 20th, says:—The motor-cab appeared in the London streets yesterday, and with some pomp and ceremony. It is not exactly a thing to take the winds of March with beauty, but neither is the "growler," to which variety it belongs. It is driven by electricity, which means that it makes neither noise nor smell, and it has the supreme virtue in cabs, that it gets along. One stray specimen from the well-stocked depôt of the Company in Lambeth was seen mounting the incline of Norfolk Street in a most spirited manner, with two fares inside. They were apparently in collusion with the driver; but the attempt of all three to look as though they had been doing that sort of thing all their lives was a distinct failure. The cabman manifestly could not meet the eye of his fellow-driver of the old dispensation. He carried no whip, and somehow looked like a person who had forgotten some essential article of clothing. In this respect his appearance was almost indelicate. The other drivers were moody or thunderstruck—at any rate, they said no word. They may have felt that "blackleg" was below the necessities of the situation. The cab seems to turn about and wheel about with the facility of the Jim Crow of negro melody. It looks like a cross between a brougham and a four-wheeler, and it has a sort of bustle, where bustles should be, which may be supposed to contain the apparatus. This will afford the small boys a more comfortable seat than the ordinary springs, and will probably disarm the opposition of their powerful corporation to the change.

A representative of the *St. James's Gazette* interviewed Mr. W. Bersey, the manager of the Electrical Cab Company, and in answer to questions the latter said:—"The prospects of the Company were excellent. We haven't half enough cabs. Our full complement at present is 15; but of these 10 are hired privately every day. As a matter of fact, I could send out the whole 15 under like conditions—namely, 25*s.* a day; but we think it desirable to have as many on the streets as possible. The new vehicle is already very popular. The other day one of our men returned from his day's plying for hire with gross receipts amounting to £2.

"I think we have reason to be satisfied with a driver who brings us in a profit of 30*s.* a day from one cab. Others have earned considerably over a £1. One of our men came back with 12*s.* as the result of three hours' work, while another earned £1 2*s.* in six hours.

"We are getting a regular supply of three new vehicles a week, and we could wish that they came in more rapidly. We could easily find work for at least 100 cabs, even if they were confined to private hiring."

In answer to the question, "How will the introduction of the motor-cab affect the ordinary cabman? Is there likely to be a rush for the new cabs, and is it true, as was stated at a meeting of cabmen the other day, that if such a rush occurs you will immediately raise the price of hire to the cabby?" Mr. Bersey replied, "No; to take the last question first, we have no such intention. We find no difficulty in obtaining drivers qualified to manage the electrical cab. An intelligent man can easily make himself proficient in two days, and we immediately send him round to Scotland Yard, where the authorities unhesitatingly grant him a licence if he proves himself to be a capable driver. As for the ordinary horse-hansom, I should be sorry to see it disappear. There is room for both kinds of vehicles in a great city like London."

NOTES OF THE MONTH.

THE Stock Exchange "tape" quoted motor-cars recently as "'orseless carriages."

MESSRS. AVELING AND PORTER (Limited), of Rochester, have secured the contract for supplying road rollers for the Norfolk County Council.

A MERCHANT at Washington, U.S.A., applied for permission to use a horseless delivery wagon, but the permit was refused by the District Commissioners on the ground that horseless vehicles frighten horses, and are likely to cause runaways and accidents!

THE Glasgow Sanitary and Open Spaces Committee have serious thoughts of using motor-vehicles in connection with their sanitary system. A deputation was the other day appointed to report upon the subject after they have obtained practical information upon the subject at Coventry and elsewhere.

THE Board of Admiralty have appointed Mr. Stanley Dunkerley, M.Sc., of the Department of Applied Mechanics, Cambridge, to be Professor of Applied Mechanics at the Royal Naval College, Greenwich, in succession to Professor J. H. Cotterill, M.A., F.R.S., who is about to retire from that post after over 24 years' service.

AT the recent half-yearly meeting of the London General Omnibus Company, Mr. Burns, one of the critics of the methods of the directors and who evidently believes in motor omnibuses, drew attention to the danger of increasing the stock of extra buses with a prospect of having in the near future to purchase electrical and other motor buses.

THEY are very fond of motor-cars in Ireland. Last month in connection with a bazaar held at the Bray Town Hall, the principal prize was a motor-carriage, the drawing being presided over by Sir Rowland F. N. Fanning, J.P. The prize was won by Miss Boland, 29, Upper Leeson Street, Dublin, who was the lucky owner of ticket No. 3,928.

THE Burnley Corporation have purchased a motor steam mowing machine, and it has been put to work in Queen's Park, where crowds of people collected to see it. It has cost nearly £100, but there is no doubt as to its utility. The machine saves both horse and manual labour, only one man being required to attend to it. It not only cuts the grass, but rolls as well. Its weight is 16 cwt.

WE understand that the Motor Touring Company of Llandudno is so far satisfied with the result of its experiment that next season many more motor-cars will be employed, and the whole thing done on a more extensive scale. That the public appreciate the motor-cars is indisputable. Nervous and timid people who would not sit behind a pair of high-spirited horses for all they were worth, have no hesitation in going on board a motor-car.

ACCORDING to the *Financial News* a great tube combination is being attempted in Birmingham, the idea being to amalgamate all the manufacturing firms in England and America. The price of tubing will be put up at least 100 per cent., which means that the present discounts will be reduced to equal this increase in price. At the same time an association is to be formed among the tube-drawers, who are asked to refuse to work for any firm or company which is not affiliated to the master tube association. The men are being told that this will be to their advantage as their wages will be maintained if their employers are able to sustain the prices. So far, however, the proposed amalgamation has not made much headway.

THE experiment with motors as dust collectors being made by the Chiswick Urban District Council, is exciting much interest among other sanitary bodies. So far it has proved successful. Mr. Ramsden, the Surveyor to the District Council, reports that a week's experience with one of the cars shows that they are very easily controlled, and far more economical than horse labour. The steam wagon does the work of three ordinary carts, and Mr. Ramsden estimates that the Council will save between £500 and £600 a year by the adoption of the new system. As a proof of the ease with which these motors are managed, he cites the fact that the driver of the steam-roller learned to control a motor in one or two days, and that the machine easily negotiated the steep incline of Kew Bridge with a load of two tons. The motor has a Thornycroft boiler working at 150 lbs. per square inch, and a horizontal engine of about 9 H.P. It is also fitted with a condenser.

THE ideal accumulator is hardly yet an accomplished fact if we are to believe the statements put forward by a Mr. A. W. Turner, of Birmingham, who writes as follows in regard to the Electrical Cab Company's accumulators, which weigh about 14 cwt. :—"Providing an accumulator can be produced to weigh 4 cwt. instead of 14 cwt., and yet supply the same amount of electric power, all of your readers must readily perceive that much better results can be obtained—a lighter vehicle to carry the accumulator, &c. Two Birmingham men have invented and secured, under patent protection, such an improved system of electric accumulator: one man is a practical machine pattern-maker and millwright, and the other man is a practical, well-known metallurgist. Arrangements are being made to manufacture all kinds of motor vehicles for the streets of Birmingham and London, also to make hand-lamps as substitutes for the death-dealing paraffin lamp, the light weight of the new accumulator permitting of reading lamps being made that can be carried about easily from place to place, or in the pocket, also on cycles." We can only hope the above statements are correct, but for ourselves, before accepting them as accomplished facts, we are inclined to wait until we have practical proof of such results.

The Motor-Car in China.—There is probably no country in the world more suitable for motor-cars than Eastern China. The country, generally speaking, being a vast alluvial plain, travelling is not unpleasant so long as it is confined to the rivers and canals, but when it comes to making journeys of many days' duration in the native carts it is something awful. An enterprising firm that would introduce motor-cars would at once get all the business it wants. Unlike the railways, there would be no native prejudices to overcome, as the motor-car would not depreciate the *fengshui* of any locality. It could make a detour which the locomotive cannot. We are glad to note that the motor-car is likely to soon make its appearance in China. According to the latest issued diplomatic report a wealthy Chinaman of the capital has given an order for an automobile car to a French firm of manufacturers. It is not known that this example has yet been followed, but the vehicle supplied may, if proved to be constructed with the stoutness and solidity rendered requisite by the peculiar character of the metropolitan thoroughfares, be the means of creating a profitable demand.

LES POIDS LOURDS, OR THE HEAVY-WEIGHT MOTOR-CAR COMPETITION.

In our August number we described the principal features of this competition, and gave a description of the vehicles, but as the Automotor was published just as the trials had concluded we were unable to complete our account in time for that issue; moreover we were desirous of including in it the official report of the trials. Unfortunately this has not yet been issued by the Automobile Club. We now propose to give a short account of the performances of the competing vehicles as, without waiting for the official report, the data available is sufficient to enable certain general conclusions to he reached. It will not, we think, be denied that these trials have been of the utmost interest and importance, and when the official reports are issued they will furnish reliable data of the utmost value. From the description of the routes it may be assumed at once that the Versailles roads are really worse than would be experienced in ordinary country traffic, and if a vehicle successfully passed this onerous French trial it is safe to say that it is fit for any service. The "Scotte" Company had three entries; the first, officially known as No. 1, was a motor omnibus, having a seating capacity for 12 passengers and two attendants. Its weight, fully equipped, but without passengers, is 7,700 lbs. It is propelled by a pair of vertical engines of 16 H.P. It carried eight passengers and 1,496 lbs. of ballast and two sacks of coke. This vehicle ran all her trials in the most satisfactory manner, maintaining a fairly uniform speed, even on the gradients, of about 5½ to 6 miles per hour. No difficulty of any kind was experienced. It was stopped on the steep gradients and started again quite easily, and was at all times fully under control. Omnibuses of this type have been running between Colombes and Courbevoie, two suburbs of Paris, for some months past, and have, we understand, given great satisfaction. They are comfortable—at least they accord with the French idea of comfort, which in matters of travelling is hardly as advanced as our own. Certainly the Scotte omnibus is a step in advance of our own London bus. It is equally as ugly, but its great merit is that it (the Scotte) is not disfigured with advertisements and is not dependent upon horses. A good feature of the Scotte motor, as also of the De Dion, is the facility with which the steam pressure can be varied at will. While on the flat a pressure of about 6 kilogrammes per square centimetre, or 85 lbs. per square inch, suffices; this is quickly increased to twice this on reaching a gradient. This facility of obtaining extra power at will is the great secret, in our opinion, of the success of these motors. On Route C, 66·1 kilometres or 40·98 miles, the consumpt was 539 lbs. of coke and 400 gallons of water.

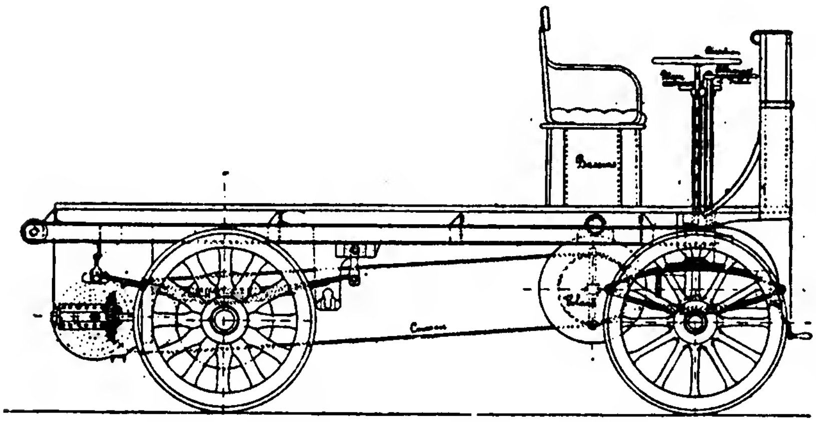

Fig. 1.—De Dietrich Motor-Lorry (Elevation).

No. 2 was a Scotte "tracteur à marchandises," or motor-wagon hauling a kind of goods truck. On this train were three persons and 9,240 lbs. of ballast. The routes were traversed without mishap; the speed being nearly three miles, the performance was considered remarkably good. No. 3 was a "train Scotte" or motor-omnibus hauling another omnibus, the total weight of the two being 11,000 lbs.* This train carried 23 passengers and 2,640 lbs. of ballast. The highest speed attained was 15 miles per hour, and on an incline of 14 per cent. the speed was 2·4 miles per hour. The starting and stopping trials were eminently satisfactory, the brake power ample, and the general performance very good. These Scotte trains have undoubtedly shown that heavy traction is quite a practical and commercial possibility even on the worst roads.

No. 4, a steam omnibus, designed and built by M. Weidknecht, well illustrates what we have often remarked, that a locomotive engineer is not necessarily an authority on horseless vehicles any more than an ordinary van-builder is. M. Weidknecht as a manufacturer of railway plant no doubt is an authority on railway matters, but we venture to doubt whether his ideas as carried out in this vehicle entitle him to be considered as a motor-car engineer. We gave the salient features of this vehicle in our last issue, and the impression that we gained by inspecting it was fully confirmed by its behaviour. On the flat this omnibus, which carried nine passengers and one ton of ballast, could hardly maintain a uniform speed, or perhaps it would be better to say that a uniform pressure of steam could not be maintained for any length of time and it fell on mounting the hills. Whether this was due to insufficient heating surface or excessive consumption of steam it is impossible to say off hand. The boiler appeared large enough, but it had to supply three cylinders. On the two easy routes the performance was on the whole satisfactory. But Route B, as will be seen, is calculated to try any horseless vehicle pretty severely, and the Weidknecht could not surmount the Côte de Picardie or the Côte de Pecq without stopping to breathe and quench an

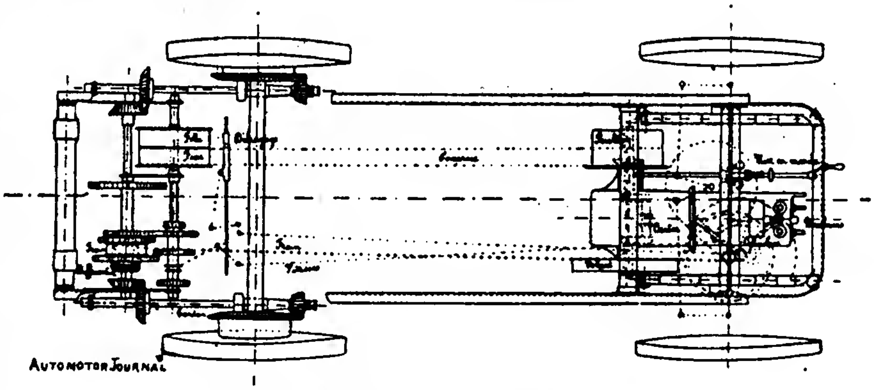

Fig. 2.—De Dietrich Motor-Lorry (Plan).

* In our last issue, p. 453, an error was made in the numbering of the Scotte vehicles. The Official No. 1 was placed in our table as No. 3 and *vice versâ*. The correct numbering is that now given.—Ed.

insatiable thirst. While adjourning to a convenient pump at Port Marly for this purpose the vehicle took charge and brought up against a house, both being hurt, the motor-car receiving severe injury to the under-frame, which rendered it necessary for her to abandon the competition. On a run of 28·35 miles, the consumpt was 732 lbs. of coke and 314 gallons of water.

No. 6 was the Le Blant brake, a vehicle of which we had formed a good opinion. A description of it will be found on pp. 454 and 455. Unfortunately, it broke down badly at the first attempt and also caught fire. It was withdrawn from this competition, but from its previous record we think M. Le Blant will be justified in modifying the design to the extent of making his vehicle a little more substantial, so as to give it a chance when tackling those awful Versailles routes.

No. 8 was a lorry by M. Dietrich; this vehicle is illustrated in Figs. 1, 2, and 3, which are respectively an elevation, plan, and rear view. The car is propelled by a petroleum motor placed underneath the fore part, driving by belting the rear wheels. It is steered by the fore wheels, all of which are of the same diameter, viz., 80 cm. = 31·49 inches. The motor is a two-cylinder horizontal Bollée, working on the usual Otto, or, to be more correct, Beau de Rochas, cycle. At 660 revs. it gives off 6½ H.P. There are two counter-shafts and the usual differential gearing. The method of transmitting the

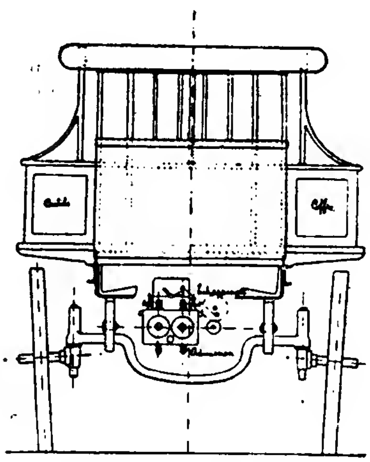

Fig. 3.—De Dietrich Motor-Lorry (Front View).

motion from the second counter-shaft to the rear wheels is decidedly novel. On the inner plane of each rear wheel is a bevelled-toothed wheel into which gears a bevelled pinion which is driven by bead wheels from the second counter-shaft. Four speeds are provided, ranging from 2½ to 9½ miles per hour. The weight carried is from 2,600 lbs. to 3,300 lbs., depending upon the road. The construction struck us as being very good, but we do not think the design would stand the test of prolonged work. The consumption of naphtha or gasoline is about 1½ pints per mile. The tanks will hold sufficient water and oil for a run of 50 to 60 miles. The dimensions of this lorry are 10·7 feet by 4·8 feet by 3 feet high, and its price is £240. From its performance this lorry seems to be a practical machine in spite of its peculiarities in design. It ran the trials well and gave satisfaction. It covered 40·98 miles in 10 hours, and the consumpt was 35·2 pints of oil.

The Panhard omnibus, No. 10, 12 H.P. Phœnix Motor (Improved Daimler), completed the trials very successfully. It carried 10 passengers and 660 lbs. of other weight. On the level it did all that could be desired, being fairly fast without any unpleasant smell or vibration. In climbing the hills the low-speed gearing has to be used, and the speed of course falls off very considerably—as low as three miles per hour, although the former speed was from eight to nine miles. While doing the distance (Route A), 25·6 miles, the consumpt was 39 pints of gasoline and 181 pints of water, and 26 pints of lubricating oil. We cannot but think that had the motor been more powerful it would have been an advantage in every way.

No. 13 was the De Dion et Bouton tractor, and No. 14 the De Dion et Bouton omnibus. These are illustrated in Figs. 4 and 5. In Figs. 6 and 7 we give two line drawings showing the arrangement of the motor mechanism in the omnibus. It will be seen that there is a pair of compound engines, CC, driving the shafting, H, on which are mounted the pinion D gearing, with G on the second-motion shaft which turns shaft E, on this latter is mounted the differential gear; for further description *see* pp. 456 (*ante*). Both vehicles performed admirably; they maintained a fairly uniform speed; even on the steepest gradients they were easily controlled, and starting and stopping on a hill was equally easy. In short, whether for passenger or goods traffic, it would be hard to improve upon these vehicles, although, as we remarked before, we cannot approve of giving such powerful motors wooden wheels, and we fancy that on prolonged service our criticism would be justified.

On a run of 25·6 miles the De Dion omnibus averaged 7·4 miles per hour, including stoppages, the consumpt being 220 lbs. of coke and 400 gallons of water. The De Dion Tractor consumed on a run of 24·6 miles 191 lbs. coke.

The char-à-banc of the Maison Parisienne, No. 15, of 9 H.P., Benz motor, carried 12 passengers and 790 lbs. of other weight. It was, however, unable to negotiate the steeper hills, and got stuck on the Côte de Picardie (*see* profile of gradient, Route B, p. 457), and had to unload before it could proceed. This occurred on the first day, and the judges ruled it out of the competition. It ran on succeeding days, but with less than half its former load.

These trials have been very closely watched by a good many others than those actually present at them, and they seem to have demonstrated two things: first, that heavy mechanical traction on even bad roads is perfectly feasible, and can be carried on on commercial lines; secondly, that steam is the better motive power. As regards the first, it may be said that the experience gained by the English pioneers in automobolism had already proved this proposition. That is no doubt correct, but the experiment is none the less valuable on that account, as it showed what economy in weight and space has been effected since Hancock's time by the employment of much higher steam pressure and motors having a high piston speed. Comparing, say, the "De Dion" and "Scotte" motor-cars with those of Gurney, Hancock, and other pioneers, the difference is not so very marked, and may be said to consist in the higher steam pressure now used. So long ago as 1802 Trevethick used 60 lbs. per square inch and got a speed of 10 miles an hour. In the French steam motor-vans the pressure is a little more than three times this, or 14 kilos. per square cm. = 198 lbs. per square. So long ago as 1830, a Select Committee of the House of Commons had reported that carriages conveying 14 persons and upwards, and not weighing more than three tons, can be propelled on common roads at a speed of 10 miles an hour, and we are not aware that the Versailles trials have improved very much upon this, excepting, of course, in the directions stated. Indeed, as Sir David Salomons pointed out at the Society of Arts, the steam coaches of Hancock and of many former designers could be run to-day with perfect success, and they would not be so very obsolete after all. It must not be supposed that we wish to discount in any way these heavy motor trials that have been held in France; at the same time we would remark that the results attained with the steam motors were, after all, merely corroborative. Thus the "Scotte" omnibus weighs light—7,700 lbs.; it can carry 14 persons = say, 1,500 lbs. and 660 lbs. goods at a speed of 6½ to 9½ miles on a consumpt of 13 lbs. of coke per mile, and *assuming* that the motor was giving off 16 B.H.P., the consumpt is 4 lbs. of coke per B.H.P. per hour—not a very remarkable performance, and one which has been equalled, if not excelled, by James, Gurney, and Hancock in their motors. Similarly, the De Dion motor-car does not call for extravagant commendation. Weighing about 4,400 lbs., it will carry 2,560 lbs. of goods or passengers, it will maintain a speed of 8½ miles per hour over a difficult road. To do this requires a 30 B.H.P. engine, the consumpt was 8 lbs. of coke per mile or 2 lbs. per B.H.P. This, of course, is a good performance.

For hauling heavier loads it has been found convenient to employ a motor-car and a trailer, and it would seem that heavy goods can be very economically transported in this way so long as the speed is low. Judging from these trials we see no reason why those who are desirous of establishing a line of motor-vans between Liverpool and Manchester should not carry out their ideas without further delay. The roads between these two places are excellent and present none of the difficulties that characterised the Versailles routes. We trust, however, that those who are projecting the matter will not think it necessary to go abroad for their plant. Excellent as are the De Dion and Scotte tractors they present no novel or intricate details of construction, and similar tractors could be easily constructed by any engineering firm that possessed a reasonable amount of intelligence. Passing on to the oil motors, we need but remark that for vehicles ranging from the tricycle to the light omnibus and parcels vans oil motors may be usefully employed, but for vehicles intended to carry more than one ton they are distinctly unsuitable, at least in their present form. The great difficulty seems to be that as the power increases the weight increases in an increasing ratio, or, to use the language of mathematics, the

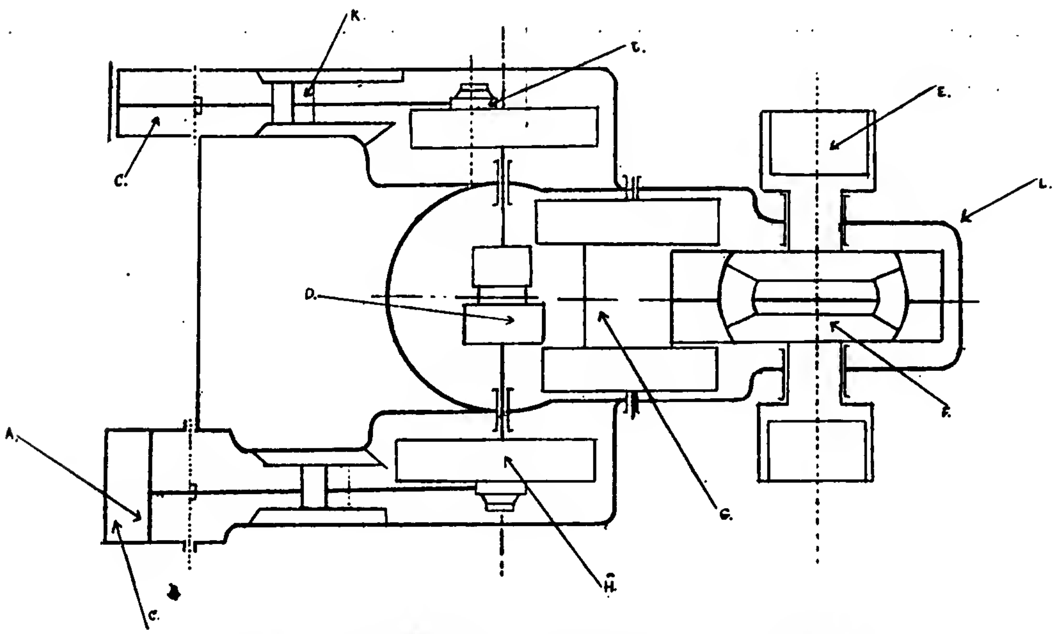
FIG. 4.—DE DION ET BOUTON STEAM TRACTOR.

FIG. 5.—DE DION ET BOUTON STEAM OMNIBUS.

weight does not follow a straight line law. In the matter of endurance it is difficult to express any opinion. In these trials there were not wanting signs by which it could be seen that most of the motors were being severely stressed. In our last month's issue we alluded to the strains produced on the wooden wheels. It is only right to say that in actual practice roads such as those around Versailles are the exception, and hence it is not altogether fair to regard them as typical. Finally another lesson taught by these trials is that the drivers in charge must be skilled men—not necessarily mechanics, but with sufficient *nous* to pack a gland, humour a feed-pump, and the like. A steam motor for road traction is after all but a modified locomotive and needs constant attention. Much of the success of the French trials was due to the watchfulness and technical knowledge of the drivers. On the whole the trials were a brilliant success, and all the arrangements were admirably carried out. We only hope that the British Automobile Club will before long furnish us with something equally instructive.

INSTITUTE OF BRITISH CARRIAGE MANUFACTURERS.

The Tenth Annual Autumn Conference of the above Incorporated Society was held at Southampton, on the 7th instant, under the presidency of Mr. Alexander Henderson, of Glasgow. In the course of his opening address the President said:—"The position you have placed me in is a very onerous one. However, having put my hand to the plough, I will strive to do my duty to the best of my ability in guiding the Councils of the Institute. I feel that the higher aims of our Institute can only be promoted by all of us becoming more closely and sympathetically bound in mutual intercourse, and by our working together as one body for a common cause, viz.:—'Carriage-building as a fine art and cultured profession,' and I shall, indeed, feel gratified if I can be the means of fostering such intercourse, and establishing a



Figs. 6 and 7.—Motor Mechanism, De Dion et Bouton Omnibus.

feeling of one interest and one cause among us. I would direct your attention for a few moments to one feature of our Queen's reign which is conspicuous to us all, and which has become an important factor in our daily lives; I allude to the great facilities for travel, due to the progress and improvement in locomotion of all kinds since the accession of Her Majesty. When Her Majesty succeeded her uncle, George Stephenson's immortal adaptation of steam to locomotion had been tentatively and successfully tried on various lines. Soon the capabilities and paramount advantages of the railway system burst upon the public, which, added to the ingrained desire of man to make money fast, speedily culminated in the great railway mania. Again, the rapid growth of London and our larger cities had stimulated the employment of street omnibuses, which appeared in great numbers, forming the basis of large companies and great proprietorships. Hansom's patent safety cab also came to stay, and, from its popularity, speedily became known as the hansom cab of the present day. By these means—suburban and underground railways, penny steamboats, and the omnipresent flitting cycle—our urban populations have such ready and cheap facilities as our forefathers never dreamt of.

"The question of technical education is, at the present time, receiving the careful attention of the Institute, for all interested in this most important subject feel that something must be done if we are to keep pace with our neighbours. I would suggest that we should, when taking on—employing—apprentices, bind them to attend technical classes, when such are available. It is, I say, the rising generation that is to stimulate us in our craft, and it behoves us to dower them with a sound technical, as well as a good general, education, if the carriage industry is to be one of prosperity and increase. Art and science must both be studied and introduced into our work, and by these factors we will produce more economically, more expeditiously, and more artistically, and will be enabled to compete with greater success in the open markets of the world. I wish very strongly to draw your attention to the scheme for higher education of coachbuilders, and commend to your serious consideration the letter which the Council has issued upon this subject. The Council hopes to receive sound, good, and valuable information by this means, that will enable them to be in a position to know if the establishment of a technical school for higher education will be taken advantage of. It will be a very great pity indeed if the facilities that have been offered to us by the London County Council and various other public bodies are not appreciated and profited from. The Coachmaker's Company, the London Chamber of Commerce, and the City and Guilds of London Institute, are all ready to co-operate with us.

"With regard to the motor-car, I suppose I am expected to say a few words, but to all those who have heard or read the former President's remarks, it will be apparent that little remains, from a coachbuilder's point, to be said. Mr. Jacobs referred to a friendly contest, or rather association, with autocars, and I beg to confirm his opinion. We, as coachbuilders, should, in the first place, be prepared to build a carriage for any motor that may be introduced. In the meantime, we build carriages for the horse as motor, and are required to produce vehicles for any sized pony or horse, from the 10 hands pony to the 17 hands horse; and I am very strongly of opinion that we cannot very well curtail our present position by giving way to any other special motor that may from time to time be introduced to us. We know that the motor carriage has been tried and experimented with on many occasions, but on every one of the many varieties some objectionable feature has been found fatal to its success and adoption as a vehicle for private use. Possibly, in course of time these defects may be removed, and a perfect and satisfactory motor result. I have no doubt but many clever mechanists are eagerly studying and striving to effect this, yet, however perfect the motor may eventually become, in my opinion, most people will still prefer, for private use, the life-like, animated appearance of well-appointed horse traction, to any dead mechanism, however smoothly it glides along. We should remain neutral, and be in a position to supply carriages for any motor that is introduced or required by a customer."

DOINGS OF PUBLIC COMPANIES.

The Epstein Electric Accumulator Company.

UNDER the winding-up of this Company the statutory meetings of creditors and contributories were held on the 10th instant, at the Board of Trade offices, Lincoln's Inn, and the Chairman reported that the Company was registered on July 31st, 1891, with a capital of £101,000, divided into 100,000 ordinary and 1,000 founders' shares of £1 each. The ordinary shares carried a preferential non-cumulative dividend of 15 per cent. per annum, and the holders of the founders' shares were to receive half of any profits after payment of such dividend. The Company was formed to acquire certain patents and patent rights relating to inventions and improvements for the manufacture and use of storage batteries, and to carry on the business of electrical engineers, the purchase price being fixed at £71,000. For some time Mr. Epstein acted as managing director, but latterly he was appointed consulting engineer, with a remuneration of £400 a year and £25 per annum for each 1 per cent. paid in dividend to the shareholders. The Company appeared to have been in want of funds throughout, and in March, 1893, debentures to the amount of £6,000 were issued to Woodhouse and Rawson United (Limited). In April, 1894, an arrangement was made whereby £12,000 second debentures were created, and a sum of £1,000 paid to the liquidator of Woodhouse and Rawson (Limited), the latter relieving the Company of its indebtedness to the extent of £13,000. The accounts which had been furnished showed liabilities £25,973, of which £18,826 were expected to rank, and assets (absorbed by claims of debenture-holders) £6,520. As regarded contributories, a deficiency of £90,153 was disclosed. Sir C. W. F. Crawford and Mr. Epstein, directors, expressed their conviction that the patents were still very valuable, and the proceedings resulted in the appointment of Mr. Northby (the Secretary of the Company) as liquidator.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles. We shall be pleased to reply with detailed particulars to inquiries through the "Answers to Correspondents" column. All communications should be addressed to the Editor. The only stipulation which we make is that where the inquiry involves a search of the records at Somerset House—as in the case of information on the subject of the holdings of shareholders—a postal order must be enclosed to cover the Government stamp of one shilling which is charged before a search is allowed to be made.]

THE Motor Development Corporation (Limited), of Tower Works, St. George's Square, Regent's Park, N.W., have secured the rights and obtained the services of Mr. F. F. Wellington and staff of the Indestructible Ignition Tube Syndicate (Limited) (now in liquidation), and is prepared to supply the Syndicate's customers with all goods as heretofore. We are informed that upwards of 9,000 of these ignition tubes have been sold.

Automobile Club of Great Britain.—A Company was registered under this title, No. 53,762, on August 16th, by Messrs. Lumley and Lumley, 37, Conduit Street, W., without articles of association, with a nominal capital of £100, in shares of £1 each. The Company is formed to establish and carry on a club, or clubs, in Great Britain, or other business calculated to directly or indirectly enhance the value of the Company's businesses, rights, or property; to sell the undertaking and property of the Company for such consideration as the directors may think fit; in particular for stocks, shares, debentures, or securities of any other Company having objects altogether or in part similar to this Company; to form any other Company for the purpose of acquiring all or any of the property and liabilities of this Company. The offices of the Company are 30, Moorgate Street, E.C.

Motor and Cycle Company of Ireland (Limited).

ON August 24th last, the directors and shareholders of the Motor and Cycle Company of Ireland (Limited) held an extraordinary general meeting at the offices, 10, Leinster Street, Dublin, for the purpose of considering and, if thought fit, passing the following resolution:—"That the Company be wound up voluntarily, and that Robert Gardner, Esq., be and is hereby appointed liquidator for the purpose of winding up."

The notice convening the meeting added that if the resolution were approved of it would be submitted for confirmation to a general meeting to be held at a future date.

The Right Hon. Alderman Meade presided.

The other directors present were—Right Hon. T. A. Dickson, Sir Howard Grubb, Mr. J. M. Inglis, with Mr. V. B. Dillon, solicitor to the Company.

Mr. R. M. MARTIN, the Secretary, read the notice convening the meeting.

The CHAIRMAN said:—Ladies and gentlemen, this is the first opportunity we have had of meeting those who were induced to apply for shares in the Motor-Cycle Company of Ireland. Before consenting to join the Company I had made inquiries as to the value of the Pennington motor, both as to its economical production, facility of working, and simplicity in action; and having inspected works at Coventry and also at Preston I was and am of opinion that it is the best motor in the market. I was also informed that large sums had been paid to Mr. Pennington for his patent rights in England, and on the whole I came to the conclusion that the securing for this country of the patent rights and the erection of a manufactory for the production in this city would be a desirable thing; that it would give considerable employment, and after a short time would be remunerative to the shareholders. The board was consequently formed, each member forming his own opinion, and not being influenced by any other. In making arrangements with Messrs. Pennington and Baines—Mr. Baines was joined in the scheme with Mr. Pennington—your directors made every arrangement for the safeguarding of the interests of the shareholders that they possibly could. It was stipulated that all the promotion money, advertising, and cost of registration—in fact, expenditure of any kind—should be borne and paid for by the promoters up to and including the allotment. It was also agreed that Mr. Pennington should act as managing director for three years, and it was arranged that he should reside here. It was also arranged that Mr. Pennington and the Pennington Motor Foreign Patent Syndicate should be paid in shares. On considering the amount it would be necessary to have in hand to build the factory and works, and equip them with the best machinery and plant, and have a sufficient sum for stock and opening business, £50,000 was considered adequate; and on April 7th we obtained a guarantee from Pennington and Baines undertaking to pay such a sum as would be required, in addition to the value of the shares applied for by the public, to make up the £50,000. Messrs. Pennington and Baines also handed us a written order from Mr. H. Lawson, of the British Motor Syndicate Company, for 500 motors at £150 each, and 500 motors at £110 each; thus for the 1,000 motors, about £130,000. We then issued the prospectus to the public, and as the result, 10,704 shares were allotted. Mr. Pennington had bought for the manufactory, tools and appliances in America, for which he paid 10,000 dollars. These, he informed us, he would have forwarded here as part payment of his first call on the 9,296 shares. We then went into the question of sites for the works, and, after exhaustive inquiries, selected one containing 27 acres of ground, facing London Bridge Road and the River Dodder, in the Pembroke Township, at a rent of £500 a year. As we were anxious to begin manufacturing at the earliest possible moment, we also made arrangements for the use of temporary works in which we could place the machines bought by Mr. Pennington, and we hoped that by this date we would have had motors completed and at work in the city. We had no reason to doubt this, as Mr. Pennington had attended all the board meetings, had inspected the sites offered, had acquiesced in the selection made, had given instructions for the plans of the new factory, had directed the alterations made at the temporary works, and had assured the board that he would have motors ready for work in 30 days after he could start at the temporary works. On May 22nd, for the first time, Mr. Pennington informed me that some difference had arisen between him and Messrs. Rucker and Lawson, to whom he had sold his patent rights, about the patents, and that his lawyers had the matter in hand. We have an agreement from the Pennington Foreign Motor Syndicate Company with an influential board, Sir Theodore Fry being chairman, to convey to us a license for Ireland of the patent rights under the two leading patents on or before June 30th; and as it was about these patents that the difficulties arose, I did not think but that the Company would have the licenses perfected in time. However, at a meeting of your board on June 1 a letter was read from Mr. Pennington stating that it would take some time to arrange the patent question, and that he had gone to America on private business, but would in five weeks' time be able to say when he would return. Needless to state your board was astonished at this communication, for at the time we had the plans nearly completed for the new factory, and were trying to arrange with the tenant in occupation of the ground at Sandymount for immediate possession. We held subsequently several meetings, at which Mr. Baines, and sometimes Mr. Carse, attended on Mr. Pennington's part, but ultimately they had to acknowledge that in the absence of Mr. Pennington they could not arrange matters. As up to this time the machinery had not been delivered, we pressed Mr. Baines for the payment of the £5,810 calls due on the 9,296 shares applied for by him and Mr. Pennington, but he did not lodge the money, and as we were always anxious that this matter should go through we consented to a delay for some time to give Mr. Baines an opportunity of going to America for Mr. Pennington, in consideration of which he (Mr. Baines) gave us an undertaking, in case the Company should be wound up voluntarily, that he would pay any liabilities the Company had incurred, so that the money could be returned to the shareholders in full. He went to the States and returned with Mr. Pennington. We had an interview with Mr. Pennington on the 6th inst., went through the whole matter with him, asked him was he then ready to pay in the £9,296, to hand us the license from the Pennington Motor Syndicate, and also the licenses from himself. He told us that he and Baines were equal partners, that he had his half of the £9,000 ready, but that he should see Baines about the other half, and that he thought there could be no difficulty about the patents. He asked us for another week to see Baines and arrange. We consented to this delay, and got an undertaking from him to pay the liabilities of the Company. We met again on the 12th inst., and as we had not had a satisfactory reply from Pennington we resolved to call you together. We have not lost faith in the future of the motor-cycle, which we feel will be successful, but we cannot recommend you to undertake the necessary expenditure required in building and equipping a factory and works for the manufacture of the Pennington cycle, under the conditions which now obtain. As regards the sums paid in by shareholders, the total amount lodged in the Hibernian Bank was £26,061, of which we have on deposit £24,500; to credit of current account, £1,459; and we have paid for office furniture, for a safe and sundries, £102; making in all £26,061. I have now, ladies and gentlemen, to move, which I do with very great regret, "That the Company be wound up voluntarily, and that Robert Gardner, of 40 and 41, Dame Street, be and is hereby appointed liquidator for the purposes of winding up."

Mr. J. MALCOLM INGLIS, J.P., in seconding the resolution, said under the circumstances he thought the best thing they could do was to wind up the Company.

Mr. ROBERT DUFF rose to move that the meeting be adjourned for a fortnight to enable them to inquire into the *modus operandi* in which the directors had conducted the business and whether Mr. Pennington was clever enough to put his finger in the directors' eyes. He (Mr. Duff) held over £1,000 worth of shares, and he submitted that the shareholders had a right to a fuller explanation than that vouchsafed by the chairman. He knew perfectly well that it was a Yankee dodge. (Hear, hear.) He wanted to know who was to pay the liquidator? Was it the shareholders? Did the chairman know anything at all about Mr. Robert Gardner, or how long it took to wind up a company and the expense of it? It was nothing less than culpable that information had been withheld from the shareholders—they had heard nothing. There had been inspired paragraphs in the papers with reference to the Company, and to Mr. Pennington living at the rate of a thousand pounds for a couple of months, and all this high-falutin talk. What was the result? Put your hands in your pockets and pay for it. What guarantee had they for Mr. Pennington that he would pay up? Had they any?

Mr. DUFF, who then explained that he was acting as chairman of the Shareholders' Protection Association, submitted to the chairman a copy of a series of questions he had prepared on behalf of the association, and asked was Mr. Pennington at that meeting?

The CHAIRMAN: He is not.

Mr. DUFF thought it would be better to form a shareholders' committee to liquidate and save the Company as much expense as possible, and finished by moving the adjournment of the meeting for a fortnight in order that a committee of shareholders should inquire into the affairs of the Company.

Replying to questions, the CHAIRMAN said there was a provisional agreement with the Company to take the Pembroke Township site for 56 years at £500 per annum and expend £2,000 on the buildings.

Mr. THOMPSON (Longford) said he did not think it would be desirable in the interests of the shareholders to either adjourn that meeting or postpone carrying out the recommendations of the chairman. There was no use in dragging the thing on. Their interests would be the worse off the longer they postponed the matter.

The amendment was not seconded.

The CHAIRMAN said there was nothing further from the wishes or desires of the directors than to withhold the slightest information from the shareholders. It came on the directors themselves like a bolt from the blue when they got Mr. Pennington's letter in June. Up to that Mr. Pennington showed himself to be a man of large and undoubted means—he had a large sum to his credit in one of the leading banks in Dublin, and it was only before leaving Dublin that he withdrew that sum. They believed the guarantee of these two gentlemen to be good, and they could not say more. Up to the present moment they had expended £102, and that was for the office and safe. The directors would be very glad indeed if the shareholders named two or three gentlemen to act with the board in getting the Company wound up most economically. (Hear, hear.) As to the cost of liquidation no one could do it so cheaply as Mr. Gardner, because he had all the documents in connection with the Company in his possession. He thanked the gentlemen who had spoken so well of the directors. They formed the best opinion and made the best bargain they could. The expenses that had to be met by Mr. Pennington and the promoters came roughly to between £9,000 and £10,000; the shareholders had not to pay one shilling of it, and any liabilities there were would be in connection with the field. The other liabilities were infinitesimal. He thought the amount of interest on the deposit account would cover everything, except what there might be for that field, and he (the chairman), knowing the neighbourhood of Sandymount so well, thought there was very little liability in that. (Applause.) They had done all they could, they had got a guarantee from Mr. Baines, who was a man that made in the last three or four years £30,000 in England, and Mr. Pennington was a man of means if they get hold of it. (Laughter.) He would ask them to adopt the resolution he had proposed. You will get the first payment in a month. We want the thing wound up. We feel that we have been "had." We feel very bitterly the position we have to occupy here before you to-day. Some of us thought we knew something about business, and that we were not so easily taken in as unfortunately we have been in this transaction. I need not tell you it is not a pleasant position for us to stand in now.

Mr. KINSELLA asked how Mr. Gardner came to have the documents in reference to the Company?

The CHAIRMAN: He has got the shareholders' lists and everything, because Mr. Gardner was retained by Mr. Pennington and paid by him.

Mr. GARDNER: No, unfortunately. (Laughter.) It was only a promise. (Laughter.)

The CHAIRMAN: Mr. Gardner was retained by Mr. Pennington and told he would be paid. Unfortunately, he says, he is not paid. He has all the books, the register of shareholders, and everything else, and. for all that, we have not to pay a penny, and we have the advantage and use of them. This is the reason I say no one can liquidate the Company so economically as Mr. Gardner, and, in addition to that, you have the amount of his remuneration in your own hands.

The resolution was put and carried, with one dissentient.

The CHAIRMAN then proposed, and it was resolved, that a committee be appointed, consisting of the following shareholders:—Mr. William Fry, Mr. Coleman, Sir Percy Grace, Mr. Ledwich, Mr. Thompson, and Mr. Kinsella, to act with two directors in the winding up of the Company.

The proceedings then concluded.

Electric Traction in Spain.—Although some of the Liverpool City fathers seem to think it necessary to engage an American traction engineer to lay and work some four miles of track, other, and possibly more enlightened, municipal authorities think, and rightly so, that British engineers can do all that American or other engineers can. We are glad to note that Messrs. Dick, Kerr, and Co. (Limited), have just contracted with the municipalities of Madrid and Barcelona to build and equip most extensive electric tramways for those cities. The contract runs into something like £160,000, and is said to be the biggest tramway contract ever yet made. We may be sure that before placing it the Spanish authorities satisfied themselves that the firm in question was quite competent to carry it through, both from the technical and commercial points of view.

British Industries and Foreign Competition.—It is rumoured that the London and North-Western Railway Company is in treaty for the delivery of 100,000 tons of steel rails from the United States, and, considering the low prices and cheap freights that rule at present, there appears to be nothing improbable, though there is a great deal that is disquieting, in this report. Our manufacturers have lost the large rail contracts for Canadian main railways, in which we appeared to possess a prescriptive right; and recently an order for 4,000 tons for this country, required by Mr. R. W. Blackwell, of 39, Victoria Street, was secured by an American firm by the right of price and promptness of delivery, the quality, of course, being secured by a rigid specification. Only a short time since another order for rails for an English line was also lost by our manufacturers, not to the United States, but to Germany; in this case, however, the rail-makers had to lower their price more than 20*s.* a ton to secure the contract; here price and promptness of delivery placed our manufacturers out of competition. But it is not only in rails that the war of competition—which, from a pessimistic point of view, may gradually develop into a war of extermination—is now raging. We appear to be growing (says *Engineering*) more and more dependent on American machine tool-makers; indeed, it is not an exaggeration to say that during the now vanishing period of depression in the United States many once prosperous engineers' works must have been closed but for the never-failing support from Europe. We are dependent on the United States to build the elevators for the Central London Railway, and we have to look to the other side of the Atlantic for the electrical plant with which the traffic is to be worked. It is notorious that we are unable properly to equip an electrically-worked tramway, and that until our manufacturers take the trouble to learn how, the large and increasing contracts for this new industry must be taken by Americans. Now that so many employers of labour are suffering from enforced idleness by a ruinous strike, they may find time to learn why we, who still blindly call ourselves the leading industrial nation of the world, are content to close our eyes to what is going on around us, and to realise our dangers before it is too late to recover, at least to some extent, the undoubted pre-eminence we once enjoyed.

CORRESPONDENCE.

*** *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

THE RULE OF THE ROAD.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—In September last I wrote a letter to the *Times* regarding the "Rules of the Road," and I venture now to address you on the same subject.

I never "scorch" or "boast," nevertheless, when I am on my bicycle I find pedestrians my *bêtes noires*, for whether passing them or overtaking them there is a doubt to the last moment as to which side of the road they will take. This is all owing to uncertainty regarding "rules of the road." Pedestrian meeting pedestrian is, I believe, expected to keep to the right, but this rule cannot be general, for I have seen in London a notice in one place for pedestrians to keep to the right, and in another they were asked to keep to the left. At all events there is absolutely no rule whatever between pedestrians and riders, consequently when a man walking meets another riding neither of them know what to do. When the "rules of the road" were originated there may have been very good reasons requiring pedestrians to keep to the right and riders to the left, but it does not matter one brass farthing *now* how wise these riders were in antediluvian days.

What has to be considered is the present time, when vehicles have increased tenfold, or more correctly, perhaps, one hundred-fold, to what they were 50 years ago. It will be admitted as an axiom by everyone that it is easier to learn and retain in memory *one* "rule of the road" than *two*. Why, therefore, cannot one "rule of the road" be adopted for all? It would, I am sure, save many a coroner's inquest if one rule were adopted and instilled into the rising generation.

I was glad to see that Mr. A. R. Sennett in his interesting work, "Carriages Without Horses Shall Go," advocates one rule for all. As he is a distinguished civil engineer, and is on the Council of the Self-Propelled Traffic Association, no doubt his suggestion will carry weight, but when any evil has to be corrected or any arrangement adopted for benefiting the public, we Britons instinctively look to the Press to carry it out; therefore, if you, Sir, will take up the cudgels and insist on County Councils and others in authority adopting one "rule of the road" for *all*, with the circulation THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL has, success must follow.—Yours faithfully, J. R. MAGRATH (*Colonel*).

[We think that the rule of the road for all pedestrians and riders should be the same as the rule of the road at sea, that is:—"When meeting end on, or nearly end on, so as to involve risk of collision, each should direct their course to (the right) starboard." We are glad to see that the London County Council is trying to enforce this rule at the Blackwall Tunnel. —ED.]

Re THE BRITISH MOTOR SYNDICATE (LIMITED).

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

DEAR SIR,—I think it only courtesy to inform you that the shareholders I acted for in the above matter did not see their way clear to join the suggested combination (which I understand is now actively proceeding), but preferred to accept the Company's offer to take over half of their holding immediately at £2 10*s.* per share with an undertaking to take the balance in three months' time at £2 15*s.* per share.

Fortunately this arrangement was legally carried out, as although the first half was taken up at the smaller figure it required an enormous amount of leverage to induce the Company to take the remainder at the higher price, and it was actually not until proceedings were taken in some of the cases to compel them that the matters were settled.

Meantime I am sure my clients (one of whom you will be interested to learn is a school teacher, whose practically entire savings of a lifetime were represented in this, his first investment in stocks or shares) will be grateful to you for your crusade in the matter, as it is probably owing to that that they have been enabled to substantially minimise their loss. The shares I understand at the present moment stand considerably lower on the market.—Yours faithfully, EDWIN E. CLARK.

61, King William Street, London, E.C.

COUPLED WHEELS FOR ROAD ENGINES.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—I should be glad if you could give an opinion in your next issue on the following points in reference to the use of coupled driving wheels for road locomotion :—

(1) Would the coupling of two pairs of driving wheels (somewhat as in a locomotive) interfere seriously with the steering of a road vehicle owing to the axles not being radial?

(2) How far would this depend on the speed of the vehicle?

In railway work the rigid wheel base may be considerable, and might not be objectionable *within reduced limits* for ordinary roads. See enclosed rough sketch of arrangement proposed, the car being long so as to give ample distance between coupled drivers and steering wheel. It seems to me a pity that experiments to investigate various points arising from the new conditions of locomotion have not been projected by any competent body, makers being afraid apparently to depart from horse-drawn lines. By throwing the weight of the engine and a good part of the load on to two pairs of driving wheels considerable adhesion will be obtained without undue clumsiness (*e.g.*, very broad wheels), a matter of some importance in view of the fact that on country roads (for farm work, &c.) a second laden vehicle will be required to be drawn.

Another field for heavy steam traffic seems to be the provision of passenger coaches to serve districts not traversed by railways, and it has occurred to me that much of the clumsy appearance complained of in steam cars would be relieved by the use of two axles in close contiguity.

The arrangement suggested would certainly prevent the use of very large driving wheels without, it is hoped, entailing the use of castors, which, to judge by this month's illustrations in the AUTOMOTOR, find favour with some manufacturers, I suppose on the score of strength.

In the sketch I have placed the steering wheels *behind*, not only because an obstruction in the road would be less likely to disconcert the heavily-weighted and less easily twisted driving wheels, but in order that the driver may be placed in front with the machinery under his observation. In this connection the question may be asked :—

(3) Would there be any difficulty in hauling a second vehicle with this arrangement (rear-steering)?

Apologising for troubling you at such length.—I am, yours very truly, LOCO.

[It would not be practicable to couple the wheels of a road tractor because (*a*) the connection could not be rendered sufficiently flexible to allow for inequalities in the road; (*b*) because such a vehicle could not be steered—at any rate round curves of small radius such as are found when turning a street corner, and also because, owing to the great adhesion on common roads, the slipping action of the inner wheels which takes place in the case of a locomotive would not occur. In our opinion a rigid wheel base for road tractors is utterly out of the question for the foregoing reasons. On a railway the vehicle is steered by the rails, and such steering or rather guiding can only be accomplished by using curves of large radius. Even as it is the arrangement is far from being a mechanically perfect one. With regard to the suggestion raised by our correspondent we agree that the subject of road traction might well be scientifically investigated. There is a deplorable absence of reliable data. Rear steering would not, we think, be mechanically or theoretically a good arrangement for tractors. Were it so, we might be sure that Aveling, Burrell, and other makers would have adopted it.—ED.]

SIR,—Excuse my adding a supplementary note to my recent communication. It has occurred to me that in assuming the two pairs of driving wheels to be coupled together *rigidly* (as in a locomotive) I was, perhaps, giving undue importance to simplicity of construction. Considering that the desirable arrangement of direct driving is out of the question, it seems possible that a slight radial play to, say, the rear-drivers, might be given without undue increase of complication—*rear* drivers, as it seems better that the wheels encountering any large obstruction should be rigid besides being furnished with a guard. If you could touch on this point in your answer I should be obliged.—I am, yours very truly, LOCO.

P.S.—The arrangement, as you will have noticed, is really nothing more than a locomotive and truck fused into one.

[We have replied to this in the former letter.—ED.]

PRESSURE IN GAS AND OIL ENGINES.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Can you oblige me with the following information, viz., What is the pressure in lbs. per square inch that the calculation of horse-power of a gas or oil engine is calculated by? I know this will vary according to mixtures and compression; but say about with the best and most perfect mixture with three and four atmospheric compressions. To make my request clearer I will put it another way :—What is the average pressure on a moving piston when an engine is working at its best? An answer in your next journal will suffice and oblige.—Yours truly, GAS.

[Taking a Crossley Otto gas-engine as a typical internal combustion motor, the mean initial pressure on full load was in a certain trial 196 lbs. per square inch; the mean effective pressure was 68 lbs. per square inch. Taking the Pristman oil-engine as a typical oil-motor, the mean pressure is about 55 lbs. per square inch.—ED.]

THE CHOICE OF A MOTOR-CAR.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—I should esteem it a favour if you would kindly answer me a few questions with a view to guiding me in the selection of a motor-carriage. I am a country doctor of limited means, and shall probably remain in that undesirable condition until I can abolish an expensive stable. I am, therefore, *very anxious indeed* to try a motor-carriage. My work averages about 5,000 miles a year, and during four months the roads are smothered at intervals with broken slag or granite. I want an inexpensive carriage, to carry two, which will run at an average of 10 or 12 miles an hour and mount a hill of one in 10 with tolerable ease, and steeper one at a pinch.

(1.) What carriage do you advise? From inquiries I have made, already my choice appears to lie between a small Benz carriage and Bollée tandem (Coventry motette). I should prefer the former for comfort, inasmuch as one could wrap up in inclement weather and also because the tyres are not pneumatic and will probably stand the stones better, but I am told the electric ignition is a drawback and the motor is not sufficiently powerful for my purpose.

(2.) Am I right in choosing the Bollée in preference to the other on these grounds alone? I find that the Yorkshire Motor-

Car Company (Mr. J. E. Tuke) will sell a car on the hire-purchase system.

(3.) Do you advise me against this? They want £15 a month for any carriage. Now this would be a terribly heavy strain on me, nevertheless I will try it as it promises to repay me well if I get a carriage. This being the case—

(4.) Would you advise me to go in for one of the more expensive carriages at about £350 while I am at it, or shall I content myself with a cheaper one until I see what another year may bring forth?

(5.) Finally, would you advise me to wait until, say, next spring before purchasing?

I appeal to you, Sir, as an honest adviser who will give me a disinterested and candid opinion, and one which I may take as being final and which I intend to follow if I am able. Thanking you in anticipation and as an old subscriber to your paper.—I beg to remain, yours faithfully, NUMBER ONE.

P.S.—I enclose my card.

[(1.) To climb 10 per cent. gradients and over ou roads composed of slag and granite cubes at a fair speed means the employment of a powerful and substantial motor with iron tyres. As you will see, it would be invidious on our part to recommend any particular motor. Your best plan is to consult an engineer who makes these matters his business. (2.) The Bollée is a reliable motor, but would hardly stand prolonged wear on a slag and granite road. (3.) We see no reason to advise you against this course. (4.) Speaking generally, we should advise you to obtain good professional advice and purchase a motor-carriage with which the makers will give a guarantee. No great improvement in light oil motors is to be anticipated in the near future. (5.) We see no necessity.—ED.]

BENZINE.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Will you kindly answer in your next issue of the AUTOMOTOR and oblige:—

(1.) Does benzine require heat to vaporise it for use in oil-engines, or is it sufficient to have, say, two quarts of benzine in tank without any heat whatever?

(2.) Will a motor-cycle run (with benzine) without any water cooling to cylinder, the cylinders are steel tubing ⅛ inch thick?—Yours, &c., F. C.

[(1.) At ordinary temperatures benzine will slowly evaporate if exposed to the air. If in a closed tank partially filled, the space above the oil will consist of a saturated vapour. For use in an engine the evaporation must be very rapid and continuous, therefore great heat is necessary. (2.) Generally it will, providing the external temperature is low, and that the air is in motion; it is, however, best to provide radiators.—ED.]

LONDON ELECTRICAL CAB COMPANY (LIMITED).

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

DEAR SIR,—It may interest your readers to have a few particulars of the working of the electrical cabs since the inauguration on August 19th last.

I may say that so far everything has been most successful, and the fact that the Scotland Yard authorities, after having refused licenses to several other kinds of motor-carriages, have, after a severe test, duly licensed the cabs, is in itself a proof of their efficiency.

A part of the Scotland Yard test is to run each cab up and down the Savoy Hill, in the Strand, this hill being the steepest gradient in London.

At different times, and on several occasions, journeys have been made to and from Hampton Court, Kempton Park, Lewisham, Sandown Park, Norwood, Croydon, Crystal Palace, Crouch End, &c., and the steep hills to be met with on some of the roads running to these various places, such as Highgate Hill, Sydenham Hill, and Richmond Hill, have given no trouble whatever.

Further, twelve of the cabs have been plying for hire in and around the City and the West End of London, and the takings of the cabmen—amounting as they do to about 150 per cent. more than the takings of an ordinary hansom—show very well the public favour with which the cabs have been received.

With regard to the "opposition" of the London Cab Trade Council, which numbers some 50 or 60 members, we have to place side by side the fact that the great Cab Drivers' Union of London, numbering some 10,000 members, are distinctly in favour of the new cab.

Thanking you in advance for the courtesy which admits this letter to your valuable columns.—Yours faithfully,

WALTER C. BERSEY,
September 11th, 1897. General Manager.

Cabby on Motors.—For good undiluted fine old real-crusted conservatism you cannot possibly beat a London cabman. And just as his prototypes of the early days of the century denounced the locomotive because it would ruin the breed of "'osses," so the modern cabby denounces motor-cars, because he by some process of mental exercise has concluded that the motor-car will spoil his business. To tell cabby that by lessening the cost of working a vehicle it will be more used and yield more profit, is to preach to ears hopelessly closed by preconceived assertion and unintelligent dogma. Hence it is not surprising to find the London Cab Trade Council in a recent meeting fully acting up to their natural instincts. One gentleman is reported to have said that "at the present moment the price of a cab had reached the maximum, and it was impossible for cab drivers to bear any further burden in the shape of enhanced prices, as would be the case if drivers entered into even the mildest form of competition for the new cabs." Now, as a matter of ordinary supply and demand, it would follow that the introduction of better vehicles would be followed by a reduction in the price of the hire of the ordinary cabs, and this would be most likely followed by better profits being earned by cabmen generally, simply because their prices are fixed by authority and cannot be altered. Hence the motor-cab is really a friend to the cabman, but hardly so to the ordinary cab proprietor. Ultimately the following resolution was passed:—"That this Council meeting views with disapproval the introduction of electric cabs on the streets of London, and urges all cab drivers, in the interests of the cab industry, to discourage any further development of public vehicles driven by motive power." We do not think that this resolution means anything more serious than the sounding brass and the tinkling cymbals of the uninstructed. It has pleased these gentlemen to pass it, but that it will in any way hinder the development of a promising industry we do not for one moment believe. There is no doubt a good deal to be said from the cabman's point of view against the introduction of horseless vehicles, but much more in favour of the innovation. The new vehicles will require a more careful and intelligent body of drivers, a thing desirable in itself. At present the London cabby is not a favourite with the public. Long association with horses does not, as a rule, tend to that suavity of manners so desirable in those who serve the public, and in this respect it must be confessed that the cabby is deficient; whereas under the new system it will be possible to ensure civility and strictly legal charges. The better class of cabmen recognise that the new cabs will benefit them. Mr. W. Bersey says, in a letter to the Press:—"We have spoken to hundreds of cabmen on the subject, and have always understood they were most anxious for the change, as it would shorten their hours—by saving the time wasted in changing horses—and also save them the unpleasantness of frequently having to drive tired and undesirable horses. I may add that we have no intention of charging the drivers more than the prices they now have to pay."

REVIEWS OF BOOKS.

"The Motor-Cycle and Component Parts Official Intelligence." (London: Effingham Wilson and Co., Royal Exchange.) Price 5*s*.

THIS is a kind of cycle "Burdett," and, looking through it with some knowledge of the trade, one can gather some curious and possibly useful information. The particulars are taken from official sources, and include authorised capital, shares, purchase money, form of transfer, method of voting, date of making up accounts, latest price up to time of going to press, list of directors and officers, address, &c. As we say, this information is in some cases decidedly curious, and one realises how tremendously large is the capital sunk in the cycle industry, although it is disheartening to see how few cycle companies' shares stand at even par value. It would seem that directly any intelligent mechanic or clerk who rides a "bike" to his shop, and discovers that by twisting a bit here and adding a piece there, or putting in or taking out a screw he effects what he calls an "improvement," he forthwith proceeds to patent his "invention" (*sic*), and the public gives him anything from £5,000 to £50,000 for it, of which he may possibly get £500 as his share of the spoil. As for the silly investors, they deservedly lose by the precious "investment." This book contains many such instances of cycle companies whose shares are all but worthless, and whose property in patents is valueless. While the information given is good so far as it goes, we would suggest that the public and private addresses of directors should in all cases be given, together with any other information, such as their ostensible position, business, &c. As regards the particular industry which we represent, viz., the automotor industry, our previous remarks apply, with the exception that a number of omissions might be pointed out. At the end of the work is a list of names of dealers, agents, and manufacturers—a somewhat superfluous addition, and of little value, as it is not classified. The book is decidedly useful, notwithstanding its shortcomings. It needs extension.

"The Calculus for Engineers." By PROFESSOR PERRY, M.E., D.Sc., F.R.S., &c. (Edward Arnold, 37, Bedford Street, London, and 70, Fifth Avenue, New York.)

PROFESSOR PERRY occupies such a deservedly high place as an exponent of the science of engineering that a criticism of any work he may publish is, to all but the most advanced and captious critics, supererogatory. It is sufficient to say that the work in question is by one of the half dozen or so really scientific engineers that we know of. When we studied the calculus under the rigorously academic system of Todhunter we often asked ourselves *Cui bono?* In that classical work, which by the way is by no means superseded by that before us, the student rarely saw the end of his labours, and although a study of Todhunter rendered him a good mathematician, it did not give him much assistance in solving the problems of professional practice, whether this took the shape of civil, military, marine, or nautical engineering; we use the latter term advisedly. There is hardly any profession involving the use of figures to which a knowledge of the calculus may not be usefully applied. The accountant for instance, who analyses balance sheets, is not usually aware that the calculus would enable him to, in many cases, greatly facilitate his work. Similarly the navigator is not aware that he daily employs it. Professor Perry has attacked his subject in a decidedly original and successful manner. As an instructor in engineering at the Finsbury Technical College, he has had abundant opportunities of knowing the difficulties that students experience when taking up the calculus for the first time and hence the present work is largely explanatory and this gives it its great value, which is not lessened by the colloquial style adopted. Commencing with graphics the Professor shows how to put such equations as $y = ax^n$ and $y = a \sin (bx + c)$ in the form of curves. Professor Perry attaches very great importance to the employment of curves as representing the law governing some phenomenon and we quite agree with his view. Indeed the calculus can hardly be appreciated without the aid of graphics; squared paper is as the Professor points out only sevenpence a quire (our stationer charges us more). From these introductory exercises we are led up to a consideration of that rock of offence to so many students $\frac{dy}{dx}$; this is carefully explained as a rate or slope, and it may be as well to point out that it does *not* mean $\frac{d \times y}{d \times x}$, neither does δt mean $\delta \times t$.

In our author's hands the doctrine of limits is lucidly explained. In studying, he gives this advice, "Get as little help from teachers as possible, but help from fellow-students will be very useful, especially if it leads to wrangling about the subject." All who have had class or lecture-room experience will recognise the truth of this. The subjects of slope and speed, acceleration, and motion generally are ably and interestingly handled, and many practical examples of the application of this elementary part of the calculus are given. We notice that the Professor does all his thinking in ordinary units, such as pounds, feet, and seconds; the poundal is an abomination to him as to us. By easy and pleasant stages we are shown how to differentiate ax^2, and are then introduced to that terror of our student days, $\int x^m . dx$. In the Professor's hands this formidable symbol becomes quite harmless and turns out to be nothing more than a useful little dodge of performing difficult addition. We then come to maxima and minima, and it is surprising to learn to how many problems in daily life the calculus can be usefully applied. For instance—What is the largest sized box that may be sent through the Parcels Post? The regulations merely say that the length *plus* girth must not exceed six feet; this can, of course, be solved by a trial and error process of arithmetic, but it really is an example of maxima and minima, as is the somewhat analogous problem of finding the best conductor for a given current of electricity. The areas of curves and the application of the calculus to geometry are then dealt with, and this is succeeded by some useful sections dealing with the strength of cylinders, beams, bending, girders, &c. In all these the engineer will find many obscure things elucidated. Chapter II commences with an exposition of what is known as the Compound Interest Law, which, as the Professor points out, has a very wide application throughout Nature. He illustrates it by the leakage of an electric condenser and the slipping of a belt on a pulley. Space forbids us to dwell longer on this, to us, fascinating book. Professor Perry combines what is very rarely the case, the academic and the practical; his range of knowledge is immense, and there seems to be hardly a problem in physics that he cannot solve with the aid of the calculus. At the same time the Professor, with all his learning, is still very human, and throughout this work there runs a vein of latent humour which gives it an additional interest. For instance, what student will not rejoice to be told that "he may skip judiciously," and that he is to work up no problem in which he has no professional interest; and again, "men who think they know a little about this subject already, will not care to take the trouble, and if you do not find yourself interested, I advise you not to take the trouble either." We are pleased to hear that the Professor has another work in hand dealing with engineering problems of a higher order than is treated of in this book. We can only recommend the latter as being not only a useful tool in the hands of the intelligent engineer, but also as an elegant mental tonic for everyone who has a natural taste for mathematics.

"Cassier's Magazine."

OF the vast number of magazines that are published, few, if any, can claim to equal, either in bulk, illustrations, or intellectual value the marine number of *Cassier's Magazine*. Magazine! Why, it is more properly a treatise on Naval Science brought up to date, and yet not so scientific but that its contents can be read with advantage by any intelligent person who takes an interest in marine affairs. In the present number are 17 articles, all the writers of which are acknowledged experts in their various ways. Sir W. H. White, R.N., F.R.S., our Chief Constructor, contributes a gracefully-written essay on specialities of warship design. In this he traces the evolution of our navy, and describes the nature of the problems that the naval architect has to solve. Not a small part of Sir W. H. White's literary work has been devoted to correcting popular errors about our warships. In the House of Commons and on the Press are numbers of persons who have never designed, nor could design, anything, and who have never kept a watch in charge of a vessel. These persons are, therefore, authorities on naval matters, and it is they who oracularly say, "She is too short," or "too long," or too anything. In the present paper Sir W. H. White deals with these critics kindly but effectively. Thus :—"In some quarters, whatever length may be decided on, it is pronounced to be '50 feet too short,' as a rule, without any investigation of what such an addition would involve. Where criticisms have been associated with alternative proposals—and such cases are few—it has been the writer's task to investigate them. In no single case so treated has it appeared that the proposals made would have given the gains in propulsion anticipated in association with other supposed advantages. As a rule, the proposals made have been proved to be incompatible with a due provision of stability." The article abounds in figures and data which, considering the position of the writer, may be accepted as official. To all interested in naval affairs we strongly recommend a perusal of this and the succeeding article on fast torpedo-boats by Mr. A. F. Yarrow, the well-known builder, and, let us add, one of the pioneers of automobilism. This article is also historical and descriptive, technical enough to supply some useful data, and popular enough to make interesting reading. The speed and power curve is distinctly useful. Thus a first-class torpedo-boat requires about 450 I.H.P. to drive her at 15 knots ; 1,050 to drive her at 20; 2,150 to drive her at 25, and 4,400 to drive her at nearly 30 knots. In other words, to double the speed of 15 knots requires roughly 10 times the power.

The "Problem of Steamship Design" has occupied the pen of Mr. H. H. West, M.I.N.A., of Liverpool, a well-known naval architect who is the designer of the new Isle of Man steamer, one of the fastest paddle-boats in the world, and who attended with us the Paris heavy motor-car trials as a delegate from the Self-Propelled Traffic Association. Mr. West confines his attention chiefly to the larger class of merchant ships, of which he has designed a great many. He, like his more distinguished colleague, Sir W. H. White, has often cause to complain that the scientific disposition of weights is sadly interfered with by the necessities of the case. His article forms a useful account of modern shipbuilding.

Of a more scientific character is the article by Mr. R. Caird, on the "Launching of a Ship." Mr. Caird is a member of the historic firm of Cairds, of Greenock, who have built nearly all the P. and O. steamers. Launching a vessel is a process that involves tremendous responsibility, great anxiety, and months of careful preparation, and great cost ; a bad launch may ruin a firm. Instances are not lacking. The writer of this review could mention a few. The process of launching occupies less than a minute, but during that time a very interesting dynamical problem is being solved.

"Principles" affecting a floating ship, by Mr. F. P. Purvis, is an extremely useful essay which we can recommend to the student and seaman, and even to the professional naval architect. We have never seen the obscure laws of ships' resistance so ably put forth and explained as is done here. His remarks on the cutical speeds of steamships seem to us to be especially valuable. Mr. Purvis is or was, if we mistake not, a member of the scientific staff of that very scientific firm of shipbuilders, Messrs. Denny, of Dumbarton, one of whom, Mr. A. Denny, contributes a capital article on the "Design and Building of a Steamship." Needless to say that this is worth more than hasty reading. The whole process of building, from the ordering of the plates to the trial trip, are pleasantly explained. Naturally Mr. Denny has a shot at his old enemy the Admiralty Constant, and he quietly bewails how the hands of the advanced shipbuilder are tied by unsympathetic and prosaic bodies like Lloyd's.

"Marine Boiler Furnaces," by Mr. D. B. Morison, is an account of the manufacture of this important part of a cylindrical or Scotch boiler. As is well known, Mr. Morison is the inventor of a furnace which is an evoluted Fox's flue. He has a good deal to say about the operation of the Board of Trade rules, and points out their unscientific character. We should like to hear Mr. Morison on water-tube boilers.

Mr. John Thornycroft contributes an article on "Steamers for Shallow Rivers," and in this he explains the advantages of the turbine propeller.

So far we have only gone a third through the magazine, and consideration of space compels us to bring our remarks to a close. Other articles and their writers are :—"Water-Tube Boilers for War Vessels," by Walter M. McFarland, U.S.N. ; "The Naval Weakness of Great Britain," by Sir Charles W. Dilke, Bart., M.P. ; "The Modern Marine Engine," by Charles E. Hyde ; "American Sound and River Steamboats," by Leander N. Lovell ; "The Auxiliary Machinery of an American Warship," by F. Meriam Wheeler ; "Shipbuilding and Transportation on the Great American Lakes," by Joseph R. Oldham, N.A. ; "Steel for Marine Engine Forgings and Shaftings," by R. W. Davenport, M. Am. Inst. M.E. ; "The Coaling of Steamships," by S. Howard Smith ; and "Submarine Navigation," by John P. Holland.

Each and all these articles are more than good, they are worth careful study. We can only congratulate the proprietors and the editor of *Cassier's* on the production of a magazine that is simply brimful of the best information. It is a wonderful production, and no writer on naval or marine matters can afford to miss this work. Not only are the literary contents of the highest value, but the illustrations are extremely good, while the paper and printing leave nothing to be desired. We should not omit to mention that the likenesses of the writers of the articles are excellent and worth preserving.

Catalogues.

The Worthington Pump Company, of New York and London send us an exceedingly well illustrated handbook descriptive of their well-known pumps, condensers, &c. Probably no steam motor is more widely used than the Worthington pump. It was the "master" duplex pump, and although it has been widely copied and imitated both in England and America, we, who have used pumps a good deal, are not aware that the Worthington has been much, if at all, improved. In the present catalogue will be found many new variants and modifications of the original type. There is a good descriptive letter-press and telegraphic code list ; the latter enabling a purchaser to state in a single word what would otherwise occupy reams of specification paper.

Messrs. Chas. Burrell and Sons (Limited), of Thetford, send us their illustrated catalogue of road locomotives. We need hardly say that this old-established firm (it dates from 1770) has gained a world-wide reputation for high class mechanism. In the present catalogue, which, by the way, is copiously illustrated, the farmer, contractor, municipal or military engineer will find many examples applicable to their special requirements. We observe that a unique speciality of this firm is the supply of tractors for hauling the plant of circus proprietors. It is not generally known that the country circus proprietor is a good customer to the engineer, and much money is spent in this direction. Messrs. Burrell make an excellent road engine, which not only drives the circus, but supplies the electric light, and, when the show is over, hauls the whole concern to the next town. Among other machines we may mention portable and semi-portable engines which burn either coal, wood, or straw ; ploughs for English, Indian, or colonial requirements ; traction trucks, threshing machines, &c. In short, this is an excellent catalogue and contains an abundance of really useful information—the result of this firm's extensive experience.

The Clayton Air Compressors.—We have received from the Clayton Company, of New York, a well got up and well illustrated catalogue, or, rather, handbook of their specialities in air-compressing machinery. Compressed air as a motive power has so much to recommend it that it is surprising it is not taken greater advantage of in this country. In the United States, compressed air is used for mining, tunnelling, bridge building, for pumping water, operating hoists, cranes, lifts, drills, caulking tools, for stone carving, for operating petroleum oil burners, for inflating cycle tyres, and a score of other purposes. The Clayton Company manufacture plant for all these special purposes, including car propulsion. This catalogue is really a well-written treatise on air compression, and may be studied with advantage. The prices for the various descriptions of plant appear to us to be very reasonable and compare favourably with English lists.

PROCEEDINGS OF SOCIETIES.

The Transmission of Power.*

The section of the subject of the transmission of power upon which I have been requested to address a few remarks to the Section is one with which I find it extremely difficult to deal. All other methods of transmitting power than by electricity and water is an extremely large subject which it is really impossible to handle in ten minutes. Further, it is a subject which is very old and trite, and upon which it is impossible to say anything at all of an original character. In fact I may say that to Messrs. Preece and Ellington have been allotted in this matter the cream, and to me has been allotted the skim milk. That being so, even though the time during which I shall have to occupy you is so short, I shall venture to touch upon their subjects as well as mine; in fact to improve the quality of my skim milk by stealing a little of their cream.

The methods of transmitting power which are well known to all of us other than by electricity and water power appear to be those of ordinary gearing and shafting, of transmission by ropes, and of transmission by compressed air or by steam. Consider for a moment the broad characteristics of these five modes of transmission. The losses of energy in four of them are, in fact, very similar, and closely analogous to the ordinary well-known losses by friction. This is obviously the case in water-power transmission, in transmission by gearing, in transmission by ropes, and it is, I think, also the case in transmission by electricity, for the loss by electrical resistance is closely analogous to the loss by frictional resistance; and in the transmission of power by electricity the main source of loss is really by resistance. On the other hand, the losses in the case of transmission by compressed air belong to a totally different class. When the air is compressed it is inevitably heated, and when it expands, doing work at the receiving end of the system, it is inevitably cooled. The heat of the compressed air cannot practically be retained, but it is lost by conduction through the containing chamber and through the pipes which convey it. Again, in expansion the heat of surrounding bodies cannot be kept out of the cool air, and hence results a loss of power which is not analogous to a frictional loss. The methods of diminishing these losses are totally distinct in kind from those which would be adopted in the other four methods of transmission. We must look for them in the direction of avoiding as far as possible the conduction of heat to and from the working material through surrounding bodies, or in some system of regeneration having the same end in view, viz., avoiding the equalisation of temperature by conduction. This peculiarity of transmission of power by compressed air, although it involves very serious losses when applied in unsuitable cases, possesses also particular advantages for particular purposes. I refer to such work as that of tunnelling in such situations as the St. Gothard, the Vorallberg, or the tunnel about to be made on the Simplon route. Here the air which is forced into the tunnel for the purpose of propelling the drills is afterwards used for ventilation, and the fact that it is cooled in doing its work is an additional advantage in cooling the end of the tunnel. These are advantages which are absent from the other four methods of transmitting power, and render it, I think, certain that for this particular purpose compressed air is the method which will be universally employed in the future.

Comparing now the other methods of transmission one is at once struck by the great flexibility of transmission of power by electricity. The electrical conductors can, of course, be taken through all sorts of positions without trouble or inconvenience, and are very easy to repair. Further, transmission electrically can be effected at very much greater distances than can be conveniently done by any other method. It would seem that electricity must be the agent when transmission is to be made to long distances, as from where there exists a great water-power to the points at which that power can be used, and in very many cases where it is advantageous on account of its convenience. One sees electricity coming into competition with transmission by ropes or cables, both for tramways and in its use for cranes. For tramways there is no doubt that electricity has practically taken possession of the field on account of its cheapness in all cases except those where the traffic is extremely heavy or where the gradients are extremely severe, so that there are points at which there would be insufficient adhesion between the wheels and the rails. With regard to cranes, of course all of us are familiar with the type of rope-driving which was in use 20 years ago in which a high-speed rope was used for driving cranes by means of friction wheels. The far greater convenience of electric transmission will, I think, entirely supersede the rope-crane.

Comparing electrical transmission with the use of shafting and gearing, we already see that in many factories power is transmitted electrically, and a large amount of gearing is rendered unnecessary. It has there the advantage that buildings may be constructed and machinery arranged without regard to gearing and shafting. For many purposes, however, electrical transmission has a formidable competitor in transmission by water-pressure; each has its own field. It is inevitable that with electrical transmission of power high speeds of rotation must be used, and for many purposes this is inconvenient; for example, for lifts and cranes working at a slow speed. But notwithstanding the fact that there seems undoubtedly to be many places where hydraulic transmission will permanently be better suited to the purpose than electrical transmission, there can be no doubt that there are many cases in which at the present day hydraulic transmission is used which will ultimately be effected by electrical transmission of power. Consider, for example, the case of transmission upon our ships of war. Here we have at the present time, as a rule, transmission of power either by means of water-pressure or by means of steam-pressure. The consequences of the destruction of a steam-pipe by a projectile would be extremely serious; and in any case the destruction either of a steam-pipe or of a water-pipe would involve a very considerable amount of trouble in repair, whereas the breaking of the continuity of an electrical conductor would be easily and quickly made good. In conclusion, I would remark that in transmission of power electricity acts really as a mechanical gearing. As I pointed out at the outset, the losses are essentially of the same kind as frictional losses, and quite distinct from the losses in transmission either by compressed air or by steam, which depend essentially upon thermodynamic laws.

* Paper read at the Institution of Civil Engineers by John Hopkinson, Jun., M.A., D.Sc., F.R.S.

French Electric Traction.

At a recent meeting of the Société Internationale des Electricians M. Lasnier read a paper on the system of electrical traction which is used on the lines from the Madeleine to Courbevoie, Neuilly, and Levallois. This system has been in service for the last few months, and comprises three lines, one from the Madeleine to Courbevoie and Neuilly (6·7 kilometres), the second from the Madeleine to Courbevoie (6·6 kilometres), and the third from the Madeleine to Levallois. The system of traction used is by accumulators, with charging stations at the extremities of the lines; the charge is very rapid, being effected in a few minutes. The generating station contains three Babcock and Wilcox boilers, giving 1,800 kilogrammes of steam per hour at 16 kilogrammes per square centimetre, three Willans steam engines of 200 H.P. at 460 revs. a minute, each driving directly a Brown four-pole dynamo of 200 ampères and 660 volts. The distribution board is divided into three distinct parts, each part relating to one engine. Each division comprises the fusible circuit breakers, a bi-polar interrupter, a Hartmann and Braun ampèremeter, and an excitation rheostat. The feeders taken from the terminals of the board are five in number, two being used for the charging at the depôt and the lighting, and three for the lines at the termini. The charging stations are at the extremities of the lines, of which we have already spoken. The first two have a section of 150 square millimetres, and the third a section of 250 square millimetres. At the starting point of each line on the distribution board are a lever interrupter and an automatic interrupter serving as disconnectors, and also circuit breakers and an ampèremeter. At the various charging stations is a terminal which includes a board containing a circuit breaker, an interrupter, and an apparatus giving notice of the end of the charge. At the moment it stops, the driver has only to put the wires of the car into communication with the wires of the charging station and to wait for the bell to ring. The end of the charge is then announced.

The cars are very comfortable. They seat 52 persons. The Tudor accumulators, 200 in number, weighing altogether 3,600 kilogrammes, are placed under the seats. The cars themselves were constructed by the firm of David and Desouches. The electro-motors are two in number, of 25 H.P. each, and have four poles with carbon brushes. A special controlling apparatus enables all the necessary operations to be effected for starting or stopping the car. On each car are little ventilators for letting out the gases given off by the accumulators. The results obtained have up to the present been very satisfactory, the maintenance of the accumulators has been almost nil, the cars have made journeys of 6,000 kilometres. The expenditure has been estimated at 860 watt hours per car-kilometre, and at 2,591 kilogrammes of coal per car-kilometre. The electrical efficiency of the accumulators amounted to 71 per cent.

This was followed by a paper by M. E. Hospitalier on electric motor-cars. First he reminded his hearers that in 1881 he expressed the opinion that accumulators would be improved, and would be rendered suitable for electric cabs. This prediction is already partly fulfilled, and it is probable that in a year's time electric cabs will be running. He then discussed the powers attributed to the horse. This power is variable; it may, however, be estimated that a horse can produce 500 watts and 3 kilowatt hours per day. If this power and this energy is expressed by weight, we get only one watt per kilogramme and six watt hours per kilogramme. These figures are certainly below those given by an accumulator. In the case of the horse, the rein is sufficient for its guidance, it can produce at each pull a traction effort of 100 kilogrammes. Its speed is very variable.

As regards electric motor-cars we can only depend upon accumulators with a motor and controlling apparatus. These cars are supplied with all the modern improvements—the jointed axle, ball bearings, and the pneumatic tyre. With regard to the latter point, M. Hospitalier referred to M. Michelin's recent experiments and showed the advantages of the pneumatic tyre.

Accumulators have now made great progress. In 1881, we reckoned ·6 watt per kilogramme; a few years later we obtained 2 watts per kilogramme and 12 watt hours per kilogramme. In 1897 the Fulmen accumulators furnish 30 watt hours at the output of 1·5 watt per kilogramme, 25 watt hours at the output of 5 watts per kilogramme, and 20 watt hours at the output of 10 watts per kilogramme. As regards the duration of accumulators, special experiments would have to be made. But briefly, we may say that in 1881 1,000 kilogrammes of accumulators were required to produce 1 kilowatt, and 100 kilogrammes to produce 1 kilowatt hour; in 1897, 200 kilogrammes are required to produce 1 kilowatt, and 50 kilogrammes to produce 1 kilowatt hour.

Electromotors have also made very great progress. In 1881 their efficiency was barely 60 per cent., and their weight from 30 to 40 kilogrammes per kilowatt. In 1897 the efficiency amounts to 80 per cent., and their weight is reduced to 15 or 20 kilogrammes per kilowatt. Electromotors have the great advantage of supplying automatically a couple which increases as the speed diminishes; they are self-regulating. This is not the case with the petroleum motors, which produce a constant motive couple. The principal advantages of electric motor-cars are the following:—Safety, absence of jerking and shaking, stoppage of mechanism during stoppages of the vehicle, absence of heat, absence of smell, cleanliness, simplicity of construction, facility in starting and stopping. All the modern cars at the present day present almost equivalent advantages as regards elegance, economy, and inexpensiveness.

The inconveniences attached to electric motor-cars are as follows:—A charging station is required for the accumulators, the weight of the motor and the accumulator is considerable; in an ordinary vehicle, however, we must take into account the weight of the horse, which is no little. The cost is rather high. Objections are also raised against electric motor-cars on the ground that acid is used, but this liquid is placed in closed accumulators.

As regards the re-charging of the electric batteries, there are three solutions of the problem:—(1) Rapid charging at the station; (2) the replacement of the batteries after discharge; (3) charging during the night.

Rapid charging at the station would be somewhat difficult, especially if there were many cars. The replacement of the batteries would offer certain difficulties. It seems, therefore, that charging during the night would be the best way of meeting the case; 44 to 45 elements would be required, which would be charged from the distribution lines at 110 to 1,120 volts. The charging would be almost automatic; ·4 francs the kilowatt hour would probably be the price asked by the electrical companies. Lastly, various other systems have been proposed for electric motor-cars. Amongst the principal we may mention a proposal to place the whole of the Hellmann system on a car and the employment of a petroleum engine of low power driving a dynamo for keeping the accumulators charged. Lastly, portable kilowatt hours can also be used. Boxes giving car kilowatt hours could be bought. M. E. Hospitalier then briefly reviewed the chief systems of car that have been constructed. In 1881 M. Trouvé constructed an electric tricycle; various cars were brought out by Mr. Ayrton in 1882, by Mr. Magnus Volk in 1887 and 1888, by M. Carli in 1893, by M. Bouchain d'Armentières and by M. Jeantaud in 1894. In 1894 and 1895 various experiments were made in America by MM. Morris and Salom. In 1897 M. Krieger constructed a car that has already been described. To these various types we may add the Riker car of New York, Darracq's electric hansom, the Ward omnibus of London, &c.

It may be asked, What is the energy required for starting? Messrs. Morris and Salom have made several experiments with regard to this point. They found that a car weighing 900 kilogrammes, to seat two persons, would expend 83 watt hours per kilometre ton at a speed of 8 kilometres per hour, 84 watt hours per kilometre ton at a speed of 19 kilometres per hour, and 95 watt hours per kilometre ton at a speed of 32 kilometres per hour. We must, therefore, reckon about 100 watt hours per kilometre ton. A car weighing one ton will contain 400 kilogrammes of accumulators; we can, therefore, obtain runs of 60 kilometres. This would be a very satisfactory length for a journey.

The cost of charging would be about 3 francs to 4 francs per charge. In fact, in the above case for eight available kilowatt hours, the cost of the charge must be estimated at 10 francs. For maintenance and the sinking fund we must reckon 3 francs a day, or about 1,000 francs a year. Altogether, therefore, we must estimate that 60 kilometres a day would cost from 7 francs to 8 francs a day. To make a fair comparison, we must take into account such items as forage, diseases of horses, stabling expenses, &c. In conclusion, M. E. Hospitalier said that electric cars and cabs are on the eve of taking up an important position in practical traction. He hoped that Paris would cease to be an inferno of horses, and would become as soon as possible a paradise of accumobiles.

Working Tramways by Alternating Currents.—At the British Association meeting at Toronto, Professor J. Perry gave a description of an interesting method of working street tramways by alternating currents devised by himself. Between the two rails of the tramway line are placed a series of pieces of sheet iron of channel section. Each piece is placed vertically in the roadway, its plane being at right angles to the line of rails. The pieces are placed near together, magnetically insulated, forming an iron channel along the whole length of the line. The upper surfaces of the pieces are in the road surface. A flat slip conductor is laid along the channel thus formed and the whole filled in with cement. When an alternating current is passed through the conductor the pieces of sheet iron become magnetised, but in a continually changing direction. The car carries an armature, wound with a coil, having projecting pole-pieces presented to the alternating electro-magnet in the bed of the roadway. The current induced in the coil is employed to drive the motors. No illustrations were given of this apparatus beyond a rough sketch on the blackboard, but it was explained that the arrangement has been satisfactorily tested on the full-size scale on a very short line. The cost of constructing such a line had been estimated, and was calculated to be much below the cost of a conduit line.

End of the Irish Motor and Cycle Company (Limited).—An extraordinary general meeting of the Motor Cycle Company of Ireland was held on the 9th inst. at the offices, Leinster Street, Dublin. Alderman Meade, who presided, proposed a motion, which was seconded by Mr. Malcolm Inglis, confirming the resolution passed at the meeting of August 23rd, which authorised the voluntary winding up of the Company. The resolution was unanimously passed.

A BELGIAN ELECTRIC CARRIAGE.

L'Electrique (Société Anonyme) of Brussels has for some time past been studying the question of electric traction, and has designed and built the car of which we give an illustration. As will be seen, the vehicle can seat four persons. The battery is placed under the seats, and consists of 48 cells, the plates being of the Planté type. The total weight of the battery is 950 lbs., and it is charged by a current of 25 ampères at 110 volts, the time occupied being about 3½ hours. The capacity i about 86 ampère hours at a discharge of 18 ampères. The current actuates a series-wound motor, which runs at 1,750 revs. and weighs 275 lbs. At each end of the armature spindle is a pinion which, by means of a chain, transmits motion to the rear wheels. The ordinary differential gearing is, of course, being interposed. The total weight of the car, with motor and battery, is 2,420 lbs., and it can be driven, at the rate of 10 miles, a distance of between 40 and 50 miles without recharging. It will be seen that the performance is very good.

A Belgian Motor-Carriage.

Gas-Engine for Traction Purposes.—Gas engines are steadily coming more to the front in America. One is described in the *Street Railway Review* that is driving the power plant of the Traction Company of Lancaster, Ohio. This Company works from three to five cars over four miles of line with some 8 per cent. grades. The engine was put in about a year ago; it is known as the American Kilmarnock, being a single cylinder double-acting engine, and it develops 130 I.H.P., or 110 B.H.P., its rated size being 100 H.P. The speed is 180 per minute, and it drives an 80 kw. Thomson-Houston 6-pole generator. The following are the leading dimensions:—Cylinder, 16 inches diameter; stroke, 20 inches; piston rod, 3 inches; shaft, 7 inches. Two 8 feet fly-wheels with 16 face for belts. Overall length, 15 feet 11 inches; width, 6 feet 10½ inches. The total weight is 34,000 lbs. of which the wheels make up 13,500 lbs. It is to be noted that the bearings are of phosphor bronze without babbit. The engine has the porcelain ignition tube, and natural gas under high pressure is used. The load diagram shows great and sudden variations, and varies from 0 to 180 ampères. The gas consumed is 16 feet per B.H.P.

SELF-PROPELLED TRAFFIC ASSOCIATION.

LIVERPOOL AND DISTRICT CENTRE.

AT a Council Meeting of the above Association held on the 31st ult. it was resolved not to arrange an Exhibition in 1898 as originally contemplated, but it was determined to hold trials for heavy vehicles similar to "Les Poids Lourds" about May or June next year. A strong sub-committee was appointed to frame the conditions, including Messrs. Alfred Holt, M.I.C.E., Alfred L. Jones, J.P., John A. Brody, A.M.I.C.E., M.I.M.E., Everard R. Calthorp, C.E., Henry H. West, M.I.C.E., M.I.N.A., and E. Shrapnell Smith (Honorary Secretary). We hope to give full particulars in our next issue of the conditions of these important trials.

WE are glad to announce that the Second Session of the Liverpool Branch of the Self-Propelled Traffic Association will be opened early in November, when an Address will be given on the subject of "Self-Propelled Vehicles, 1896-1897," by Mr. W. Worby Beaumont, M.I.C.E., M.I.M.E.

Report of Paris Deputation on the Heavy Motor Vehicle Trials at Versailles, and on the Serpollet Tramway System (Paris).

The deputation was appointed on July 13th, 1897, under the following resolution :—"That a deputation of the Council be appointed to attend the trials of heavy motor vehicles at Paris, and to report generally upon the position on the Continent, with a view to advising the Council as to the conduct of the proposed Exhibition."

The report of the deputation, dated September 15th, commences with the trials, gives the duration of the trials, and general details of the conditions, the list and particulars of entries, the performance of the vehicles during the trials, &c., all of which has already appeared in the columns of the AUTOMOTOR. The conclusions arrived at by the Committee are then recorded as follows :—

De Dion and Bouton's System.

On Thursday, August 5th, shortly after 11 a.m., we were accorded seats in the De Dion and Bouton Omnibus (No. 14), for the run over Route A. Twenty persons were on board, inclusive of the driver and stoker. The 25·5 miles of this course were accomplished in 3 hours 22 minutes, inclusive of stoppages, or at an average speed of 7·6 miles per hour. The journey was completed without any *contretemps* more serious than a brief stoppage to tighten a joint of one of the feed-pipes. The rest of the course was accomplished with due observance of the stipulated halts, and without any special incident.

A noticeable feature in the running was the practical uniformity of speed, whether up-hill or down.

In this vehicle the motive power is steam, provided by a De Dion boiler carried on the front platform. The boiler consists of an outer double shell, containing an annular water-space, with a similar internal double shell containing another annular water-space; the two water-spaces being connected by radiating tubes. The firing is effected from the top, through the internal shell of the inner section of the boiler. It appeared to be a good practical boiler and, considering its small capacity for water, the feed-service was kept well under control. The feed-water tanks hold about 100 gallons.

A horizontal compound engine is used, and provision is made for the admission of high-pressure steam to the low-pressure cylinder, for hill-climbing and emergencies. The gearing consists of spur wheels, two ratios, which may be applied as the work to be done requires, being provided. The rear road-wheels run loose on the axle, each being driven by means of four steel arms which extend from the axle and are secured to four of the spokes at points about mid way between the boss and the rim of the wheel.

The consumption of coke and water was:—

Coke	7·6 lbs. per mile.
Water	4·4 gals.

The tare of the omnibus is 4 tons.

On the road we were able, for a short time, to observe the working of No. 13—a De Dion tractor, hauling a large covered char-a-banc for 40 persons, running on two wheels at the rear, and coupled to the tractor with a lynch-pin and locking. This tractor is fitted with mechanism and boiler similar to No. 14, of which the engines are designed to give 35 H.P. at 600 revs. per minute.

Although De Dion's have not yet built a goods motor-wagon, they claim that their tractor is suitable for attachment to ordinary wagons.

The De Dion and Bouton system, whilst exceedingly ingenious, is, in our opinion, open to the practical objection that it would require a skilled attendant and an assistant for each motor. The attention of the driver is so much absorbed with the control of the machine that, unless he had another man with him on the look-out and to sound the alarm-signal, especially in crowded thoroughfares, we think it would be difficult to secure safe driving.

	£
Price of tractor (No. 13)	580 at works, Paris.
Price of omnibus (No. 14)	880 ,, ,,

Scotte's System.

The vehicle which had the heaviest load was Scotte's "train demarchandizes (No. 2). It was said to be drawing a net load of 5 tons 9 cwt.—40 cwt. on the motor-wagon and 69 cwt. on the trail-wagon—and appeared to be a practical machine, both in its design and in its behaviour on the road. The tare of the motor-wagon is 3 tons 6 cwt., and of the trail-wagon, 1 ton 15 cwt.

"Scotte's" system may be briefly described as follows:—The front part of the motor-wagon carries water-tanks, coke-bunkers, and boiler. The boiler, which is a modified "Field," works at pressure of about 150 lbs to the square inch. The engine is of the vertical, two-cylinder type. The power is transmitted from the crank-shaft to the counter-shaft by means of sprocket-wheels and chain gearing; this second motion shaft carries the compensating gear and sprocket-wheels for driving the rear road wheels by means of pitch chains.

The three Scotte vehicles (Nos. 1, 2, and 3) ran throughout the trials with good results and remarkable regularity, but the remarks as to the necessity for a skilled attendant and an assistant apply to this system as much as to that of De Dion and Bouton.

Omnibus No. 1 returned the following consumption over Course C:—

Coke	13·0 lbs. per mile.
Water	9·8 gals. ,,

	£
Price of motor-wagon (No. 2)	880 at works, Paris.
,, trail-wagon	600 ,, ,,

For more than six months a regular daily service of their omnibuses has been conducted between Courbevoie and Colombes in the suburbs of Paris, with satisfactory results. The distance between these places is almost three miles. The fares are 4½d. first class, and 3d. second class. Two omnibuses (similar to No. 3) work the route, one plying each way every three quarters of an hour. The owners of these vehicles state that, compared with horse omnibuses, a very considerable economy has been realised.

Scotte's Company—La Société des Chandières et Voitures à Vapeur, 56, Rue de Provence, Paris—has already turned out a considerable number of motor-wagons (with and without trail-wagons) which are running in the Meuse and elsewhere. We were informed that road-traction companies have been formed for establishing services on this system at Lyons, in the Ardèche, Rhône, and Côte d'Or, in which districts the traffic is insufficient to admit of the expenditure involved in laying down rails for tramcars. The distances between the points to be served vary from three to 16 miles.

M. Scotte furnished us with the following working costs:—

Length of route, 6½ miles.
Motor-car and trail-car carrying 38 passengers.
Two machines, each making four double trips per day.

	£
CAPITAL OUTLAY—	
Three road-trains (one in reserve)	3,120
Depôt	200
Total	£3,320

ANNUAL WORKING EXPENSES—			£
Depreciation at 10 per cent.			332
Interest at 5 per cent.			166
Total			498
		£	
600 kilos. coke per day at 3 francs		263	
Oil and grease		58	
Two drivers at 4*s*. 9*d*. per day		175	
Two stokers at 4*s*. per day		146	
One attendant at depôt		73	
Repairs and sundries		234	
			949
Total			£1,447
Cost per car-mile			9·5*d*.

All the machines exhibited very great ingenuity of design and construction, one of the most interesting being Panhard and Levassor's Omnibus (No. 10). This vehicle is fitted with a four-cylinder vertical oil-engine carried in front under the box seat. The crank and counter-shafts are longitudinal with four sets of spur-wheels for variable speed, motion being imparted by a bevel-wheel to a transverse shaft which carries the compensating gear and sprocket-wheels for driving the rear road wheels by link chains. This vehicle consumes only about $1\frac{1}{2}$ pints of petroleum spirit (0·680 S.G.) per mile but, in common with all oil-motored carriages, has the serious disadvantage of very considerable vibration when standing or running at a low rate of speed.

Before leaving Versailles, on August 6th, arrangements were made with Mr. Arthur Hopkins and M. Serpollet to inspect the Serpollet tramway system on the following day (Saturday), and Count de Dion extended an invitation to us to visit his works at Puteaux.

Serpollet's Instantaneous Steam System.

The report gives a very full description of the details of this system, mostly taken from the pamphlet issued by M. Serpollet, of which particulars have some time since appeared in the pages of this journal. In regard to driving the tramcar the report continues :—

Four appliances only have to be attended to by the driver, so that his attention may be devoted largely to the road, and to his action dependent upon the obstacles, if any, in his path :—

1. The hand-pump for starting.
2. The pass-valve or balance-valve for regulating the speed.
3. The reversing lever.
4. The brakes.

M. Serpollet is then quoted as follows :—"When it is necessary to leave the depôt, the driver, having shut the pass-valve, gives a few strokes to the hand-pump, and in half a minute sufficient pressure is obtained to start the car. After this the necessary variations of speed are obtained solely by manipulating the pass-valve, opening it to reduce speed, and *vice versâ*. For ordinary stops it is not necessary to work the hand-pump at all, for, after putting his foot upon the pedal brake, the driver moves over the reversing lever to the mid position. In this position of the gear, the ports of the cylinder being closed, although no more feed-water is being supplied, the boiler remains under pressure for a few minutes. Under these circumstances, in order to start the car again, the driver has only to take his foot off the brake pedal, and to place the reversing lever in the forward position."

The advantages of the modifications now being introduced are at once manifest. Before starting, the balance-valve is adjusted to a pressure of, say, 100 lbs. per square inch, such pressure being constantly maintained even during a protracted stoppage. The steam being cut off from the engines, there is no necessity to place the reversing gear in the mid position. The facility with which these tramcars stop, start, slacken speed, and climb moderate gradients is remarkable.

In Paris, an ordinary driver is entrusted with a Serpollet car after a week's teaching by one of his mates.

Weight of 50-seated motor-car (with water and fuel)	10 tons.
" " trail-car	$3\frac{1}{2}$ "
Minimum radius of curves on Paris lines	83 ft.
Wheel base of cars	6 ft. 4 in.
Diameter of car wheels	2 ft. 8 in.

There are now 60 of these cars working in Paris, and 40 more are to be added within the next few months, when the 100 cars will replace 1,500 horses, and provide a more satisfactory service in many respects. We understand that about 500 additional cars are to be built as quickly as possible.

M. Serpollet informed us that an experimental oil-fired car (créosote brute) had just been completed for La Compagnie Générale des Omnibus de Paris, and that its trials had given every indication of success. It is expected that this car will begin to run in Paris about the end of the present month.

Advantages.

We consider that the Serpollet system is at present the only steam system that can be entrusted to the care of an unskilled driver. The boiler is practically inexplosible.

No gauge-glasses, safety-valve, boiler-mountings, or pressure-gauges are required.

As a matter of fact, pressure-gauges are used but only for the secondary purpose of seeing what power, roughly speaking, is being exerted.

It is never necessary to blow off steam.

The steam pressure can be rapidly varied from zero to a maximum, which "flexibility" of power is a great desideratum in tramcar propulsion.

The steam is provided in a highly superheated state and also discharged as a practically invisible vapour with the hot fire gases.

No appreciable noise arises from the exhaust.

Possible Disadvantages.

TUBES BURNING OUT.—Experience appears to have shown that the only risk is with the bottom row which is nearest to the fire. The "life" of these lower tubes depends very largely upon the careful attention of the driver when the car stops at each end of the route. By closing the ashpit door, so little air is admitted that the fuel is burnt only to carbon monoxide (CO), and this, being a reducing gas, does not burn the iron tubes which in the bottom row may last 12 to 18 months and the others some years.

INCRUSTATION.—This seems to be much less than might have been anticipated. The reverse scouring action of the steam when the pass-valve is opened for a stoppage appears to carry back into the feed-tank much of the deposit. In practice the tubes are cleaned by forcing through them a couple of gallons of kerosene once a fortnight.

The largest deposit is in the tubes through which the feed-water first passes. These lower tubes, however, are of a different section to the others, there being a narrow annular space for the water to pass through, and their ends are specially constructed in such a way as to permit of their being easily cleaned out.

LOW EVAPORATIVE POWER OF BOILER.—Where fuel and water cannot be obtained at comparatively short intervals, this might be a source of trouble by reason of excessive storage being required on board, but in the case of a tram-service this objection would not signify.

It must not be overlooked that, although the actual evaporation is only 6 lbs. of water per 1 lb. of coke, the steam is highly superheated. The evaporation is probably equal to about 10 lbs. of water per 1 lb. of coke from an ordinary tubular boiler.

THE SERPOLLET CARRIAGES are fitted with similar arrangements on a reduced scale. We examined some in course of construction and noted that their boilers are oil fired. Two oil-tanks are provided: one as a reservoir, the other for air-compression and delivery of the oil. In one carriage the latter has a capacity of three gallons; two gallons of oil are pumped into it by hand from the reservoir, and so pressure is obtained to feed the burner. This consists of a spiral terminating in a tube fitted with five jets and bye-passes. A cupful of methylated spirit is required to start vaporisation, which is maintained by the burning oil. Ordinary kerosene (about 0·800 S.G.) is used.

The introduction of oil fuel has permitted a considerable reduction to be effected in the thickness of the tubes, on account of the readiness with which the supply of heat can be regulated.

The two-seated three-wheeled carriage weighs 10 cwt., inclusive of $5\frac{1}{2}$ gallons of kerosene (enough for a run of 90-95 miles), and 16 gallons of water (enough for a run of about 40 miles). The four-seated four-wheeled carriage weighs 18 cwt. inclusive of fuel and water. Unfortunately, we did not see these carriages working, but learnt independently that the experimental vehicles already tried have given satisfaction.

We append the working costs per car-mile of Serpollet's 50-seated during the year 1895, as divided by La Compagnie des tramways de Paris et du département de la Seine :—

Production of steam (coke and bonus to driver)	2·67*d*.
Running expenses (driver, conductor, lubrication, &c.)...	1·59*d*.
Maintenance of cars, engines, and boiler	2·09*d*.
Total	6·35*d*.

It will be remarked that the first item is excessive, but M. Serpollet pointed out to us that they then had no data to guide them in economical firing or advantageous disposition of the elements; a liberal supply of fuel was given to each driver, with the offer of a considerable premium for low consumption. On a straight run, the cars use now only 4 to 4·5 lbs. of coke per mile, the average for a daily mileage of 75 miles being about 7 lbs. per mile throughout the day, inclusive of consumption while standing at termini.

After several years' experience, the cost of working has been considerably reduced, and M. Serpollet furnished us with the following details as representing the present cost per car-mile of a 50-seated car :—

Coke—7 lbs. at 32*s*. 6*d*. per ton	1·24*d*.
Running expenses (driver, conductor, lubrication, &c.)	1·59*d*.
Maintenance of cars, engines, and boiler	1·61*d*.
Total	4·44*d*.

When correction has been made for reduced expenditure on fuel in this country, the cost per car-mile is not more than 4*d*.

Both the above sets of costs refer to 50-seated cars hauling similar trail-cars on Sundays and Fête days.

The price of Serpollet's 50-seated motor-car varies from £1,310 to £1,420 (at works, Paris), according to the system of brakes, the nature of fittings, and other details.

Reviewing the numerous systems and vehicles that came under our notice, we are of opinion that—

1. Scotte's and De Dion's vehicles are the only ones we saw capable of dealing with loads such as we in Liverpool require to move.
2. Serpollet's system has been admirably worked out for tramcars, but, owing to the demand for these, not much has yet been achieved in its application to ordinary road vehicles.
3. Oil-engines (internal combustion), using petroleum spirit, are developed to a high degree of lightness and economy for pleasure carriages and vehicles of a small gross weight.
4. There can be no doubt as to the popular feeling in France, where the liveliest interest is evinced in all matters appertaining to automotors, but it is more from the point of view of pleasure-seekers with a novelty than of business men with work to do. At the same time, the practical carrying aspect of the question is attracting attention, and efforts are being made to produce vehicles for the transport of goods. No thoroughly satisfactory vehicle for really heavy traffic was, however, produced at these trials.
5. As our investigations show that no heavy vehicle in France has yet reached such a stage of development as to appear to be suitable for the requirements of this district, we are of opinion that the public trials which the Association proposes to hold next spring should be proceeded with, in order to ascertain the actual position of English effort to produce self-propelled vehicles for heavy traffic on common roads.

6. As now constructed, neither Scotte's nor De Dion's vehicles would be of any use in this country, owing to the tare weights being in excess of those allowed under the provisions of the Locomotives on Highways Act, 1896. These machines unquestionably have in them the elements of practical success.
7. Whilst our conclusions are not entirely favourable to the motor-wagons put forward on this occasion for the transport of heavy goods, there is no doubt that Scotte's and De Dion's systems are efficient and economical for passenger services, and that Serpollet's tramcar system is a proved success.

[This has only come to hand at the time of going to press, and hence there is not time for detailed criticism. With one remark in the report we must entirely dissent. The report says:—"No thoroughly satisfactory vehicle for really heavy traffic was, however, produced at these trials." This is simply not so. Considering the state of the roads, the performances of the De Dion and Scotte motors were remarkable, and there cannot be the slightest doubt that either of these systems, so far as reliable mechanism is concerned, is quite capable of dealing with the Liverpool and Manchester route. We regret that such (to us) erroneous estimate should have been formed.—Ed.]

Is Saul also amongst the Prophets?—In our last month's issue we had an article criticising, we admit somewhat severely, the General Post Office and its methods. We showed how high-class monthly publications, or even, for that matter, any kind of monthly paper, was severely taxed in its postage as compared with the rates levied on ordinary newspapers. That our comments should have attracted attention was, of course, only natural, especially from those who constitute the grade known as the "higher official." One does not write for the purpose of uttering vain nothings; but we certainly rubbed our eyes to find that the *Electrical Review*, of all papers, was acting as the champion of the Post Office. Says our contemporary:—"The Automotor and Horseless Vehicle Journal seems to have gone a little out of its legitimate line in writing on the above subject Like many other journals, the paper in question assumes that because nothing is said, therefore nothing is done; in other words, that because the scientific exploits of the engineering branch of the Post Office are not blazoned abroad, that therefore they do not exist. It would probably be an eye-opener to our contemporary if it were allowed to inspect the records of work done in the engineering branch of the Post Office. No doubt it is perfectly true that 'one sees but little evidence of acquaintance with the latest advances in telegraphy,' but with some people only seeing is believing. We have before pointed out that the Post Office is not a public laboratory, whose chief function is to carry on original research; it has quite enough, we expect, to do in developing and improving existing forms of apparatus, and in keeping these up to modern requirements. Those whose ideas of telegraphy consist in the notion that a telegraph is simply a wire on a number of poles, worked by a single-current key and a Morse sounder, may be excused if they think the work being done by the Post Office engineering officials is of a trivial nature; but no doubt the officials will manage to survive the contempt with which they are looked upon." In the first place we "assumed" nothing, and we are as likely to imagine vain things as the *Electrical Review* is to "assume" the medical properties of so called electric belts; secondly, we claim to have some knowledge of what the Post Office has achieved and attempted in telegraphy, and especially in submarine telegraphy, and we are glad that the *Electrical Review* agrees with us that it is perfectly true "that one sees but little evidence of acquaintance with the latest advances" in that branch of applied science. We have not said that the Post Office is a public laboratory. We know it is not; but we do know something of its experiments with the sea as the laboratory. We drew attention to certain anomalies in the postal service which even this latter champion of the G.P.O. cannot deny exist and which we submit are evidences of incompetency, and this incompetency we believe to be due to the vicious system of selection and promotion that obtains. We remember the time when the *Electrical Review* was not slow in detecting and exposing those who preyed upon the public, whether they were high officials, quack doctors, or dishonest exploiters of primary batteries; and our contemporary rendered yeoman's service in this connection. Yet, because we remonstrate with the higher officials of the Post Office about these anomalies, our contemporary pours out the vials of its wrath upon us. *Et tu, Brute!*

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "The Automotor and Horseless Vehicle Journal" by Herbert Haddan and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

*** *At the request of a number of subscribers we are pleased to announce that for the future we have arranged to more thoroughly cover the field of completed Patents referring to the Motor-Car Industry, by reproducing the latest Specifications and Diagrams.*

Specifications Published.

25,309. Rims and Tyres of Wheels. William Thomas Fitzgerald, Parkfield House, Maindy, Cardiff, Glamorgan. November 11th, 1896.

This invention relates to improvements in and relating to rims and tyres for wheels for carriages, autocars, motor-cars, and other vehicles, and has for its object the construction of a simple method, which does not consist of complicated mechanism, and has for its object the securing of sections of arched wood, leather, rubber, papier maché, composition, or any other suitable substance to act as a tyre which would grip the road, run quietly, reduce vibration and strain, and be economical in construction and repair.

The invention consists of two rims of angle iron, steel, flange, or other durable material, with half holes drilled to fit on tongues of spokes, right and left, filling between the angles of rims outwards, with sections of arched wood, leather, rubber, papier maché, composition, or other suitable material, and securing the same with bolts, or rivets, fitted in horizontally.

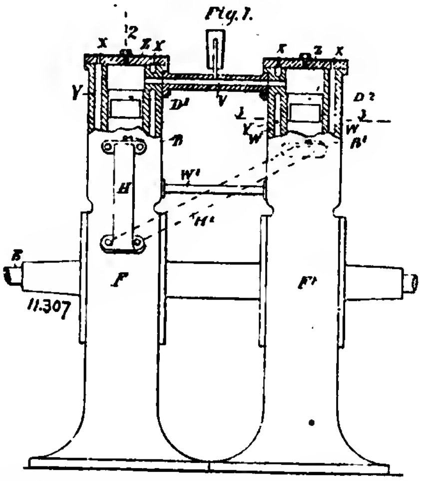
1,886. Transmitting and Regulating Motion. Charles Casman, 50, Rue de la Gaîté, Brussels, Belgium. January 23rd, 1897.

This invention relates to an apparatus for transmitting motion and for varying the speed of the motion imparted by a motor without varying the speed of motion of the said motor, and comprises a lever in which a longitudinal slot or groove is cut and to which an oscillatory movement about its axis is imparted from a motor, an endless chain passing over suitable pulleys and having its ends fixed to the ends of a rod, a triangular frame fixed at one side to the said rod and having a groove or slot parallel to one of its free sides, a cross having in its transverse bar a horizontal slot and in its vertical limbs longitudinal grooves or slots, a slide-block adapted to move at the same time in the slots of the aforesaid lever and frame, and in the said horizontal slot, two fixed pins engaging in the grooves or slots in the vertical limbs of the cross, and means for causing the cross to move up and down upon the said fixed pins.

11,307. Gas and Oil Engines. Joseph Day, Compton Villa, Paragon Road, Weston-super-Mare, Somerset. May 23rd, 1896.

The engines are constructed to work preferably with an impulse at each revolution and two or more are coupled together. The charge of air and gas or of air and oil is smaller than is usually the case, and after being compressed ignition takes place in a tube or chamber between the two cylinders, and consequently operates the pistons simultaneously. One engine is conveniently constructed to draw in and compress the air, and gas in the case of a gas-engine, or air alone in the case of an oil-engine for the purpose of charging the working cylinders, the connections between the air and gas or air and oil being suitably arranged for that purpose, so that as far as concerns the operations of charging, one engine performs double duty, the result being that increased expansion is obtained.

Fig. 1.



A further improvement consists in the method of and means for the utilisation of air instead of water to keep the cylinder or cylinders cool. The cylinders are provided with jackets and air is drawn through these jackets to be utilised eventually to form part of the charge for the engine. By this means the air is also warmed before it reaches the cylinder, which is an advantage. The air jackets may be of ordinary construction, but preferably the air should cover as large a surface of the outside of the cylinder as possible. For this reason the cylinder may be provided with a number of thin fins either vertical, helical, horizontal, or of other form.

2,595. Means for Exploding Combustible Mixtures, and Utilising the Explosive Force thereof for Driving Rotary-Engines. Maximilien Ringelmann, 47, Rue Jenner, Paris. Date Claimed, August 1st, 1896; Date of Application (in United Kingdom), February 1st, 1897.

This invention has for its object the application of explosive mixtures to the working of rotatory engines, the explosive mixture being composed of air added to combustible gas, or to a combustible vapour, or to an explosive body.

The essential principles of the invention are dispensing with compression previous to explosion, and dispensing with the use of cooling water, and the production of the "cycle" in a vessel or chamber separate from the engine.

It consists of a system of explosion generators into which an inflammable product is introduced, which, after mixing itself with the existing air is fired, and produces in the above-mentioned generators or vessels (which may be of any number) a pressure which is employed to turn a rotary engine, and thus this system dispenses with the necessity of cooling, and the explosion takes place without previous compression; and an arrangement by means of which the scavenging after each explosion is made; a fan or air pump for driving out (after each explosion) the products of combustion left in the generator and replacing them by a quantity of air sufficient for the succeeding explosion.

12,137. Horseless Carriages, and in Motors for Driving same. James Frederick Stilwell, 1, Victoria Park, Dover, Kent. June 3rd, 1896.

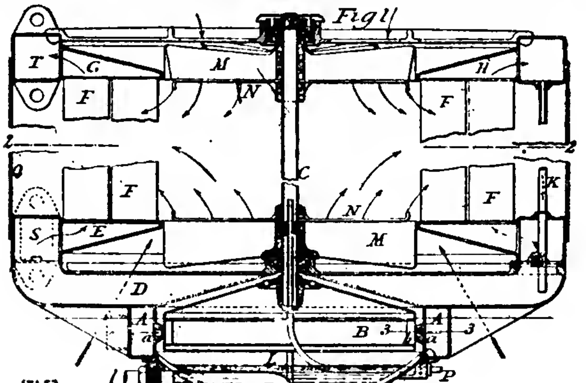
Consists in making the horseless carriage with a removable fore-carriage or bogey, which is provided with a suitable frame on which is mounted the motor in such manner that the whole fore-carriage containing the motor is capable of being easily attached to the carriage itself. The motor frame is mounted on one, two, or more wheels, one or all of which is or may be a driver or drivers. The wheels (when there are two or more) are mounted in such manner that the wheels on the same shaft shall both act as drivers, but both may revolve at different velocities when turning corners and the like.

The vertical pivot on which the motor frame turns is preferably made hollow so that the rods or handles for starting, stopping, or otherwise effecting the working of the motor all lead to or near one spot convenient to the hand of the operator. If an electric motor be used it is evident that some or all of these rods or handles may be replaced by wires and switches. The steering may be conveniently effected by a spur wheel on the hollow pivot and by a pinion mounted on a spindle, at the other end of which is a hand wheel or handle or in any other convenient manner.

13,452. Condenser for Motor Vehicles. Henry Percy Holt, No. 22, Chancery Lane, London. June 18th, 1896.

Relates to a light, compact construction of condenser for the steam or vapour used for propulsion of a motor vehicle.

The exhaust steam or vapour from the engine is supplied to an annular horizontal tube or conduit, A, from which it issues by a number of inclined nozzles, *a*, in jets, playing upon the blades, *b*, of a turbine, B, which is mounted on a vertical axis, C, concentrically within the conduit. The steam, after passing the turbine blades, flows by passage, D, into a segment, E, of another circular conduit, from which it rises through a number of flattened tubes, F, which may be corrugated as shown, or otherwise shaped to a conduit segment, G, above. From this upper segment, G, it passes into other segments on the same level at each side of G, and thence descends another set of the tubes, F,



13452.

to other conduit segments at each side of E, thus circulating in an up and down zigzag course to the last of the upper segments, H, whence the liquid of condensation passes down by pipes, K, to a central well from which it is led by a pipe, *l*, to the feed supply of the engine. On the axis, C, of the turbine there are fixed two fans or air propellers, M, M, the one on the level of the lower conduit segments, such as E, the other on the level of the upper segments, such as G.

These fans draw air into the central space and propel it in all directions outwards as indicated by the arrows between the corrugated tubes, F, cooling them so that the steam or vapour passing up and down through the tubes becomes condensed. To the fans, M, are fixed revolving pipes, N, N, each like a Barker's mill, so as to throw out fine water spray to mingle with the air currents as they pass onwards. Water for this purpose is supplied by a pipe, P, to the interior of the shaft, C, which is hollow, and with which the pipes, N, communicate.

The air, after passing the condensing tubes, is collected in the space outside the tubes, F, within the casing, and led by a conduit to mingle and pass away with the products of combustion from the boiler.

3,562. Steering Mechanism for Autocars and other Vehicles. Nicholas Vincke, 78, Rue Léopold, Malines, Belgium. February 10th, 1897.

Relates to a steering mechanism for vehicles of all kinds and more particularly or autocars.

The two front wheels of the vehicle turn upon journals formed on the outer sides of intermediate parts, which are pivoted to the axle by means of a hinge or other suitable joint or connection which allows of their movement in a vertical plane. Behind or in front of these parts there are arranged two arms, which are inclined towards each other. A bar is pivoted to the arms directly at one end, and indirectly at the other end by means of a sleeve.

To this sleeve there is jointed a rod, which is also jointed at its other end to an arm pivoted on the central part of the axle. Upon this arm there is provided a double-arched or curved spring, above which there is mounted an operating rod, around which is coiled a helical spring. The operating rod is provided with a toothed sector gearing with a pinion driven by means of a second pinion, which is mounted on the end of the shaft of the operating hand wheel.

12,157. Improvements in Road Motor-Cars. John Brown, of Longhurst, Dunmurry, near Belfast. June 3rd, 1896.

Consists in motor-cars having exterior covers for the wheels and low centre of gravity, the use of spring wheels, the axles of which are connected directly, or by means of gearing, to the prime motor and revolve in bearings rigidly.

16,716. Motor Road Vehicles. Hurbert Charles Baker, No. 30, Main Street, Hartford, Connecticut. July 28th, 1896.

Consists of the combination, with a driving and a driven shaft supported in axial alignment, of two conical friction-drums of relatively different diameters, one of which is fixed to the driving-shaft and the other of which is journaled for rotative movement on the driving and driven shafts, with its diametrically-reduced end adjacent to the diametrically-reduced end of the other drum; a differential train of gears connecting the adjacent ends of the driving and driven shafts, and embodying driven gears controlled in their movements by the rotative movement of the last-mentioned drum; two friction-rolls of relatively different diameters in peripheral engagement, respectively, with the two conical drums and one of which rolls is driven by the other through the medium of the fixed drum, and hand-operated means for shifting the friction-rolls longitudinally of said drums to increase or decrease the rotative movement of the gear-controlling drum with relation to the fixed drum and arbitrarily stop or reverse the direction of rotation of the driven shaft.

13,559. Motors for Motor Vehicles. Walter Harris Knight, New Brighton, New York, United States of America. June 19th, 1896.

The invention relates, first, to controlling mechanism for fluid-pressure motors, and, secondly, to certain improvements in details of mechanism.

A suitable engine cylinder is supported from the car, and the piston working in the cylinder is connected through the sliding cross-head and connecting-rod with the crank of the car axle. A reservoir for compressed air is also supported upon the car and communicates through a suitable passage with the fluid supply chest of the motor, in which supply chest operates the distributing valve which also operates as a cut-off valve. A suitable link mechanism for operating the distributing valve is provided, said link mechanism being operated as usual by means of the eccentrics mounted upon the crank axle. For controlling the action of the distributing and cut-off valve, the link mechanism is connected to a suitable operating crank, which is in turn connected to a controlling rod.

In the passage leading from the compressed-air reservoir to the distributing chest of the motor is provided, first, a high-pressure throttle valve, next, a reducing valve, next a low-pressure reservoir or heater, and, finally, between the heater and the motor-cylinder, a low-pressure throttle valve. The reducing valve is automatic in its operation, but the high-pressure throttle valve and the low-pressure throttle valve must be opened and closed by hand. The low-pressure throttle valve is necessary in the system to completely cut off any

MISCELLANEOUS ADVERTISEMENTS.

supply of fluid to the engine from the heater, while the high-pressure throttle valve is necessary to prevent the leaking of fluid through the reducing valve to the heater. To operate the throttle valves suitable toggle link-levers are provided, which are connected to the controlling-rod before referred to. The controlling-rod is operated by a single hand lever, whereby the two throttle valves and link mechanism can be simultaneously operated for controlling the action of the distributing and cut-off valve and the supply of fluid to the reducing-valve and motor. Modifications are described.

12,539. Fly Wheels for Motor-Cars. Arthur Paget, 2, Harcourt Buildings, Temple, London. June 8th, 1896.

For electric motors the fly wheel is constructed of a thin cylindrical shell of copper or other material adapted to be filled with water and which may either be divided into chambers or compartments or fitted with a vane or vanes so as to ensure the water partaking of the movement of the fly wheel, so that when the wheel is charged it is sufficiently heavy to serve as a fly wheel, while, on the other hand, when it is empty, the wheel adds little to the weight of the carriage.

For oil or explosion motor-cars the fly wheel is kept charged with water and serves as the reservoir from which the water for cooling the engine is obtained, the circulation of the water being maintained in any suitable manner. A convenient way is to cause the water to circulate from the fly wheel to the cylinder through the crank shaft and bearings. Holes are bored through the crank shaft communicating with the interior of the fly wheel, and suitable connections are made with the water ways in the crank shaft through the bearings fitted with stuffing boxes. However little water there may be in the wheel, such water will by centrifugal action be found at the rim, and consequently the connections should be adapted and arranged so as to collect the water at the periphery. The return pipe by which the water is collected is so arranged as not to partake of the movement of the fly wheel, being carried on a bearing at the outer side of the fly wheel fitted with a stuffing box.

10,345. Stopping Apparatus for Motor-driven and other Road Carriages. Walter Woolidge, Strand, Southampton. May 14th, 1896.

Relates to a stopping apparatus or mechanism for road carriages or road motor-carriages, consisting of one or more projections or recesses formed on or in or attached to one or more of the wheels of the vehicle or some revolving part contiguous thereto; of a shape suitable to impart a reciprocating motion to a pump, rod, or lever engaging therewith; a brake or brakes operated thereby; a lever or rod, or levers or rods, operated by the said projections or recesses for forcing the brake into action, and provided with non-return checks or clutches, means for releasing said clutches by manual power, arranged so that unless held out of action by the person in charge, the vehicle is certain to be stopped after travelling the distance to which it may be set, and means for setting to stop at any desired distance.

11,506. Railway and Road Vehicles Driven by Oil Motors. John Magee, 38, Pembroke Street, Glasgow. May 27th, 1896.

The motor is so constructed that the cranks revolve in a closed chamber. The motor is geared to the driving axle of the vehicle by means of ropes or belts, or by means of chains and pulleys. The brake for road vehicles consists of two bars or brushes, one at each side of the vehicle, which are brought into contact with the road. The wheels of the vehicle are so constructed that the spokes act as springs. This is accomplished by bending or coiling the spokes in a peculiar manner so as to give sufficient strength and at the same time considerable elasticity. An alarm whistle may be provided which is actuated by the burnt gases from the motor.

To enable the vehicle to turn in a small space, any of the wheels can be allowed to run loose on the axles. The brakes can be operated by means of the exhaust gases acting on a piston or diaphragm connected with the brakes. The vehicle can be reversed by simply reversing the engine, or by means of the chain, rope or belt gearing, the engine running in one direction only.

To keep the cylinders cool a small tank is employed with water in it; also a pump to force or exhaust air from the jackets of the cylinders. The exhaust gases may also be employed to assist in cooling the cylinders. A pump exhausts the air from the cylinder jacket, then a small jet of the exhaust gases at a high pressure is projected into the jacket, a partial vacuum being in the jacket the sudden expansion of the exhaust gases lowers the temperature. The exhaust gases can also be utilised to give a constant feed of oil to the motor by being allowed to act on the surface of the oil and subject it to compression, or to act on a piston or pump for forcing the oil.

12,109. Carburetting Apparatus. Prosper Hérens, 113, Rue Royale, Brussels, Belgium. June 3rd, 1896.

The object is an apparatus for the carburetting of hydrogen, produced by the process of chemical decomposition of water by means of the reaction of an acid on a metal, or by any other process, as well as for the carburation of common coal or illuminating gas.

The reservoir, which may be cylindrical or of any other suitable form, is made of copper, iron, aluminium, lead, or other metal, and may be covered outside with cement. It is surmounted by a lid, fastened by means of bolts and winged screws to the collar of the reservoir. This lid is furnished with a tubulure, having a screw-threaded capsule for the introduction of the liquid, with a tubulure having a tap as an outlet for the carburetted gas, and with an opening for the introduction of a pipe for the passage of the gas, it being also provided with a tap. This pipe plunges to near the bottom of the reservoir and is terminated by a recipient which may be cylindrical or of any other suitable form, perforated in all its walls.

The reservoir is provided laterally with a level-indicator, and, in its lower part, with a discharge-tap to regulate the level of the carburetting body.

KELVIN'S LAW OF ECONOMY.

It is within the common experience of all who purchase and operate plant of any description that some machines are dear as regards first cost, but cheap to run and maintain, while others are cheap in the first instance but very expensive to work. This is such a truism that instances will occur to everyone, from the manufacturers of the ocean steamship to the housewife who uses a patent mangle. In purchasing plant our object is to associate small first cost and small working cost, but rarely is this attained. Now it is evident that between a high prime cost with small working cost on the one hand, and low prime cost and high working cost on the other, there must be some particular prime cost at which the annual working expenses, together with the interest on the prime cost, must be a minimum. What this cost is can be determined by the aid of Kelvin's Law of Economy. Briefly, this law states that *the most economical design in any case is that in which the annual interest on the cost of an increment of material is equal to the saving in annual expenses which results from that increment* This law has the widest possible application, but is hardly known outside the higher engineering circles, yet it is one that the manufacturer, the tradesman, and the housewife might with advantage study; as has been very truly said by a well-known engineer, "it is eminently a shareholders' law"; and were it better understood many mistakes in business would be avoided. Although known as Kelvin's law, yet it was first enunciated by the great French mathematician, Fourier. By the application of this law the manufacturer can say with certainty whether it would pay to put down any given piece of mechanism. It determines the most suitable piston speed of an engine, and the most suitable boiler pressure; it also determines the most suitable speed, and therefore weight of machinery of steamships. It enables a butcher to say definitely whether it will be more economical to use a gas-engine or an electromotor to cut up his sausage meat. It likewise enables the city clerk to determine at what distance he must live from his office in order that his rent and travelling expenses may be a minimum. In applying the law it must, however, be clearly understood that it involves stated conditions only; there may be other circumstances which may render a departure desirable; for instance, we might determine that a steam motor was the most economical for a given purpose, but if our next door neighbour carried on a business involving the use of naphtha or other volatile or inflammable substances, the County Council and the fire insurance companies would very properly interfere. Such circumstances do not, however, invalidate the law, which is rigorously true within its own limits. It is because this law is so little known that we see so much tentative experiment going on around us. Thus Regent Street is being paved with Jarrah wood; Fleet Street with pine. Both kinds cannot possibly be the most economical, and the ratepayers' money is unquestionably being wasted by one or the other of the authorities concerned. Similarly the Chiswick Local Board is, we are told, bumptiously "experimenting" (*sic*) with a Thornycroft dust collector. Really there is no "experiment" needed. Kelvin's law enables us to say definitely what, if any, the economy will be, only it is more than probable that the Chiswick Board knows nothing of the law. Similarly we are told that Shoreditch is also making an "experiment" in obtaining power from burning the voluminous refuse of that dirty and dingy district, and when members of other vestries are asked why they do not go and do likewise they assume a profoundly ludicrous air of superior wisdom and tell you that "they are watching the experience at Shoreditch"! When really the reason is that they never heard of Kelvin's Law of Economy.

A 2

One more example. We Londoners are as regards street traction hopelessly behind many third-rate provincial and continental towns. We tenaciously adhere to the obsolete, costly, inefficient, filthy system of horse traction, and were it not for the aid of an army of sweepers the street would reek, as indeed they often do, with horse-filth. Why is not mechanical traction of some sort adopted for trams and omnibuses? Simply because those who manage these things know nothing of Kelvin's Law of Economy, and so the long-suffering and patient public incurs needless inconvenience and expense through the ignorance of tram and omnibus directors.

What deters many people from mechanical traction, who would otherwise employ it, is the difficulty of ascertaining whether the change "will pay." Kelvin's Law of Economy enables us to say definitely for any given set of conditions to which it is applicable, whether it will or will not pay to employ a mechanically-propelled road carriage. As this question is frequently addressed to us, and as a correspondent has asked our advice, we will give the application of this law.

We will consider the case of a tradesman in good circumstances who, as our correspondent, for purely business purposes, and for no love or interest in horseless traction, finds it necessary to add to his stock of conveyances. We assume, as a basis of calculation, that an average horse and van costs £90, and that a 3½ B.H.P. heavy oil motor-van of the same capacity costs £220, that the working year consists of 313 days of 10 hours each, and that the annual charges of working are as follows:—

Horse and Van.

	£
Carman's wages at 25*s*.	65
Depreciation at 10 % on £90	9
Horse food, straw, &c.	30
Rent of stable, gas, water, implements, and utensils	15
Veterinary and farrier	1
Cost of working per year	120

Motor Van.

	£
Driver's wages at 25*s*.	65·00
Depreciation and repairs at 10 %	22·00
Petroleum at ·5*d*. per pint per B.H.P. per hour	22·82
Lubricating oil, waste, &c.	5·00
Total cost of working motor-van per year	114·82
" " horse and van per year	120·00
Saving in annual expenses by adopting motor-van	5·18

Now, the difference in the prime cost is £130; that is, the motor-van costs more by this amount, but, according to the law, economy will be effected when the interest on this equals the saving in annual expenses. Now, £5·18 is the interest at 4 per cent. on £130. Hence, in this particular case it would be distinct economy to employ a motor-van. As a matter of fact, the figures we have given are capable of much modification. As regards the horse and van expenses, they represent fairly enough the charges that are incurred by a tradesman in an expensive neighbourhood. They, of course, are not applicable to a coal hawker, for instance, who is his own carman, and whose expenses for fodder, stable rent, &c., are perhaps not more than 15*s*. or 20*s*. per week. Also these figures are no indication of the cost of working a horse and van in the country, where pasture and stable-rent are merely nominal items. Clearly in these cases there might be no saving in annual expenses, and hence the motor-van is so far only economical in the wealthy shopping districts of London and other large cities, where rents are high.

Let us now take another business case. A country doctor has a horse and gig or other conveyance, which he can sell for, say, £100. Will it pay to replace this by a motor-dogcart of 3½ B.H.P., and costing, say, £250 prime cost? Now, in a country town the expense of a horse and gig will certainly be not less than £100 per year, and the expense attending a motor-car on the basis of six hours per day for 365 days will be £85, or the saving in annual expenses will be £15. Supposing our doctor sells his horse and gig for £100, and borrows £150 at 5 per cent., he will effect a most advantageous economy. In this latter calculation depreciation and repairs have been placed at 12½ per cent. and wages at £50, but while an experienced coachman is necessary for a valuable horse, an intelligent youth could easily manage a motor-car, and so in this particular case it would be sound economy to purchase one.

We should point out that, although we have allowed for depreciation in the motor-van and in the horse-drawn vehicle, yet this is hardly fair, simply because the ordinary cart owner does not, as a rule, set aside either anything for depreciation or for insurance; wealthy firms, owning large numbers of vehicles, of course do. We should also say that our figures are merely indicative, and if they applied to one particular instance they would not necessarily apply to another. Each case must be decided on by its own data. It also must not be forgotten that, when necessary, the motor-vehicle can be worked continuously, and can travel almost an indefinite distance. Running a coach is, on the other hand, very expensive.

We think that enough has been said to show that in any given case in which the data are known with tolerable accuracy Kelvin's Law of Economy enables us to say whether or no it would pay to replace a horse-drawn vehicle by a mechanically-propelled one. In the instances we have given we have said nothing about insurance. This, of course, is a factor depending upon local conditions. Neither have we considered the question of gradients. This also is a local question, and an important one, too. A hilly district might imply the use of a more powerful motor, which would exceed the limit of economy.

G. H. L.

MESSRS. THORNYCROFT'S NEW AUTOMOTOR BOILER.

The object of this invention has been to produce a light, compact, and efficient steam generator such as may be advantageously employed in motor-propelled vehicles or for other purposes. A generator according thereto comprises upper and lower annular chambers connected by water-tubes arranged to form walls of a fire-box adapted to be supplied with fuel through an opening bounded by the upper annular chamber, which opening is furnished with a suitable fire door, and a fire grate being located with its upper surface above the lower annular chamber, below which there is a casing or chamber furnished with a removable ash pan; the flame and products of combustion from the burning fuel on the grate ascend within the fire-box, then proceed laterally through openings left for the purpose between the upper portions of the water tubes of the inner row, then descend between the inner and outer rows of tubes and pass out through spaces left for the purpose between the lower portions of the water tubes of the outer row and thence into a space between the outer row of tubes and an external casing which is or may be in communication with the chamber of an exhausting fan whereby the gaseous products are caused to pass, it may be, into an uptake, or it may be into a funnel or passage leading either to the external atmosphere or elsewhere. The lower side of the upper annular chamber and the upper side of the lower annular chamber constitute tube plates, and the alternate tubes of each row are bent so that their respective ends are at a greater distance radially from the vertical axis of the fire-box than the corresponding ends of the tubes juxtaposed to them. This arrangement obviates excessive weakening of the tube plates by forming the holes therethrough unduly close to one another; it also provides the openings where necessary for the passage of the hot gases between the tubes. Where the gases are not to pass through openings formed in the manner described, rings are provided which form closures to the openings in question. In communication with the upper annular chamber there may be provided a steam dome and separator comprising a vertical steam pipe that is in communication with the steam space of the annular chamber, and has arranged centrally within it a relatively small open-ended pipe, the lower end of which is below the level of the water in the upper annular chamber. This small pipe is perforated at intervals of its length and has attached to it a corresponding number of separating devices, each comprising a lower funnel or cup-shaped part of less diameter than the steam pipe and adapted to conduct any water flowing into it towards one of the perforated parts of the central pipe and preferably provided with a separator of this kind of considerable height.

Referring to the accompanying illustrative drawings—

Fig. 1 shows in central vertical section a steam generator according to this invention.

Fig. 2 shows a plan of the generator, partly in section.

Figs. 3 and 4 are a vertical section and a plan respectively of a steam dome and separator, and Fig. 5 is a developed face-view of the upper part.

The upper annular steam and water chamber is represented as being constructed of two main parts, namely, an annular part, 1, of U section with outward flanges, 2, which may be of cast metal or may be of pressed steel, and an annular tube plate, 3

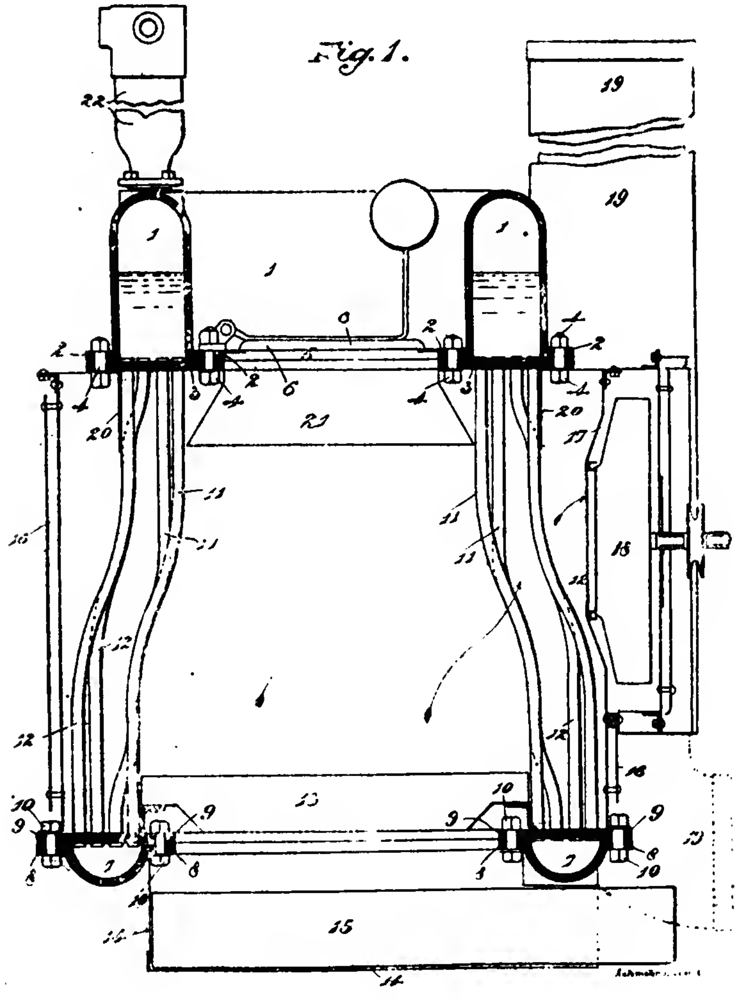

Fig. 1.

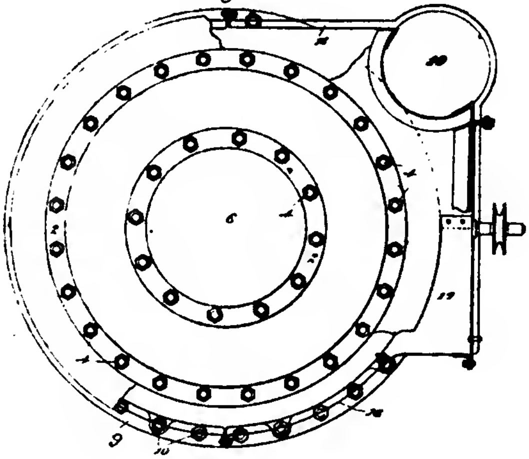

Fig. 2.

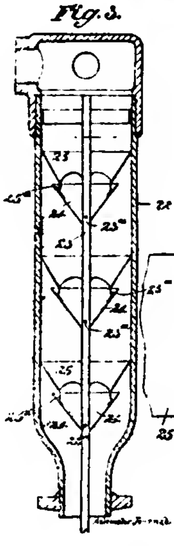

Fig. 3.

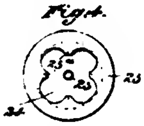

Fig. 4.

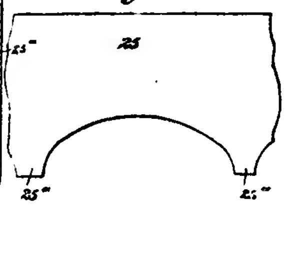

Fig. 6.

an upper truncated cone-shaped part, the upper edge of which is in contact with the wall of the steam pipe and the lower edge of which is somewhat above and of less diameter than the upper edge of the lower part; the upper part is supported on the lower by legs preferably so formed as to form guides down which the water flows. With this arrangement the steam and water is deflected by the lower part of each separating device against the wall of the steam pipe and the back or outside of the upper part, the steam passing under the lower edge of the latter, whilst the separated water flows down the back of the upper part into the lower part, whence it passes through the perforations into the central pipe back to the water space of the upper annular chamber. For use on a vehicle the generator is to which the part, 1, is connected by bolts, 4, passing through its flanges; 5 is the opening through which fuel is fed, and 6 the fire door, which is counter-weighted, so that it will remain open without being held.

The lower annular water chamber resembles the upper annular chamber, but is much shallower, and comprises an annular part, 7, of U or channel section, with flanges, 8, and an annular tube plate, 9, these being secured together by bolts, 10.

The upper and lower annular chambers are connected by water tubes, 11 and 12, the construction and arrangement of which will be understood from the description already given, aided by reference to the drawings.

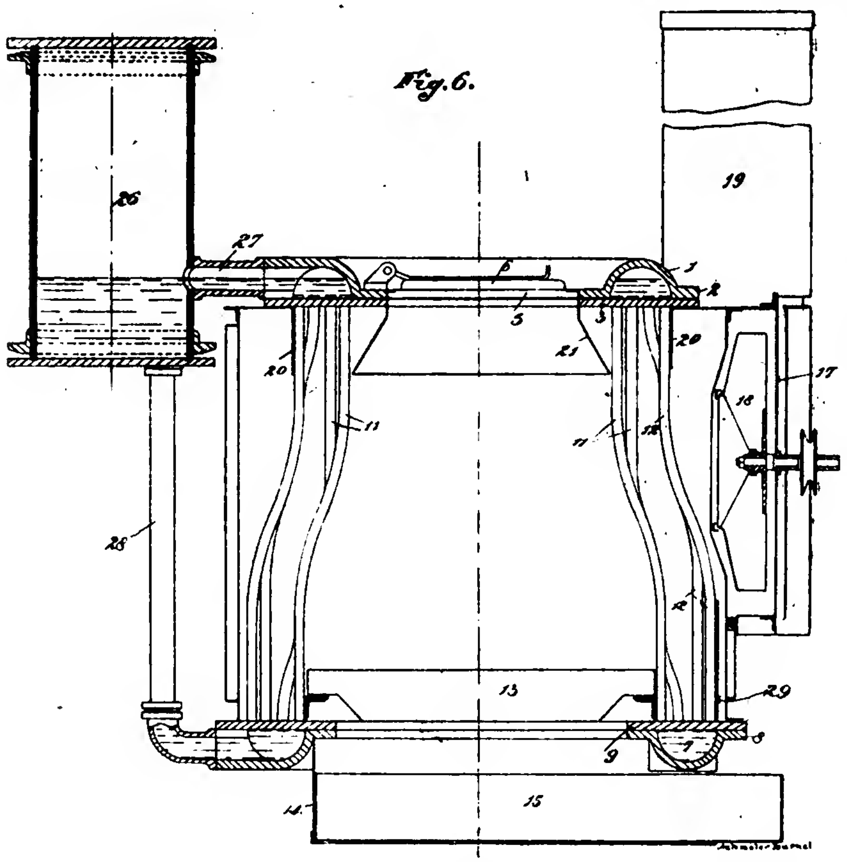
In the example the tubes, 11, constitute the inner row, and the tubes, 12, the outer row, but there might be more rows; 13 is the fire grate, and 14 the chamber or casing below it; 15 is the movable ash pan; 16 is the outer casing of the generator; 17 the fan casing; 18 the fan, whose blades are or may be, as represented, straight and radial, so as to have an exhausting action whether driven backwards or forwards; 19 is the funnel, which may be connected to the fan casing in full lines in Fig. 1, or the fan may discharge the products of combustion downwardly into a passage or flue as indicated by dotted lines. The course of the products of combustion is indicated by arrows; they ascend to the upper part of the firebox, pass outward radially through the spaces between the upper parts of the tubes, 11, then descend through the space between the two rows of tubes, from the bottom of which they again pass outward radially through the spaces between the lower parts of the tubes, 12, into the space between them and the casing, 16, whence they pass to the funnel or flue. If a fan be employed, as in the example, which is necessary when the funnel cannot be made high enough to create sufficient draught, the products of combustion are drawn through the fan casing and discharged either into a funnel or downwardly to a flue; 20 is a ring arranged opposite to those portions of the tubes of a row between which there are openings through which the passage of hot gases is to be prevented. In the case of a boiler with more than two rows of tubes other rings, 20, would be provided where necessary; 21 is a baffle plate for preventing the flame coming directly into contact with the tube plate, 3.

22 is the steam pipe forming a steam dome and containing a central open-ended pipe, 23 (*see* Figs. 3 and 4) (which may be of larger diameter than the drawings indicate); it is perforated at 23ᵃ; to it are attached separating devices, each comprising a lower part, 24, and an upper part, 25, that is formed with legs, 25ᵃ, and has the portions of its lower edge that are between the legs suitably curved (*see* Fig. 5), for the purpose of causing the separated water to flow towards and down the said legs, thereby leaving a free passage for the separated steam and obviating liability of the steam and water to become again mixed. The legs, 25ᵃ, may, if desired, be formed with external grooves, which serve as channels for the water.

The fire bars may with advantage be riveted together in separate groups, so that when it is necessary to clean the fire the central group can be removed, by pulling it out with a firing tool, and the clinkered fire be pushed through the opening thus formed in the grate and allowed to fall into the ash-pan.

Fig. 6 is a view, corresponding to Fig. 1, of a modified construction of generator, in which the capacity of the upper steam and water chamber is comparatively small, and a steam and water cylinder or drum, 26, in connection therewith, is provided. It is in communication through a pipe, 27, with the steam and water chamber, and through a downtake tube, 28, with the lower annular water chamber. In this case a steam separator may be dispensed with, steam being led away from the upper part of the cylinder or drum, 26. In order to ensure as far as possible that the passage of the products of combustion shall take place evenly around the fire-box and not by a short course to the fan or chimney, a plate, such as 29, Fig. 6, may be arranged to extend partly along the outer row of tubes.

Fig. 6.



The following claims are made in the Patent, which is numbered 8326 of 1897:—

(1) A steam generator in which an upper annular combined steam and water space, with steam dome and annular tube plate, opening for feeding fuel, fire door and baffle, a lower annular water chamber with tube plate, connecting walls of water tubes, a fire grate, a chamber or casing below it, an ash pan, an outer casing and hot gas arresting ring or rings, are constructed, combined and relatively arranged substantially as hereinbefore described and illustrated in the accompanying drawings, whether a funnel or fan arranged in a suitable casing be employed for producing the requisite draught, as set forth.

(2) The improved steam generator shown in and described with reference to Fig. 6 of the accompanying drawings.

(3) A steam generator of the kind referred to in Claim 1, provided with combined steam dome and separator, substantially such as hereinbefore described and illustrated more particularly in Figs. 3, 4, and 5 of the drawings.

AT a recent meeting of the directors of the Midland Cycle and Motor-Car Exhibition Company (Limited), it was decided to hold the second show in Bingley Hall, Birmingham, from January 20th to January 29th, 1898. The management intends making great efforts to gather together a goodly number of motor vehicles and thereby make this exhibition a bigger success, if possible, even than last year.

THE motor-car is an accomplished fact in the streets of London, but why have the builders designed the cabs on the pattern of the abominable four-wheeler? Originality is certainly not the quality of our times. Before long, now that Englishmen have taken the first step which they are invariably so slow to take, a multitude of private motor-carriages will come upon the streets, for the saving as regards horses and the keep of horses must be considerable. For whom is reserved the distinction of being the first to attend a Drawing Room in a motor-carriage?—*Graphic.*

SIR CHAS. DANCE'S STEAM CARRIAGES, 1831.

IN view of the present development of automobilism, and having regard to the recent French trials and the report thereon by the Self-Propelled Traffic Association, the following article by Mr. W. Fletcher, the well-known writer on horseless traction, and which appeared in the *Mechanical World*, on November 22nd, 1895, will be of interest :—

We purpose in this article, says Mr. Fletcher, to chronicle Sir Charles W. Dance's achievements with steam carriages on common roads more than 60 years ago.

In 1830 Sir Charles Dance ordered three steam drags of Mr. Gurney. These locomotives were completed and ready for the road at the beginuing of the following year. The engines made to Sir Charles's order were very different machines to those that Mr. Gurney constructed for his own experimental purposes.* In all cases Gurney made his steam carriages self-contained—the coach, the engine, the boiler, and the rest of the apparatus were all mounted upon the same frame and travelling wheels.

The steam drags made for Sir Charles Dance are shown in Figs. 1 and 2. From these illustrations it will be seen that the double-cylinder engine was placed under the body of the machine, and acted direct on to the cranked hind axle. The slide valves were actuated by eccentrics, and the steam pressure employed was 70 lbs. per square inch. One writer of that period, when referring to the question of separate steam drags, said : "When steam conveyances become the regular means of inland communication we may expect the public to prefer travelling by a distinct carriage attached to the steamer, and to seek for the greatest expedition which may be maintained with safety and economy." The owners of such conveyances can more readily carry a greater number of passengers. The coach can be varied in size, but the steam drag must all be of one size and pattern, which is a matter of great moment where repairs are requisite.

In February, 1831, Sir Charles Dance commenced running a steam carriage between Gloucester and Cheltenham, and continued to do so daily for several months, with a fair amount of success and regularity. There were three drags employed, which ran between the places named four times a day for four months, from February 21st to June 22nd, 1831, during which time they conveyed nearly 3,000 passengers, and travelled about 4,000 miles. They performed the distance (nine miles) in from 40 to 50 minutes. There were sometimes delays owing to defective tubes in the boiler, which prolonged the time, but no accident or injury ever happened to any person whatever ; the engines were never out of order, and showed little signs of wear. Sir Charles Dance said : "Steam carriages can be worked profitably so as to carry passengers for one-half the price at present charged by horse coaches." Obstacles are generally thrown in the way of a new invention, particularly if it is likely to produce important results and affect the interests of some individuals by its success. Many objections were raised by many classes of people. Some persons said the steam carriages would injure agriculture, destroy the roads, and that removing horses would ruin the farmers. To which Sir Charles replied that "the land which is used to keep one horse would keep eight people, and, consequently, that the removal of 1,000 horses would feed 8,000 people ; that the cheap and expeditious mode of conveying passengers and carrying everything to market would tend to the welfare of all classes." The trustees of the Cheltenham and Gloucester road were urged by steam carriage opponents to concoct such measures as would put an end to the running of the steam road conveyances. In compliance with this request, large heaps of stones were laid across the road about four miles from Gloucester, 18 inches deep. The steam-carriage passed over these twice with considerable difficulty. The steamer was, in consequence of this obstruction, 80 minutes in making the journey from Cheltenham to Gloucester with 17 passengers. In crossing the stones the third time, with 16 passengess behind, the axle of the drag was broken. Not only were the steam

FIG. 1.

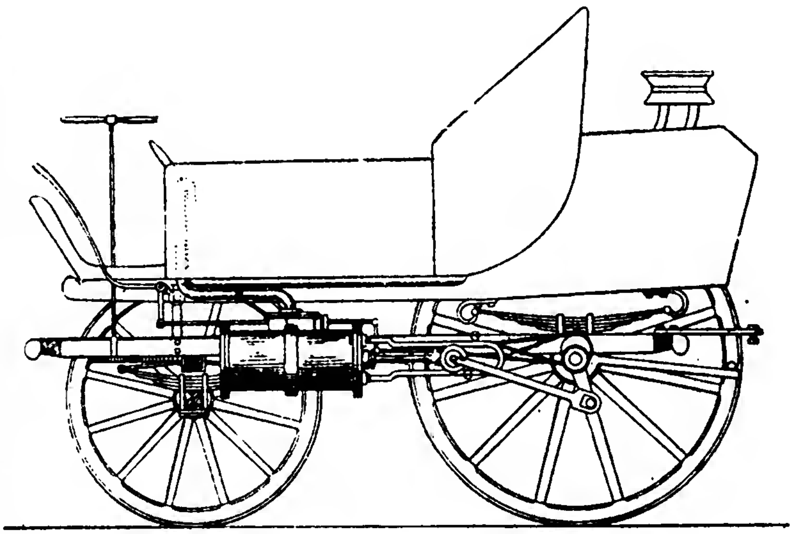


FIG. 2.

carriages delayed and injured by this deliberate and hostile proceeding, but the horse-drawn coaches were stopped in the stones, the mail coach was delayed, and a fine four-horsed coach was brought up, and, in whipping to get through, broke the harness. In the meantime a number of turnpike bills were rushed through Parliament granting tolls upon steam carriages, which were intended to be a complete prohibition ; and the Cheltenham Trust was one of the number. Sir Charles Dance relinquished the steam carriage business in that part of the country, and took his carriages to London.

In Gordon's work on locomotion a tabular account is given of the 315 journeys made by the carriages between Gloucester and Cheltenham, which we have not space to print.

The disappointment to Sir Charles occasioned by an ignorant

* Two of Gurney's steam coaches are illustrated in "Steam on Common Roads," by W. Fletcher. (London : E. and F. N. Spon.)

and prejudiced party who had opposed him in every way, was sufficient reason for his retirement from the field for some time.

In April, 1832, he patented a boiler consisting of coils of drawn iron tubing placed above the fire in a horizontal direction. The firebars were also formed of tubes; the ends of the tubes were joined to a water space placed all round the fire. The method of obtaining a good circulation of the water in the tubes is explained in the Patent Specification.

In 1833, Sir Charles Dance sent one of his steam carriages to Messrs. Maudslay, Sons, and Field's works to be altered, and as Gurney's boiler was about the only mechanical trouble he had to encounter, we are not surprised to find another boiler patented in August, 1833, by Sir Charles Dance and Joshua Field. This new boiler was composed of 30 sets of tubes enclosed within a wagon-headed boiler having a short vertical chimney. The lower portions of the water loops are horizontal, and form the bars whereon the fuel is laid. The tubes are suitably bent for forming the sides of the fireplace, and crossing in an inclined position above the fire, the products of combustion pass through the spaces between the tubes in their exit to the chimney. Each pipe opens at its upper and lower ends into horizontal tubes, and the water in the bent pipes has free communication throughout the series.

After the new boiler had been fitted to the steam drag, and the engine altered in some minor particulars by Messrs. Maudslay and Co., a short experimental run was accomplished at the rate of 16 miles an hour on September 18th, 1833. A trip to Brighton and back was afterwards undertaken. The outward journey of 52 miles took about 5¼ hours. The return journey was run in less than five hours. The following persons rode in the coach:—Sir Charles Dance, Mr. Field, Mr. Maudslay, Mr. A. Gordon, Mr. Carpmael, five other friends of Sir Charles Dance, Mr. Ricardo, and Mr. Busby; other individuals were taken up and put down on the road. In October, 1833, several other runs were made at 11 miles an hour. An improved locomotive and carriage were put upon the road between Wellington Street, Waterloo Bridge, and Greenwich, where they continued to run for a fortnight, with a view of showing the public in London what could be done. There was never any intention on the part of the owner of making it a permanent mode of conveyance, and therefore he kept the company select by charging half-a-crown for tickets each way.

Several engineers were anxious to have the carriage tried on the Holyhead line of turnpike road to Birmingham. The following report was the consequence:—

Report of the Result of an Experimental Journey upon a Mail-Coach Line of the Holyhead Road, in Sir Charles Dance's Steam Carriage, on November the 1*st*, 1833.

"Public attention having been attracted with the practicability of travelling with locomotive engines upon ordinary roads, by a report of a Committee of the House of Commons, 12th October, 1831, stating that, in the opinion of the Committee the practicability of such mode of travelling had been fully established, we were desirous of personally making an experiment of the facility with which a carriage of the above description could perform a journey of considerable length, and having selected the mail-coach line of the Holyhead road for the purpose of such experiment, we made an arrangement with Sir Charles Dance for the use of his steam carriage on the 1st November. Before the carriage had proceeded six miles one of the tubes of the boiler was found to leak so fast as to render repair necessary. It was also apparent that the size of the engine was not sufficient to carry so great a weight along a heavy road at any high velocity.

"The weather was by no means favourable, there having been much rain, so as to make the road heavy, added to which the winter coating of new materials had in many places been laid upon the road. Notwithstanding these obstacles, upon our arrival at Stony Stratford, 52½ miles from town, the average rate of travelling had been seven miles an hour. There can be no doubt that with a well-constructed engine of greater power, a steam carriage conveyance between London and Birmingham at a velocity *unattainable by horses*, and limited only by safety, might be undertaken with great advantage to the public, more particularly if, as might obviously be the case, without interfering with the general use of the road, a portion of it were to be prepared and kept in a state most suitable for travelling in locomotive steam carriages. Signed by eleven engineers, six of whom were Thomas Telford, President of the Institution of Civil Engineers; Bryan Donkin, Timothy Bramah, Joshua Field, Alexander Gordon, Wm. Carpmael. London, November 1833."

We may add a few particulars. The drag had two cylinders 7 inches in diameter and 16-inch stroke. The boiler pressure was 100 lbs. per square inch. The weight of the drag was 3 tons 5 cwt. The omnibus and load weighed 2 tons 15 cwt., making the total load 6 tons.

After the trial on the Holyhead road Sir Charles Dance and his carriages appear to have vanished. We have no tidings of any work done later than 1834. With such a heavy engine and coach the wonder is that Sir Charles succeeded in running at 11 miles an hour. Their great weight must have interfered in many ways with a longer and more successful career.

THE NEW FRENCH REGULATIONS FOR AUTOMOTORS.

The Prefect of Police for Seine, M. Lépine, has recently signed an ordinance regulating the circulation of automobiles in the Seine Department. The document examines "the use, on the public way, of vehicles worked by motor power, and also of those which are used for the making of railroads."

Section I.

Art. 1.—No vehicle worked by motor power or those which are used for making railroads can be set or maintained in use without our authority, which the owner must ask for. The owner must understand that this authority can be cancelled at any time on the motion of the engineers.

Art. 2.—This authority will be written out on a stamped paper. It is worded thus:—

1st. The principal dimensions and weight of the vehicle, the weight of the luggage, and the maximum charge per axle.
2nd. Description of the motor system, the materials for working it must be specified, conditions for use, definition of the appliances for stopping and warning.
3rd. The names and residences of the constructors of the vehicle, its motor machinery, and its appliances for stoppage.
4th. The proofs and verifications of the persons who have constructed and examined it.
5th. Its number (vehicles made by the same firm should have a special numbering for this firm and stating each machine clearly).
6th. The use to which it is to be put.
7th. The public ways on which it will run.
8th. The name of its depôt or where it is kept.

The application must be accompanied by complete drawings of the vehicle, of the motor system, and the machinery for operating the brakes.

Art. 3.—This application must be sent to the chief engineer, who inspects steam machinery for the Seine Department. He will himself inspect the vehicle thoroughly, so as to be quite satisfied, according to Section II, that there will be no danger in using it. He will have several experiments made to test the working of the motor and to verify the efficacy of the brakes.

Art. 4.—The authority will be set forth on a special certificate worded like the present document. Special instructions for heavy carriages (3,000 or 4,000 kilos.) will be added, if necessary.

Art. 6.—The authority will also fix the maximum speed for in Paris and outside, especially paying regard to the means for stopping. This maximum speed will not exceed 12 kilometres per hour in Paris and in peopled thoroughfares; it can rise to

20 kilometres in open country, but the latter maximum will only be allowed on straight, level, broad roads, which are little frequented. These maximums cannot be surpassed, but the driver of the vehicle may reduce the speeds of the above maximums at any time when circumstances require it.

Art. 7.—In case of a change of ownership, of non-execution of proofs or verifications prescribed by the regulations, the authority is voided, and the vehicle cannot be maintained in use without a new authorisation.

SECTION II.—*Dispositions relating to the Machinery.*

Under this clause are grouped some articles relating to safeguards which ought to be made on the vehicles :—To ensure stoppage of the motor in case of accident ; facility for working the machinery and directing it ; existence of two independent checks, kept in a good condition. Permission will be granted for periodical alterations, and for the necessary verifications to effectuate this. The periodical alterations and repairs to be noticed will be inscribed in detail on the certificate specified in Art. 4.

Art. 17.—Every vehicle worked by motor power must have a metal plate, on which must be written in legible letters the name and residence of its owner and the number accorded by the authority. This plate should be placed on the left side of the vehicle, and must not be covered up.

SECTION III.—*Regulations relating to the Keeping and the Working of Carriages.*

Art. 18.—No one will be allowed to keep a vehicle worked by motor machinery specified by the present document if he does not possess a certificate for competency issued by us to that effect, and stating the kind of motor-vehicle. No one of 21 years of age or under will be allowed a certificate. The candidate must produce his certificate of birth and two photographs (each photograph must be 2 centimetres broad and 3 centimetres long), also an authentic certificate of residence. One of these photographs will be annexed to the certificate. Every candidate must show a proof to the chief engineer or his delegate (1) that he possesses the necessary experience for the prompt and sure use of the machinery in motion and at rest, and for the direction of the vehicle ; (2) that he is capable of knowing if all the machinery is in a good condition, and of taking every precaution against explosions and other accidents; (3) that he could, if necessary, repair a slight damage while travelling.

The certificates thus delivered are revocable. For vehicles worked by steam these certificates take the place of those set forth in Art. 12 in the document of January 3rd, 1888, referring to the working of steam machinery on the public way.

The driver of the vehicle must conform to some of the regulations which regulate the drivers of horse-carriages, especially those relating to the precautions to be observed when in motion and at rest ; to keep to the right, &c. ; to go slowly in crowded thoroughfares ; to be provided with a horn or trumpet. Vehicles should also have bells. Vehicles are not allowed to remain stationary on the public way. A vehicle worked by motor machinery will not be allowed to tow other carriages.

In case of accident to persons—a notable material accident or explosion—the owner of the vehicle or the driver must immediately inform us and the Commissioner of the Police. The damaged machinery and its fragments can only be displaced by major force, or by permission of the Commissioner of the Police, before the close of the inquests.

SECTION IV.—*General Regulations.*

Art. 32.—Vehicles worked by motor power should have everything that is applicable to them submitted (1) to the dispositions of the laws and regulations specified in Sections I and III in the decree of the 10th August, 1852 ; (2) if the motor is a steam motor, to the dispositions of the laws and regulations on steam machinery in the decree of the 30th April, 1880, and the document of the Prefect of the Police of January 3rd, 1888 ; also to the Articles 14 and 15 of this document.

Such are the principal prescriptions of this document, which at present only applies to the Seine Department. The Minister of the Public Works can make it a general rule for all France.

REPORT OF THE SELF-PROPELLED TRAFFIC ASSOCIATION ON THE FRENCH TRIALS.

THIS report only came to hand on the eve of the publication of our last number, and hence we had not time to examine it critically. Having since had the opportunity we may say at once that on the whole it is a fair and unprejudiced account of what occurred at the trials, and many of its conclusions will very generally be concurred in. The deputation that attended the trials on behalf of the Liverpool branch of the S.P.T.A. included a well-known engineer and naval architect, who, from his long connection with the construction and classification of shipping, was not likely to be impressed with machinery of any sort that was not solidly and substantially built. After giving a "log" of the performances of the various motors, the report discusses De Dion and Bouton's system. Speaking of the boiler it says :—

It appeared to be a good practical boiler and, considering its small capacity for water, the feed-service was kept well under control. The feed-water tanks hold about 100 gallons.

and of the engine :—

A horizontal compound engine is used, and provision is made for the admission of high-pressure steam to the low-pressure cylinder, for hill-climbing and emergencies. The gearing consists of spur wheels, two ratios, which may be applied as the work to be done requires, being provided. The rear road-wheels run loose on the axle, each being driven by means of four steel arms which extend from the axle and are secured to four of the spokes at points about mid way between the boss and the rim of the wheel.

The consumption of coke and water was :—

Coke	7·6 lbs. per mile.
Water	4·4 gals. „

The tare of the omnibus is 4 tons.

The De Dion and Bouton system, whilst exceedingly ingenious, is, in our opinion, open to the practical objection that it would require a skilled attendant and an assistant for each motor. The attention of the driver is so much absorbed with the control of the machine that, unless he had another man with him on the look-out and to sound the alarm-signal, especially in crowded thoroughfares, we think it would be difficult to secure safe driving.

As regards the prices of these vehicles they are stated as being £580 for the tractor, No. 13, and £880 for the omnibus, No. 14, at works. The report then deals with the Scotte system. After describing the machinery the report continues :—

The three Scotte vehicles (Nos. 1, 2, and 3) ran throughout the trials with good results and remarkable regularity, but the remarks as to the necessity for a skilled attendant and an assistant apply to this system as much as to that of De Dion and Bouton.

Omnibus No. 1 returned the following consumption over Course C :—

Coke	13·0 lbs. per mile.
Water	9·8 gals. „
Price of motor-wagon	£380 at works, Paris.
„ trail-wagon	60 „ „

Speaking of the other motors the report says :—

All the machines exhibited very great ingenuity of design and construction, one of the most interesting being Panhard and Levassor's Omnibus (No. 10). This vehicle is fitted with a four-cylinder vertical oil-engine carried in front under the box seat. The crank and counter-shafts are longitudinal with four sets of spur-wheels for variable speed, motion being imparted by a bevel-wheel to a transverse shaft which carries the compensating gear and sprocket-wheels for driving the rear road wheels by link chains. This vehicle consumes only about 1½ pints of petroleum spirit (0·680 S.G.) per mile but, in common with all oil-motored carriages, has the serious disadvantage of very considerable vibration when standing or running at a low rate of speed.

It was an instruction to the deputation to inspect the Paris tramways, and the next part of the report is occupied with a description of the Serpollet system. We reproduce this elsewhere. Passing on to the conclusions, the report says :—

Reviewing the numerous systems and vehicles that came under our notice, we are of opinion that—

1. Scotte's and De Dion's vehicles are the only ones we saw capable of dealing with loads such as we in Liverpool require to move.
2. Serpollet's system has been admirably worked out for tramcars, but, owing to the demand for these, not much has yet been achieved in its application to ordinary road vehicles.

3. Oil-engines (internal combustion), using petroleum spirit, are developed to a high degree of lightness and economy for pleasure carriages and vehicles of a small gross weight.
4. There can be no doubt as to the popular feeling in France, where the liveliest interest is evinced in all matters appertaining to automotors, but it is more from the point of view of pleasure-seekers with a novelty than of business men with work to do. At the same time, the practical carrying aspect of the question is attracting attention, and efforts are being made to produce vehicles for the transport of goods. No thoroughly satisfactory vehicle for really heavy traffic was, however, produced at these trials.
5. As our investigations appear to show that no heavy vehicle in France has yet reached such a stage of development as to be suitable for the requirements of this district, we are of opinion that the public trials which the Association proposes to hold next spring should be proceeded with, in order to ascertain the actual position of English effort to produce self-propelled vehicles for heavy traffic on common roads.
6. As now constructed, neither Scotte's nor De Dion's vehicles would be of any use in this country, owing to the tare weights being in excess of those allowed under the provisions of the Locomotives on Highways Act, 1896. These machines unquestionably have in them the elements of practical success.
7. Whilst our conclusions are not entirely favourable to the motor-wagons put forward on this occasion for the transport of heavy goods, there is no doubt that Scotte's and De Dion's systems are efficient and economical for passenger services, and that Serpollet's tramcar system is a proved success.

It will be observed that the report, in discussing the De Dion and Scotte systems, condemned these motors because each "would require a skilled attendant and an assistant." Yet conclusion No. 1 admits that these are the only ones the deputation saw capable of doing such work as is required in Liverpool. Admitting for the moment that a "skilled" (*sic*) attendant is necessary, is it a logical and economical proposition to advance, viz., that because by this machine economical transport is effected, yet it must not be used because it requires a skilled attendant? The fact is that far too much stress is put upon the question of skilled attendance, and to pine after the ideal motor which can be handled by a person devoid of any skill is like sighing after the Elysian Fields. What is meant by a "skilled attendant"? Skill is required to work a sewing machine, a quick-firing gun, an automobile torpedo, or a coster's barrow. The amount of intelligence required to work a steam boiler is really very little, especially when there is trained supervision. Sometimes the driver of an express locomotive is termed a skilled man, but given ordinary intelligence and the least mechanical perception and a Chinese coolie or a half-caste nigger is as good on the foot-plate as anyone. If this assertion is questioned, it is only necessary to mention that in Central Africa, and America, in the East Indies the drivers of the automotors, whether these be steam launches, locomotives, or agricultural machines, are "natives," who have merely natural common-sense to guide them. Again, consider the large fleets of fishing automotors, *i.e.*, the steam trawlers; the boilers and engines of these vessels are handled by the least trained (in a mechanical sense) of our workers. A fisher-lad, with absolutely no mechanical training whatever, will get up steam, handle the winch, and maintain the feed with no other instruction than that which he gets by knowing that he has got to do it. We must protest against this bogey of the skilled attendant. In such machinery as torpedo-boat engines and boilers, skill in firing and handling is unquestionably necessary, but agricultural labourers find no difficulty in managing portable engines and boilers, and we cannot admit that anything more than a fair share of ordinary common-sense and clear-headedness is required of the driver of an automotor carriage. As touching upon this question of skill, the report mentions that in Paris an ordinary driver is entrusted with a Serpollet car after a week's teaching by one of his mates. For the report, then, to condemn the De Dion and Scotte motors because of the skilled attendant seems to us hardly logical.

After having expressed itself as it has on the merits and objections to the De Dion and Scotte systems the report says in paragraph 5:—"No thoroughly satisfactory vehicle for really heavy traffic was, however, produced at these trials." If satisfaction is dependent upon the amount of weight moved at a certain speed and with the expenditure of a certain amount of energy, then we think the conclusion arrived at is not a sound one, as it is at variance with facts. Both these motors have abundantly demonstrated their ability to handle heavy loads with great economy. If, however, satisfaction hinges upon the skilled attendant the conclusion is also erroneous, because as we have shown the skill required is of an exceedingly elementary kind. Certainly the attendants at Versailles were skilled mechanics, and as we remarked in our last issue, not a little of the success was due to their efforts, but we saw nothing about any of the steam motors that would deter us from entrusting them to any intelligent ploughman or fisherman. We would remark that to be a good ploughman or fisherman requires good intelligence and skill, but we have yet to learn that a steam motor-car requires skill of a superior degree.

As showing that our criticisms are shared by others, we requested two eminent engineers, both ardent automobilists, to express their opinion on the report before us; the one cordially endorses every word of it, and the other writes:—"I do not agree with the conclusion (No. 4). It is too general . . . . . . that they will not do for the Liverpool requirements I quite agree, but is it desirable that the denunciation of the vehicles 'for really heavy traffic' should have been accompanied by the admission that for loads of from 3 to 5 tons, or at all events 3 to 4½ tons, motor-wagons were exhibited by Scotte, which are of a really useful and practical kind. Of course they are susceptible of improvement, if it be only the means required for making a gear case possible, but even as they are, they would in many cases conduct a traffic at a cost considerably under that for horses."

With the other conclusion we quite agree, and we hope that the Self-Propelled Traffic Association will by next spring succeed in evolving the "really satisfactory motor."

SOUTHALL'S PATENT "IDEAL" OIL-ENGINES.

Among the many varieties of oil-motors few can compare with the Southall for simplicity in design and efficiency in action. This motor, which we illustrate, is made by Messrs. Hardy and Podmore (Limited), of Worcester Foundry, Worcester. It is a heavy oil-motor, using ordinary lamp oil, a fact which will at once commend it to automobilists, and works on the Otto cycle. No spirit is either required for starting, which is another good point in its favour. These motors start easily and with certainty, have no pumps or other fine parts, and are thus specially suitable for use by ordinary unskilled persons. The chief features in them are:—

1st. The patent wick feed, giving an absolutely regular supply, not of liquid oil but of oil-gas or very fine oil-spray.
2nd. The ignition of the charges by a piece of metal isolated by non-conducting material, which, after the engine has run a few minutes, becomes heated to a higher temperature than the rest of the engine, thus allowing the vaporiser to remain at a lower temperature than would be practicable if its heat had to perform the ignitions.

Referring to the accompanying drawings:—

Fig. 1 is a part longitudinal section.
Fig. 2, a back elevation.
Fig. 3, a back elevation of the wick.
Fig. 4, a part plan, explaining the governing.
Fig. 5, a part sectional elevation, explaining the governing.

To start the engine, fill the reservoir, A, with oil and screw down its inlet cap absolutely air-tight, then open the tap, B, which allows the oil to enter the trough, C, until it has reached the level of the inlet, at which level the oil in the trough, C, will automatically maintain itself.

See that the two stoppers, D and E, are removed, then having trimmed the lamp, F, with loose cotton waste saturated with petroleum, light it and by means of the fan provided for the purpose, blow same fiercely from four to six minutes.

This operation causes the flame to pass round an annular flue, G, formed round the vaporiser, L, heating it and at the

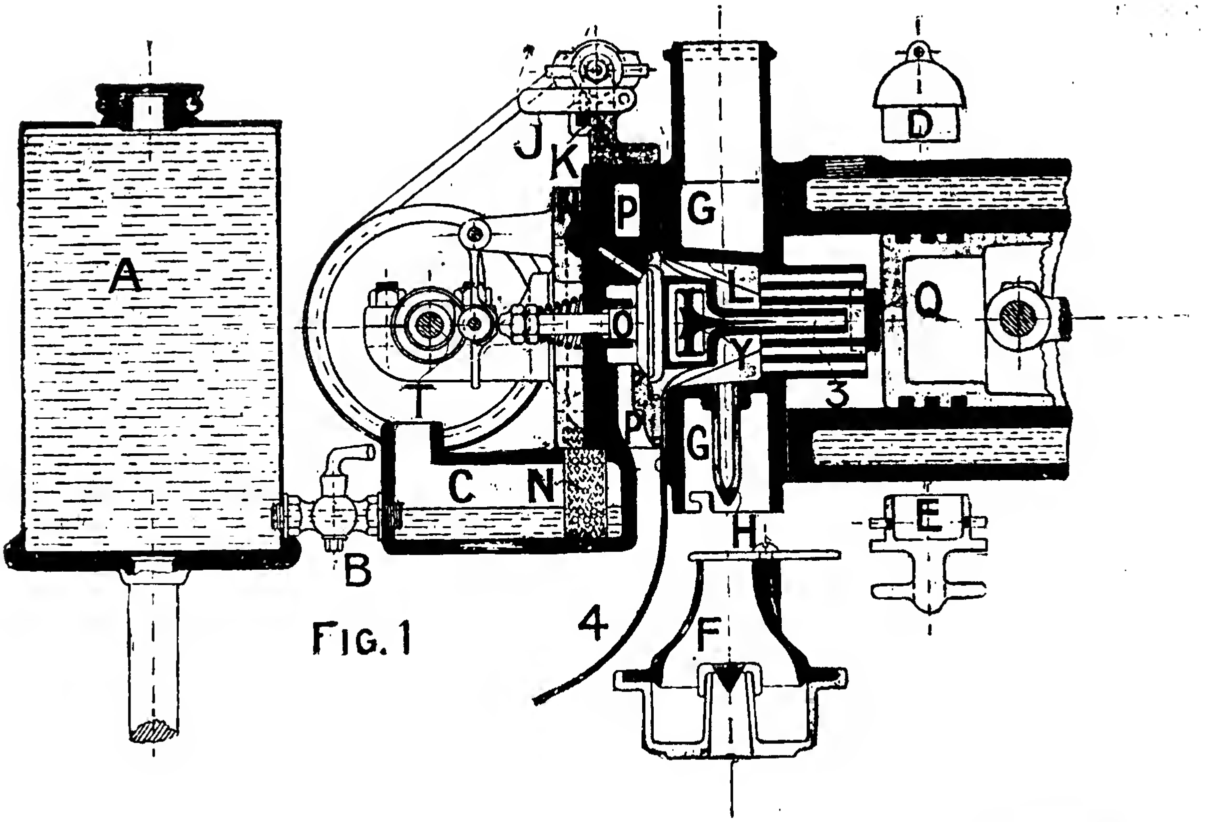

FIG. 1

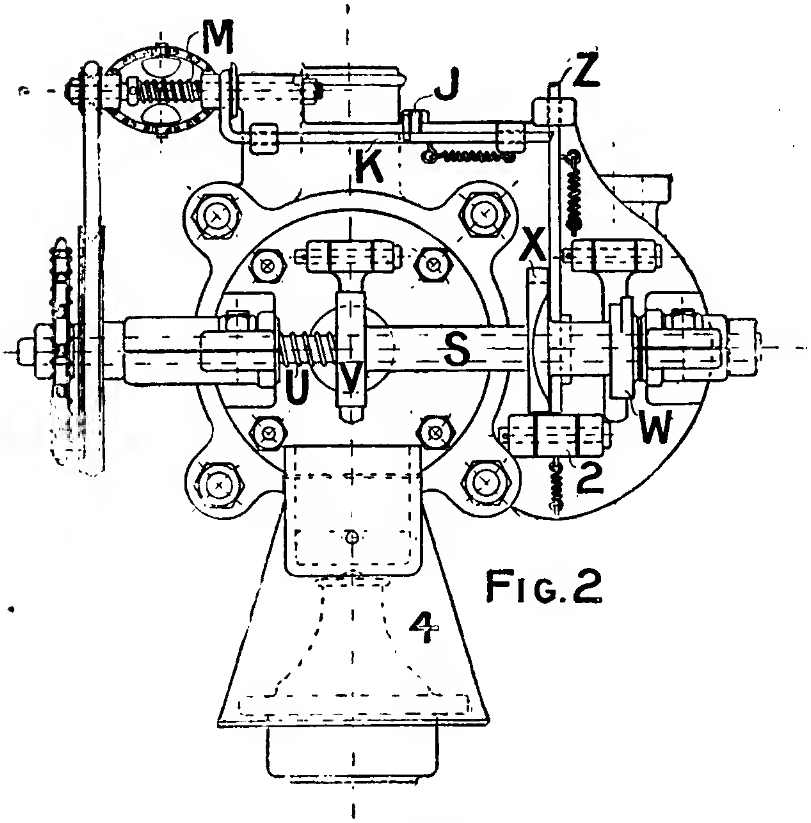

FIG. 2

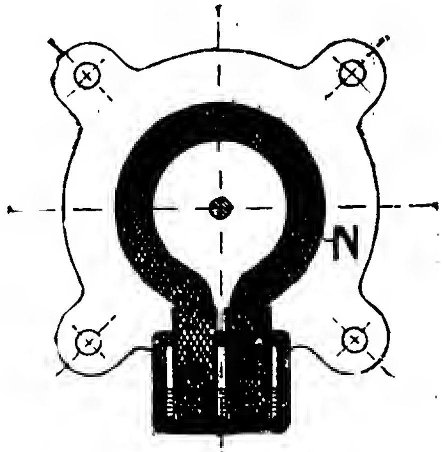

FIG. 3

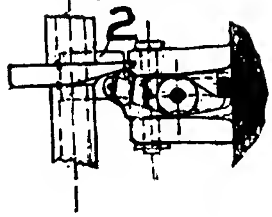
FIG. 4

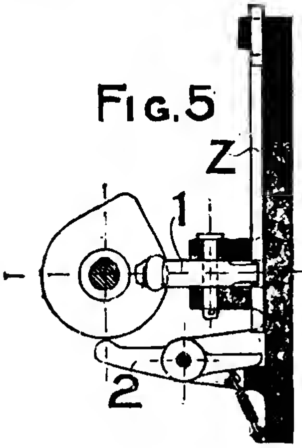


SECTIONAL VIEWS OF SOUTHALL'S PATENT "IDEAL OIL-ENGINE.

same time a tube, H, which serves to perform the ignitions for a short period at starting.

Whilst blowing see that the small lever, J, is turned down behind a small pin projecting upwards from the governor bar, K, as this puts the governor in continuous action and reduces the compression for starting. After blowing for the above period give the fly-wheel a few rapid turns, then throw the lever, J, up and ignitions will commence. Continue to operate the fan for a few minutes so as to get a good start, after which extinguish the lamp, F, closing the inlet and outlet of the flue, G, with the stoppers, D, E, the engine will then continue to run as long as there is any oil in the reservoir, A. The speed of the engine can be varied within considerable limits by simply putting the spring on the governor, M, in a state of greater or less compression. N is the wick serving to convey the oil from the trough, C, to the vaporiser, L. O is the supply valve controlling the simultaneous admission of air from the passage, P, and oil gas or fine spray from a number of rather long holes, R, connecting the wick, N, with the seat of the valve, O. Q is the exhaust port, controlled by a valve with which the supply valve, O, is operated by cams on a long sleeve, S, carried on and driven by a shaft, T, revolving in suitable bearings at half the speed of the crank shaft, the sleeve, S, being arranged

FIG. 5



Sectional View of Southall's Patent "Ideal" Oil-Engine.

on a feather key, so that when required it can be moved laterally along T, compressing a light spring, U. The cam, V, operates the supply valve, O, cam W the exhaust valve, and cam X, which has cams formed both on its edge and one side, assists in the governing of the engine, which is accomplished by entirely cutting off the charges when the engine exceeds the speed it is set to run at. The governor, M, which is driven from the shaft, T, when the engine exceeds its speed, draws over the bar, K, against the energy of a light spring allowing a spring-urged bar, Z, working in guides to descend into the path of the inner end of a short lever, 1, so pivoted that during the nominal working of the engine it rocks freely backwards and forwards, its outward end urged by a spring weaker than the spring, U, pressing lightly against and following the cam face on the side of the cam, X.

The lever, 1, when its inner end meets the bar, Z, is prevented from rocking, causing the sleeve, S, to move laterally along T, compressing the spring, U, the cam, V, thus misses lifting the supply valve, O, and a different face of the cam, W, acts on the exhaust valve in such a manner as to hold it open during the next out and instroke, thus preventing any suction from being exerted on the supply valve, O. The edge of the cam, X, comes into operation with each revolution of the shaft, T, causing a small lever, 2, to lift the bar, Z, up into its original position, where, if the speed of the engine has been sufficiently reduced, the bar, K, engages in it, holding it up and allowing the sleeve, S, to return by aid of the spring, U, laterally to its normal position, where the cams, V and W, will again perform their normal operations.

The igniter, Y, is a piece of pointed metal isolated in a box casting on non-conducting material, such as asbestos, and having an inlet pipe, 3, the length of which influences the moment of ignition. A baffle, 4, is provided to keep the lamp flame from the trough, C. On a suction stroke occurring, a charge of air and oil-gas or fine spray is drawn into the vaporiser and cylinder through the valve, O, forming an explosive charge which, when compressed, is ignited for a short period at starting by the tube, H, and afterwards by the extra hot piece of metal, Y.

SIGN-POSTS FOR AUTOMOBILISTS.

The Automobile Club of France is nothing if not thorough on all questions relating to automobilism. In order to assist travellers, tourists, and others, it has had erected at various points on the principal route sign-posts, one of which is shown in the accompanying illustration, and which is placed in the village of St. Maclou on the road to Trouville. Information of this kind is calculated to be a great service, especially in cases where fuel or water is running short or night coming on. Similar sign-posts might with advantage be placed on English roads by the county and municipal authorities, but notwithstanding their obvious utility we entertain little expectation of this being done, as it would encourage motor-cars and cyclists to use the roads!

A COVENTRY BOLLÉE.

Mr. T. Hyler-White, of Coventry, sends us an account of the performance of one of these excellent motors. The weight is about $3\frac{1}{2}$ cwt., and is of about $1\frac{1}{2}$ H.P. There are three speeds, viz., 5, 10, and 16 miles per hour. The cost of running is said to be $\frac{1}{4}d.$ per mile. A run was recently made from Coventry to Cheltenham and back, a distance of 116 miles, which was performed in $10\frac{1}{2}$ hours' actual time (including time for meals, &c.). This gives an average speed of a little over 11 miles, but of course the real average speed is much higher, being, we understand, 12·3 miles. The machine is remarkably easy to manage, the steering, starting, and stopping being absolutely controllable, while rough roads and hills are negotiated with no difficulty whatever.

Mr. Hyler-White concludes :—"For a light and handy pleasure vehicle the machine is almost all one could desire, though a little more room, to carry, say, a portmanteau, would be a useful addition. Luggage at present has to be carried on the front footboard."

METHODS OF OBTAINING MOTIVE POWER FOR MOTOR-CARRIAGES.

THE following is a free translation of an article on this question by M. Marcel Deprez, and which recently appeared in the *Génie Civil*:—

It seems at first sight that the only applicable force for automobile vehicles should be the petrol motor, but after looking more deeply into the question it is found that this is not so safe as it seems, and it will be seen in the course of this article that at present steam has great inherent advantages, and that it is of very great use to automobilism. Three years ago, at the first exhibition of automobile carriages, steam was beaten by petrol, and it has been up to the present day. This defeat of steam is very surprising, for it is both powerful and pliant, capable of towing at a speed of 120 kilometres on a level more than 150 tons.

Use of Metal and Indiarubber Springs.—Their "specific power" (*sic*) is really very small, metal springs store work at the rate of 20 kilogrammetres per kilogramme, and indiarubber springs 250 kilogrammetres per kilogramme.

Use of Compressed and Liquefied Gases.—There are special points to notice about compressed air, among these are cleanness and facility to set in motion, &c.; but in order to store a large amount of energy very heavy reservoirs are necessary.

Below is a tabular statement compiled by M. Barbet on the Mékarsky system:—

Particulars of the Compressed Air Locomotive.

Steel reservoirs.
Initial pressure of air: 60 atmospheres.
Elastic strength of the steel employed: 15 kilogrammes per square millimetre.
Weight of reservoir per kilogramme of air: 12 kilogrammes.
Theoretical work indicated by 1 kilogramme of air in the receiver: 20·765 kilogrammetres.
Theoretical efficiency per cent.: 0·65 per cent.
Practical „ „ 0·33 „
Weight of air at 45 atmospheres per kilogramme for a carriage of 12 tons: 12 kilogrammes.
The compressors of the Parisian Company for compressed air give 6·35 kilos. of compressed air at 49 atmospheres per H.P. hour. One kilogramme of air compressed to 45 atmospheres costs ·0072 franc.
The consumption of coal per H.P. hour of the automobile carriages running through the streets is 4·5 kilos.

It is thus seen that a kilogramme of compressed air at 45 atmospheres can supply a theoretical work equivalent to 20·765 kilogrammetres; this air ought really to be compressed in a reservoir to three times the density that it is, which would increase the disposable work per kilogramme of air to only 169·0 kilogrammetres, whilst a kilogramme of petrol would practically produce 750·000 kilogrammetres.

By this rendering it is seen that the necessary work for compressing a kilogramme of air to 45 atmospheres is 39·335 kilogrammetres, corresponding to a theoretical rendering of 65 per cent. M. Barbet admits a practical rendering of 50 per cent.; approximately the final rendering is equal to 33 per cent.

It has already been stated that compressed air to 45 atmospheres cost ·0072 franc per kilo. But following M. Barbet's system, the figure should be doubled in order to allow for fluctuations, for the interest and redeeming of the mortgaged capital; it is also necessary to reckon from the result thus obtained 30 per cent. for the work of lading, re-heating the air, and a possible increase in the initial pressure; therefore the price for a kilogramme of compressed air should be ·020 franc, or 20 francs per ton.

From data obtained on the different tramways worked on the Mékarsky system, the following results have been obtained for the weight of compressed air consumed per kilo-car to seat 10:—

	Kilogrammes.
Paris-Ville-Errard Line	10
St. Augustin-Vincennes Line	12·5
Nantes Tramway	7

This can be rated at the following expense per kilo-car:—

	Francs.
Compressed air	0·200
Fares....	0·074
Maintenance, oil, and coal....	0·071
Total	0·346

Lastly, the consumption of coal per kilo-car is 20 kilos. for a heavy carriage of 12 tons, which is equivalent to an initial consumption of 4·5 kilos. of coal by an automobile carriage per H.P. hour.

Finally, in order to solve this problem of mechanical traction, it will be noticed that compressed air is a very convenient source of power, but at the same time it is the dearest, and its specific power is very small.

Use of Liquefied Gases.—The amount of energy necessary for confining a liquefied gas is proportional to the quantity of heat required to liquefy it, but gases do not possess a heat for evaporation to be compared with water, which for this reason is much preferred for storing heat. Besides, as heat cannot produce so much work from a warm body as a cold, the allowance has to be continually raised, for heat cannot be transformed while working, and this can only be obtained by two methods: either by cooling, by means of a condenser, the gas or steam after having been used in the motor, or by discharging the gas or steam in the atmosphere, which is only allowable for water-steam and those gases from the combustion of coal or petrol. Consequently, not only do liquefied gases, like compressed gases, involve the use of very heavy reservoirs, but they are very inferior in every way to water for using in motors.

Use of Hot Water under Pressure.—This process consists of heating the water in a closed vessel to a temperature of 200° C., this corresponding to a pressure of 15 atmospheres; this storage reservoir supplies heat to a smaller boiler, the steam so produced passing into the cylinder, where it acts on the pistons. This steam is formed at the expense of stored heat in the water of the boiler, which thus serves as a heat reservoir. The temperature of water in the reservoir progressively decreases to 150°, whilst its pressure simultaneously decreases to 5 atmospheres. It can go below 150°; on the other hand it can rise above the initial pressure, 200°. But it is very difficult in this way to store more than 75 available calories per kilo. of water in the reservoir. The weight in kilogrammes of a steel reservoir of 1 cubic metre in capacity is given in the following formula, in which P represents the pressure, and F the stress per square millimetre.

$$W = \frac{P}{F} \times 16{\cdot}000.$$

In the following table are given the weights for reservoirs having a capacity of 1 metre cube for various pressures:—

Temperature of Water under Pressure.

—	200°	225°	250°	275°	300°
Absolute pressure in atmospheres	15	25	39	59	86
Actual pressure in atmospheres	14	24	34	58	85
Weight of reservoirs in kilos. ...	224	384	608	928	1,360
Quantity of heat in calories, in water above 150°	50·000	75·000	100·000	125·000	150·000
Quantity of heat in calories contained in metal	1·340	3·460	7·300	13·900	24·500
Quantity of total stored heat ...	51·340	78·460	107·300	133·900	174·500
Total weight in kilogrammes ...	1,224	1,384	1,608	1,928	2,360
Quantity of stored heat in kilogrammes	42	57	66·6	72	75
Energy practically available in kilos. for total weight, supposing that work is equal to 10 per cent. of stored heat ...	1,785	—	—	—	—

From the above data it will be seen that a kilogramme of total weight (water and reservoir) heated to an initial temperature of 250°, stores a quantity of work equal to $66\cdot6 \times 425 \times 0\cdot10 = 2\cdot830$ kilogrammetres.

The theoretical work stored in a kilogramme of total weight (reservoir and air) is equal to $\frac{20\cdot765}{12+1} = 1\cdot597$ kilogrammetres only. Hot water can store more work than compressed air, and the work thus stored by a unit of weight increases at first with temperature, then remains stationary, and finally decreases. But the special point to notice is that this way of storing energy, though possessing good qualities, is in certain respects the same as compressed air; for instance, very limited in power.

Lastly, it should be noticed that whereas superheated water can be produced from a simple boiler, compressed or liquefied gases require special machines, which are very dear and complicated.

Use of Chemical Actions; Combustion.—The chemical action which can produce, with equal weight, the most work is combustion. The calorific power of certain combustibles is very great; 8,000 calories for wood and coke, from 8,000 to 9,000 calories for oil, from 10,000 for petrol, and from 11,700 for acetylene; lastly, a cubic metre of gas gives in burning 5,500 calories. Coal possesses a very great specific power, for in burning, 1 kilogramme of coal can produce a number of calories which, being entirely changed in working, would at length be theoretically raised to 3,400 kilometres. Also, in spite of the considerable loss of work which is involved in its employment, coal must be considered as being destined to be used in everything worked by motor force; moreover, contrary to petrol, its production is unlimited, whereas that of petroleum is very limited and is only to be found in certain parts of the globe. The calorific work of coal in mechanical work is to impart the disengaged heat caused by its combustion to an intermediary body alternately heated and cooled.

Work of the Boiler.—The best boiler is the tubular, which possesses the great qualities of being light and economical. MM. Noze and Geoffroy have made experiments on a boiler of the locomotive type, the tubular part of which was divided into a certain number of compartments and which give the following results. The proofs mentioned in this table took place in a boiler, half of the tubes of which had been stopped up by stoppers placed by the side of the boiler, so as the total production of steam per hour was the same as in the original boiler. The boiler produced 6·93 kilogrammes of steam per kilogramme of coal, whilst the production of steam per square metre attained the large total of 116 kilos. per hour, corresponding to the work of 10 horses:—

No. of Compartment.	A.	B.	C.	D.	E.	F.	G.	H.
1	6·37	6·37	1,390	1,390	218·0	218	3·61	3·61
2	8·31	14·68	852	2,242	102·0	152	2·21	5·82
3	8·31	23·00	431	2,673	52·0	116	1·12	6·93
4	8·31	31·30	263	2,936	31·7	94	0·68	7·63
5	8·31	39·60	193	3,129	23·2	79	0·50	8·13

A is the surface of the considered compartment.
B, the total surface of *n* 1st compartment.
C, the weight of steam produced in an hour by the considered compartment.
D, total weight of steam produced by the *n* 1st compartment.
E, the weight of steam produced in an hour on a square metre, on the surface of the considered compartment.
F, the total weight of steam produced in an hour on a similar square metre by the *n* 1st compartment.
G, the weight of steam produced by 1 kilo. of coal in the considered compartment.
H, the weight of steam similarly produced by 1 kilo. of coal by the *n* 1st compartment.

A locomotive boiler, capable of resisting the strongest pressure used, weighs from 100 to 120 kilos. per 1 sq. metre of heating surface.

Another experiment made by M. Henry on a locomotive boiler, the tubes of which were 3 metres long, with an interior diameter of 46 millimetres, and an exterior diameter of 50 millimetres, gave the following results:—

Pressure in Millimetres of Water.

—	Ordinary Grate.			Tembrinck Grate.		
	25	45	75	25	45	75
Coal burnt per hour in kilos.	466	650	863	446	607	780
Water evaporated per hour in kilos.	3,667	4,907	6,136	3,844	5,150	6,341
Co-efficient of economy ...	7·87	7·55	7·11	8·62	8·48	8·18

M. Baudry has also made similar experiments on an engine provided with ribbed tubes, 2 metres long and 50 millimetres in diameter. The total number of tubes was 185; their interior diameter 46 millimetres, their interior surface was 52·50 sq. m., and the whole total surface 93 sq. metres; the grate area, provided with a Tembrinck boiler, was 14·2 m. The weight of this boiler was much reduced, as the cylindrical part was only 2 metres long. The weight of the water did not exceed 400 kilos., however the force and economy of this boiler was greater than the boiler 3 metres long. The results obtained are given in the following table:—

Pressure in Millimetres of Water.

—	25	45	75	100	120
Coal burnt per hour in kilos.	428	565	715	828	907
Water evaporated per hour in kilos.	4,019	5,254	6,585	7,535	8,181
Co-efficient of economy	9·39	9·30	9·21	9·10	9·02

A tube with ribs 2 metres long is more economical and has more heating power than an ordinary tube of the same diameter but twice as long. Tubular boilers are not safe for automobile carriages; they enclose a great quantity of water at a high temperature. The boiler being able to contain so much water saves a great amount of work caused by refilling, but, on the other hand, it may become very dangerous in the event of an explosion. On railways, where the inspection of boilers is perfect and they are worked by thoroughly competent men, the danger is almost *nil*, but this state of affairs does not obtain with automobile carriages.

Acetylene.—The Explosives Department of the Home Office has recently had under consideration the question of the restrictions to be applied to the manufacture and keeping of acetylene gas, and has conducted various experiments with the object of gaining information on this matter. The results show conclusively that acetylene gas *per se*, when under a pressure of something less than two atmospheres, is violently explosive; whereas at a pressure of less than $1\frac{1}{2}$ atmospheres it appears to be reasonably free from liability to explosion, provided it is not admixed with oxygen or atmospheric air. For commercial and practical purposes it is considered sufficient to allow a pressure of 20 in. of water above that of the atmosphere (*i.e.*, roughly about $1\frac{1}{20}$ atmospheres), and it is accordingly proposed to draw the safety line at this point, and to declare acetylene when subject to a higher pressure to be an "explosive" within the meaning of the Explosives Act, 1875. In France and Germany, the authorities have fixed the limit of danger at $1\frac{1}{2}$ and $1\frac{1}{10}$ atmospheres respectively, and have imposed prohibitions or restrictions on the keeping or manufacture of the gas when it is at a higher pressure.

THE DAIMLER MOTOR COMPANY (LIMITED).

BALANCE SHEET.

MAY 31ST, 1897.

Submitted at the Second Ordinary General Meeting, held at the Holborn Restaurant, Thursday, October 14th, 1897.

In presenting the report the directors, in congratulating the shareholders upon the satisfactory results of the first year's working of the business, state that in this period the Company has had to establish, organise, equip, and partly build its works, and also prepare designs, patterns, and tools for manufacture, work which must in any case entail considerable expense and time, but especially difficult when embarking upon an entirely new industry such as the business of the Company is.

They further report that the factory is now fully engaged in the regular output of motor and motor-carriages, the demand for which appears to be steadily increasing.

Although the very satisfactory and substantial balance of £9,175 17*s.* 6*d.* stands to the credit of the Profit and Loss Account on the first year's working, equivalent to nearly 10 per cent. on the capital of the Company, the directors do not recommend the payment of a dividend, as they have found it necessary to utilise this balance in the laying down of additional plant to meet the orders in hand.

Oil as Locomotive Fuel.—The fastest and longest run of a train hauled by an oil-fired engine is, says *The Engineer*, that of the Cromer express, on the Great Eastern Railway. Leaving Liverpool Street terminus at 1.30 p.m., this train arrives at Cromer—138 miles' distance—at 4.25 p.m., with but one stop at North Walsham, eight miles from Cromer, where it is due at 4.10. This gives a run of 130 miles in 160 minutes, or an average rate of 48·75 miles per hour. The train is regularly worked by the single-driver express engine of Mr. Holland's standard design, and fired on his oil-fuel system, and no similar fast train in the world is worked with such ease to the firemen.

NOTES OF THE MONTH.

Lord Carnarvon has purchased a motor-car.

Mr. D. Albone, of the Ivel Hotel, Biggleswade, stores petrol for automobilists, and, being a cycle manufacturer, can undertake repairs, &c.

Mr. Jas. Roots, the well-known maker of various types of automotors, is contributing an excellent series of articles on gas and oil engines to *The Engineer.*

The first electric motor-cab wedding took place on September 16th last at Brixton Church. Needless to say the bride and bridegroom attracted more than the usual attention.

Mr. A. Valentine (Student I.C.E.), of Croxton House, Leamington, has been appointed agent for the Arnold motor in that district. He stores petrol for the use of automobilists.

Owing to the failure of a scheme for a light railway between Lincoln and Brigg, a proposal is now being brought forward to improve the communication between these places by the formation of a motor-car company.

Country visitors to London with motor-carriages will be glad to know that good accommodation, if not for man and beast, at any rate for motors, can be obtained at Coulson's Livery Stables, Endell Street, Long Acre.

We understand that the cycle show to be held in Liverpool on January 11th next year will also comprise an exhibition of motor-carriages. Intending exhibitors should apply to Mr. Thos. Price, 77a, Lord Street, Liverpool.

The total "paid up" capital invested in British railways at the close of last year was 1029·5 millions, of which more than 10 per cent. is simply nominal, consisting of additions made in the conversion, consolidation, or division of stocks.

The United States naval officials are about to undertake a series of experiments to ascertain whether petroleum fuel, which would occupy less space than coal, can be satisfactorily adapted for use in torpedo-boats, and one of the torpedo-boats now building at the Herreshoff yards will be used for conducting a series of experiments with oil-burning apparatus. These experiments will be carried out at the Newport torpedo station.

L'Electricien mentions an instance of great presence of mind on the part of a Frenchman travelling in a New York electric cab. The cab suddenly stopped, and one of the occupants—a cool-headed engineer—investigated the cause and found that the fuse had blown. It was the work of an instant to take a tablet of chocolate out of his pocket, remove the tinfoil in which it was wrapped and connect it in place of the fuse, so as to allow the cab to proceed gaily on its way again. We shall now expect to see automatic sweetmeat distributors added to the comforts of our electric cabs.

The beautiful "Rougemont" carriage that has been specially constructed for Miss Minnie Palmer by the Daimler Motor Company was delivered to her in Aberdeen last week. It is made to carry six persons, and its speed can be regulated to four, eight, or 16 miles an hour. Its first appearance in Aberdeen created somewhat of a sensation, where motors were unknown. Miss Palmer has already started on her travels in her new acquisition, her first journey being to Dundee, where she has been appearing in *The School Girl.* Miss Palmer's example should be speedily followed by other members of *the* profession, as packed audiences have been the result so far, due in a measure, no doubt, to the bold advertisement obtained through the motor-carriage.

"After waiting nearly a year," says the editor of the *Cyclist*, "we have at last obtained delivery of our own particular autocar, and on Thursday, Friday, and Saturday we travelled considerably over 100 miles upon it. Although we had only once previously practically handled a car, we drove it from Northampton on Thursday, and on Friday took it through all the traffic of the Birmingham streets, which will show how soon the management of a good car can be mastered. It is driven by a Daimler motor, will carry five, steers like a bicycle on a good road, and swings along at an average 12-mile pace splendidly. If any of our readers are fancying autocaring, we can recommend the pastime as an exhilarating one, and we are also in a position to state that these vehicles have now reached a thoroughly satisfactory and practical stage, and no one need have the least hesitation in placing orders."

Drivers of road locomotives in Kent had better avoid Sandwich, if possible, as in that decaying town there is a deal of decayed property, and the Mayor is afraid it might fall down and hurt some one if a locomotive passed through the streets. While presiding in his awful magisterial capacity as the local "Beak," he asked the local bobby if he had a copy of the bye-law regulating the passage of locomotives through the town. The policeman said he had not, and his worship said he should be furnished with a copy. The bye-law said that the rate of speed while passing through the town should not be more than two miles an hour; but there had been frequent complaints that the rate was greatly exceeded. A good deal of damage to property was likely to be done by these heavy machines passing through the streets at full speed, and he hoped the police would bring any offenders before the Court. Needless to say, the policeman said that he would give instructions to that effect.

Speaking of the recent French heavy-weight trials the *Electrical Review* says, at the conclusion of an article :—"While steam is so decidedly best for heavy traffic, petroleum is, at any rate, serviceable for loads up to one ton. Electricity is not named. It appears that the steam and petroleum cars are dear, 18,000 francs being quoted for a petroleum omnibus, and 22,000 francs for a steam car, figures a little outside the range of ordinary transport concerns. A four-horse coach will be horsed for about £160, or 4,000 francs, but one team of horses will not run it all day; so that a four-horse coach represents probably nearly 12,000 francs of capital for a day's work. Still, the mechanical omnibus seems dear, and must be reduced or shown to be very economical in order to make its way. Since the foregoing was written, the electric cab has been placed on the streets in London, and it seems to run very well. But London streets are smooth, and if accumulators cannot work satisfactorily on a London cab they can work nowhere on a moving vehicle. The London experiment should afford very valuable experience for improving the accumulator."

Professor R. C. Carpenter, of the Cornell University, has been conducting an elaborate set of experiments on bicycle friction which have led him to the conclusion that no form of gearing can possibly equal the best chain for efficiency and durability. With such the frictional loss has been found to be between $\frac{1}{2}$ and $\frac{3}{4}$ per cent. of the total power transmitted, this result being obtained with a chain which had previously been ridden more than 2,000 miles with a rider weighing about 14 stone. With some other chains less well constructed, a greater loss has been found, the friction lying generally between 2 and 5 per cent.; the maximum shown even by an old chain which did not fit its sprocket properly was under 10 per cent. No bevel gears yet constructed give as good results as these, and Professor Carpenter concludes that with even the best bevel-geared bicycles the loss must be four times as much as with an ordinary chain, and six times as much as with the best chain. Moreover, as has been previously pointed out, gear wheels to work well must be in very accurate adjustment with each other, whilst with a chain no such careful fitting is required.

MR. F. T. BIDLAKE, the well-known tricyclist, writes in the current *C. T. C. Monthly Gazette*:—"Until recently I shared what I believed to be the very general opinion that a motor tricycle is a costly plaything of a most unreliable nature, tricky to manage and apt to suffer serious derangement of its working parts. An extended trial of one has dispelled this illusion completely. I do not mean to say that it is cheap, or may be carelessly handled with impunity, but when you sit still on a machine and coast, uphill as well as down, and can keep up 20 genuine, not policemen's, miles an hour on the level, you cannot write the thing down a fad. I learned the meaning of the taps in half a mile, and the fascination of manipulating them haunts me now, though I have had to return the machine, and the new toy pleased me well enough to urge me to do 190 miles in one day on it, and I only stopped then for a fault in the machine independent of its motor nature. Although you lose the independence of a cycle, you gain in being heedless of the question of fatigue. Your motor can do its hundredth mile as easily as its tenth, and the last yards of a climb are run at a uniformly tiring pace, fatiguing to the muscles of the man motor who essays to keep with you."

Wind Motors.—At a special meeting of the Town Council of Lymington recently Mr. Rollason attended with a model of his wind motor—the latest kind of improved windmills—and explained its working in detail. He proposes to erect one at Waterford, together with a huge storage tank, at a cost of £454, and maintain the same for 12 months. In reply to questions, Mr. Rollason said his guarantee was that the motor would do the work if there was sufficient breeze, but not otherwise. It was agreed to obtain further data as to wind power in the district before proceeding further with the subject. Before separating, the Mayor, in the name of the Council, heartily thanked Mr. Rollason for attending and for the valuable information he had given them.

Not Abreast of the Times.—The City Companies, as befits their mediæval origin, are not, as a rule, promoters or encouragers of their various "Crafts" and "Mysteries." We are not aware that the Grocers' Company have done anything to prevent, say, adulteration, nor do we remember any sartorial improvement emanating from the Merchant Taylors; while the Spectacle Makers have certainly done nothing to encourage optical research. Hence we are not surprised to learn that the Coach Makers are not encouragers of the "Arte or Mysterie" of motor-car manufacture, probably because this Company also includes the Coach Harness Makers. Of course a City Company must, however, do something to justify its existence in the eyes of a public which, urged on thereto by wicked Radical newspapers, is always asking *Cui bono?* And so the Coach Makers have offered prizes, amounting to the princely sum of about £50, for the best designs in carriages. There are five competitions of various kinds, but we see no reference to motor-carriages, and good designs of the latter are badly wanted just now, and we can only express our surprise and regret that the Coach Makers' Company should be so blinded by and guided by its mediæval traditions as to exclude motor-carriages in the 1898 competitions. However, our French friends will no doubt assist the "trade" in this.

CONTINENTAL NOTES.

Two of the latest disciples of automobilism are M. Edmond Blanc, of Paris, and the King of Siam.

IT is proposed to establish a permanent exhibition of automotor vehicles and accessories in Paris.

WE understand that M. Bollée is busy upon a new design of automotor of which great things are expected.

OWING to the new French regulations automobilists have now to carry about a large heavy book containing the law on the subject.

THE latest Pennington tricycle is *said* to give off 12 H.P., and its weight is also *said* to be 150 kilos.—at least *Les Sports* says so.

As one result of Les Poids Lourds, a French Omnibus Company is adopting the De Dion omnibus for certain lines in the south-western district of Paris.

IN consequence of some unfavourable criticisms that have appeared in the French Press concerning the London electric cabs, the Company concerned has dispatched one to Paris for inspection.

NOT content with its achievements, the Automobile Club is about to establish a line of automotor mail coaches in Paris available for excursion parties. These will start each day from the Place de l'Opera.

BERLIN is at length awakening to the possibilities of automobilism, and an exhibition of automotors will be held in that city from October 25th to November 25th, under the auspices of the Deutsches Export Musterlager.

AFTER the heavy-weight trials M. Scotte proceeded with his motor and trailer to Luxembourg, where he had a most gratifying reception. He has returned to Paris with his vehicles, and the French Customs have demanded 6,000 francs as duty.

THE French Minister of Marine invited essays and designs for submarine boats this year; 47 authors responded, six sent in complete designs. Three types are considered to be feasible. One is worked by electricity, another by automatic machinery, and the other by petrol.

IN Berlin the fire brigade employs steam tricycles. These are always kept ready for a start, and on a call being received two firemen proceed at once to render preliminary assistance by clearing the way, &c. When will the London County Council drop its present expensive system of horse traction?

THE Automobile Club of Paris has already decided upon its programme for 1898. It will comprise an exhibition of vehicles, and will last throughout June. There will be four sections, consisting of automotor vehicles which have given proof of their practical efficiency, industries connected with automobilism, motors and vehicles adapted for automotors. On July 5th, and on the following days, there will be a race from Paris to Amsterdam and back, a distance of 868 miles, and a body of members will proceed to survey the route to St. Petersburg for the Paris-Petersburg race to take place in 1899.

MAKING MANHOLE JOINTS IN BOILERS.

As steam is unquestionably destined to be the motive power for vehicles intended for heavy traction on roads, and as this steam must necessarily be of high pressure, boilermakers and others will do well to pay particular attention to such details as making joints in doors, handholes, &c. The importance of

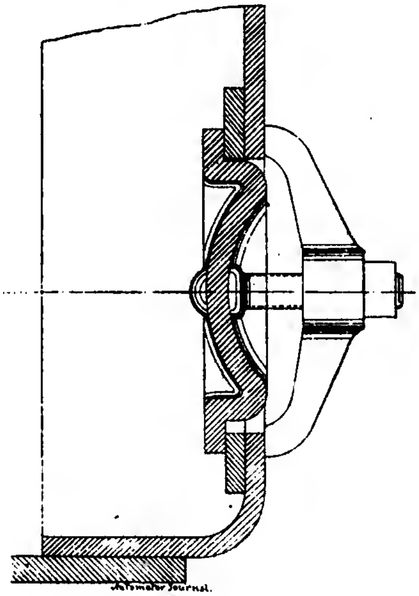

Fig 1

accurate fitting can hardly be over-estimated, as the consequences attendant upon a sudden eruption of steam and water in a street would be very serious, involving possible loss of life and damage to property. The blowing out of the packing used in making manhole joints is always a likely contingency unless the very greatest care is exercised. As showing the importance

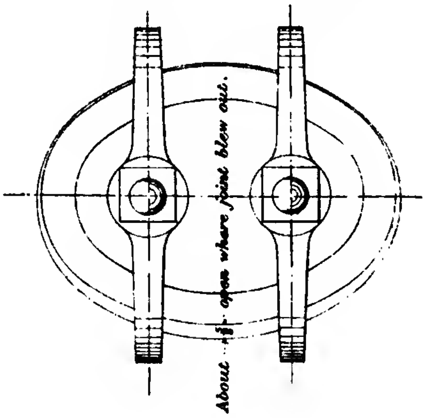

Fig. 2.

of this we give an account of an accident of this nature which occurred on board the steamship "Strathclyde." This vessel is a screw steamer of 3,314 tons. She was outward bound from the Tyne in ballast for Montreal when the explosion occurred.

A portion of the material of which the joint of the door of the forward lower manhole of the port boiler was made was blown out from the lower edge of the door, where indicated in the sketches (*see* Figs. 1 and 2), and the contents of the boiler were discharged with considerable force, the pressure of steam on the boiler at the time being from 140 lbs. to 150 lbs. per square inch. The second engineer, who has been three years on this steamer, stated that the first intimation he had of the explosion was by hearing a "shout" from the fireman, whom he met coming from the stokehold, and who told him that one of the forward doors had blown out. He immediately pulled the fireman's trousers off, and had him removed to the poop, where his legs were dressed preparatory to his removal to the Shields Infirmary. After he had eased the starboard, and the chief engineer the port safety valves, attempts were made to get into the stokehold to draw the fires, but owing to the presence of steam and water, the ship rolling and the *debris* floating about in the stokehold, this was not accomplished for some hours. The second engineer also stated that the appearance of the joint before the door was taken off showed that for 4 or 5 inches at the bottom it had been blown clean out. Previous to the blowing out of the joint he had seen no leakage from any of the doors, and until this casualty no trouble had been experienced with the doors, which had always been jointed with flat asbestos rings made to order, excepting on one passage from Hamburg to the Tyne, when several of the joints had been made with Tuck's packing. From the statement of the chief engineer, it appears that a requisition had been made for asbestos tape jointing material, but steam having been required before the demand had been complied with, the joint was made with $\frac{3}{4}$-inch round packing. The spigot of the door in the direction of the major axis was less than the manhole by $\frac{5}{16}$-inch and in the direction of the minor axis by $\frac{3}{8}$-inch.

In his remarks on the explosion, Mr. P. Samson, the Engineer-in-Chief of the Marine Department of the Board of Trade, says:—

"This explosion affords another illustration of the danger which may arise from the use of badly-fitting manhole doors, especially when the joints are made with packing of unsuitable section, and when sufficient care is not taken to ensure that the doors are placed centrally in the manholes. It appears that it has been the usual practice on this vessel to use flat asbestos rings for the joints of the manhole doors, and no trouble was experienced with that description of joint, but it seems the joint of the door in question was made with $\frac{3}{4}$-inch round packing in this instance, in consequence of the supply of flat asbestos rings being exhausted, with the result that the explosion followed shortly afterwards, and, unfortunately, injured one of the firemen."

ALLOYS AND BRONZES.

THE addition of $\frac{1}{4}$ to 1 % of aluminium to the ordinary brass and bronze mixtures effects a great improvement. The metal runs better and is more durable and tough. A higher percentage of aluminium will produce brittleness.

Aluminium Bronze consists of copper 90 %, aluminium 10 %; or copper 95 %, aluminium 5 %. The former alloy has a tensile strength of 80,000 lbs. It is largely used for bearings, gearing, chain belting, and for all purposes where great strength and toughness are required.

Silicon Bronze—Copper 95 %, silicon 5 %—is, as regards strength, equal to aluminium bronze, but does not resist corrosion so well; it, however, casts better.

Manganese Bronze, as now made, consists of—

	%
Copper	53
Zinc	42
Manganse	3·75
Aluminium	1·25
	100·00

This is perhaps the best material to employ for heavy or light gearing wheels.

Imitation German Silver.—

	%
Copper	67·25
Manganese	18·50
Zinc	13·00
Aluminium	1·25
	100·00

This takes a good polish, and is besides very strong. May be usefully employed for motor-car purposes.

Aluminium Solder.—

	%
Aluminium	2·38
Zinc	26·19
Tin	71·19
Phosphorus	0·24
	100·00

Another solder for aluminium is known as Green's; it is stated to be composed of—

	%
Zinc	50·03
Tin	47·99
Aluminium	1·76
Phosphorus	0·22
	100·00

No flux is required, but the faces of the joint are cleaned and coated with solder, and a hot bit is used to make the joint.

Mr. John Philipson on Coach-building and Automotors.—At the Durham College of Science, Newcastle, on September 29th, Mr. Henderson, president of the Institute of Carriage Manufacturers, presented the prizes to the successful students in the carriage building classes last session. The chair was occupied by Mr. John Philipson. The Chairman, in the course of his opening speech, said:—I am pleased to notice that science subjects are engaging attention, and I should like to impress upon young coachmakers the importance at the present time of devoting some attention to applied mechanics, and this for two reasons. I need not remind you that the future success or failure of many industries will be in proportion to the employment of labour-saving tools. Now, some of the best labour-saving tools in use at the present time have been invented by workmen, and this fact is not difficult to understand, because those men have had a knowledge of applied mechanics, and they knew precisely what conditions would have to be fulfilled by the tool in working. The second reason is, that in a short time motor-carriage construction will form a department in many carriage factories, and the man with a knowledge of mechanics and machine construction will stand in a vastly more favourable position than he who is ignorant of such matters. I say that I believe the construction of self-propelled carriages will ultimately form a department of our business, because I feel assured if the motor-car has to come (and there cannot now be any doubt about its coming) coachmakers cannot afford to rest on their oars and allow the new industry to be monopolised by others outside of the trade. The motor-car is yet far from perfection, but it would be idle to shut our eyes to the fact that it must eventually play an important part in our methods of travel and transit, and in this connection we may reasonably congratulate ourselves that the birthplace of the locomotive has not been behindhand. The long series of experiments which have been carried out by my firm and our friends, Messrs. Toward, have convinced me that for rural districts, where there is no electrical supply—steam will play the most important part as the motor power chiefly on account of its simplicity and its reliability.

ELECTRIC CABS IN PARIS.

The Paris correspondent of the *Pall Mall Gazette*, which paper, by the way, is evincing an intelligent appreciation of automobilism rather rare in the daily Press, sends an account of an interview he has had with M. Bixio, who is President of the Compagnie Générale des Voitures à Paris, and who has sent an engineer to report upon the London cabs.

Said the *P.M.G.* man: "And does he speak favourably of the London cab?"

"Not exactly; but it is just what I expected. The fact is, that although there are several motor-cabs running in London, the results are not very satisfactory, English engineers being hampered by exactly the same difficulties as ourselves. In my opinion, it is useless to put electric cabs in circulation until these difficulties have been overcome."

"Then when do you expect to be able to give them a trial in Paris?"

"Ah! that is absolutely impossible for me to tell you. I am considering new ideas and receiving new specifications almost every week, and I carefully examine them all. Some of them are quite worthless; others contain certain improvements, and I have no doubt in the end we shall find a motor-car that will give us more practical results than we have yet obtained. At the present time I am expecting a motor-car from Berlin, one from London, and another from New York. You see, we are not letting the grass grow under our feet."

I imagined that the difficulties of which M. Bixio spoke were the old difficulties of the motor and the accumulators. I asked him if this were the case.

"Yes," he said, "you are right, and it is especially the accumulators that are troubling us. The motor only presents difficulties of quite minor importance. The whole question turns on the weight and the power of the accumulators. An ordinary cab covers about 60 miles a day, and in order to be ready for emergencies the accumulators ought to have a driving power of, say, 80 miles. Of course, there is the alternative of re-charging in the middle of the day, and in this case 40-mile accumulators would answer the purpose. But this would lose the cabman's time, and would also entail extra expense at the charging stations. What we are trying to find is an accumulator that will carry a cab about 80 miles. Now, I am told that the accumulator in use in London is 10 years old; the best we have in Paris is only five years old."

"Do you consider that petroleum or electric automobile carriages will be in use in Paris in the future?"

"Oh, the petroleum car has no chance at all. As soon as we get the electric car ready, the petroleum automobile will be seen no more. For several reasons the latter cannot compete with the former, principally because it is not strong enough—that is to say, it cannot be relied upon to ascend an incline, such as the Rue des Martyrs or the Rue Lafayette. I quite admit that at present there is an enormous demand for the petroleum autocar, and the manufacturers are, I am told, asking for from 15 to 18 months for the execution of an order. But it is mostly the wealthy classes and amateurs who are using it. They obtain amusement from it just as a child is amused by a new toy.

"But I am of opinion," concluded M. Bixio, "that neither the electric nor the petroleum car will ever come into universal use. Automobilism is only likely to replace horses in public conveyances and in the case of delivery carts and wagons. The wealthy classes will always keep to their horses. A wealthy man will never be so proud of his automobile as he is of his well-groomed thoroughbreds."

The fourth Dublin Cycle, Motor-Car, and Inventions Exhibition is to be held from January 15th to the 22nd, 1898, in the grounds of the Royal Dublin Society.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to The Editor of "The Automotor and Horseless Vehicle Journal," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. King and Co., Limited, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., *including prepaid postage to any part of the world. Single copy* 7d., *post free.*

Cheques and Post Office Orders should be made payable to F. King and Co., Limited, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

SPECIAL NOTICE.

The Automotor and Horseless Vehicle Journal *can be obtained from all* Messrs. W. H. Smith and Son's *bookstalls, and the following Agents:*—

London: Pottle and Sons, 14 and 15, Royal Exchange, E.C.
Wholesale: Brett and Co., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. McCann, 37, Union Street.
Manchester: John Heywood, Deansgate.
Newcastle-on-Tyne: C. C. Ross, 35, Side.
Paris: Homère Moreau, 97, Rue Nollet.
Victoria (Australia): Phillips, Ormonde, and Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. *for* 12 *months' subscription, post free (or at the rate of* 7d. *per copy).*

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

OCTOBER 15th, 1897.

ANSWERS TO CORRESPONDENTS.

A. J. Ashmore (Rowney Green, Alvechurch). — We have returned your drawings and stamps. We could not say whether the invention is novel or worth patenting. Your best course is to consult a patent agent. You might communicate your ideas to Messrs. Haldan and Co., 18, Buckingham Street, Strand, London.

H. H. (York).—We cannot recommend as an investment. See the back numbers of our Journal, in which 20 or 30 references are made to this affair.

W. E. H. (Altrincham).—(*a*) We regret it is impossible to supply you with No. 1 except in volume form, the price of which is one guinea net. (*b*) We thank you for all your suggestions *re* 1898 Handbook. The majority of them have already been embodied and are in type for the forthcoming issue. You will find that the new book will more than satisfy the requirements you mention.

J. K. (Forres, N.B.).—The address of the Clayton Company is New York. They are a very big Company, and a letter addressed simply New York is sufficient.

B. ROBERTS (Hyde Park).—(a) No. 7 is a Daimler motor; the address of the Company is 219, Shaftesbury Avenue, W.C. No. 17 is a Benz motor; the address in Germany is Messrs. Benz and Co., Mannheim. For England you had better apply to Arnold's Motor-Carriage Company, East Peckham, Kent. (b) At present the £1 shares stand at $\frac{7}{8}$ to $1\frac{1}{16}$.

DR. TURNER.—You will find considerable information on the Serpollet system in our back numbers. By reference to the Index which is issued with this number you will find the pages. You might also apply to Mr. E. Shrapnell Smith, Royal Institution, Colquitt Street, Liverpool, who possibly might send you a copy of the Committee's report on this system, which has been issued. A motor-vehicle has been completed on this system in England, and we understand it will not be very long before building motor-vehicles on the Serpollet system will be in full swing in this country.

CLUBS.—(a) We cannot advise you upon the first point. (b) We are not connected with either of the proposed clubs. For any information you require from either of them it will be necessary to write to either Mr. Harrington Moore, 4, Whitehall Court, London, or Mr. Andrew W. Barr, 30, Moorgate Street, London, E.C.

J. B. (Liverpool).—The advertiser had an enormous number of answers in reply to his advertisement, and we believe he is still considering the various designs sent in. We hope later on to receive particulars of his decision and, if possible, shall publish the selected design.

E. J. W. G. (Chipping Norton).—We have no power to issue a permit as suggested, but you may rely upon being received with every courtesy if you mention the name of our JOURNAL.

LEON GROSSE (Aix-les Bains).—(a) We have sent you subscription form as desired. (b) A communication to any of the following should procure you what you want:—Daimler Motor Company, Coventry; Roots and Venables, 100, Westminster Bridge Road, London, S.E.; London Electrical Cab Company, Juxon Street, Lambeth.

W. K. (Ayr)—Your best plan would have been to join the rest of the shareholders originally. We cannot advise you upon your present position, and suggest your communicating with the solicitors who have the matter in hand.

THE GREAT HORSELESS CARRIAGE COMPANY AND THE BRITISH MOTOR SYNDICATE.

THE idea of buying up all the patents relating to a new and promising industry could only emanate from the brain of a clever man; equally so was the idea of forming subsidiary companies to work, more or less completely, some or all of the said patents. The idea, however, of investing in the latter companies could only emanate from the brains of members of the great British public who, as a rule, are *not* clever; indeed, a great philosopher has said that the majority are—well, not exactly very wise persons. We should prefer to put it this way—those who formed the British Motor Syndicate had the brains, while those who subscribed to the Great Horseless Carriage Company, which was formed to work the "valuable patents" owned by the former, had the money but no—or perhaps not much to speak of—brains. An exchange has been made which is apparently agreeable to the members of the Syndicate, but slightly less so to the shareholders of the Great Horseless Carriage Company, who find their £10 shares worth only a few shillings apiece; little or no business being done, general bad management and inefficiency at headquarters, with every prospect of litigation, culminating in reconstruction, or something worse. If we cannot congratulate the shareholders on possessing a remunerative business, we certainly can upon the "vast practical experience" that they are individually acquiring, and which they will no doubt increase, in the art of commercial manipulation. That many of the patents bought up by the Syndicate are valuable cannot be denied, but whether many of them will be worth renewing when they run out is doubtful. On the other hand, the Syndicate owns much patented rubbish. As an example of this we may mention Patent 15,947 of 1893, "For sounding a whistle on an explosion engine by causing the products of combustion to be exhausted through the said whistle"—about as useful an invention as that of a whistle made of sugar candy. It was to work these and other "valuable patents" that the Great Horseless Carriage Company was formed in May, 1896, with a capital of £750,000.

It would seem from the prospectus that the objects of the Company were "to purchase a license to use all or any of the applications for patents, patent rights, or letters patent of or belonging at the present time to the British Motor Syndicate (Limited), so far as such application, patent rights, or letters patent relate to carriages, vans, carts, tramcars, and all other vehicles excepting cycles, bicycles, and tricycles." A committee of the dissatisfied shareholders in the Great Horseless Carriage Company complain that "since the flotation of this Company the British Motor Syndicate have gone on improving the different inventions and buying newer and later patents, the benefit of which they withhold from us, while this Company have bought none, and in a business like this, where its very existence depends upon it being up to date, it is clear that owing to this Company having only bought a partial and non-exclusive interest in the patents owned by the British Motor Syndicate up to but not since May, 1896, it is being altogether left out in the cold, and that in a short time there is every possibility of its having merely old and out of date models to work upon."

We should say that this is very probable. The committee continue:—"In addition to this all-important error of judgment in the formation of this Company, it appears that the directorate contained several members of the board of the Daimler Company. It is, therefore, not surprising to find that this Company paid for its share of the buildings at Coventry more than the whole of such buildings cost when originally acquired by the Daimler Company. Further, that the Daimler motors themselves are being sold to us at immense prices, while our works are employed in making the carriage frames merely under the Daimler directors' instructions. Further, the British Motor Syndicate not having granted us exclusive licenses, has the right to run against us in connection with all its patents, and has also been granting, and continues to grant licenses under the patents in which we are interested, and their newer patents above referred to, to numbers of companies and firms, thereby creating for us business rivals whom we are powerless to interfere with. The Company, therefore, appears to be at the mercy of two enemies—viz., the British Motor Syndicate on the one hand, who claim that they own practically everything, and keep acquiring fresh patents with a view of shutting out everyone else (ourselves included), and the Daimler Company on the other hand, who are living freely upon us. The result is shown pretty clearly by the value of the shares. The £1 shares of the British Motor Syndicate, with a capital of £1,000,000, are quoted at par, while this Company's £10 shares are practically valueless."

The committee seek the co-operation of their fellow shareholders in the direction of a reorganisation, and have instructed a firm of solicitors to investigate the matters complained of. The committee announce their intention "to endeavour, in conjunction with our directors, if they are willing (or, if not, then without them) to obtain from the British Motor Syndicate fair proposals for this Company's future, either by amalgamation on fair terms or otherwise, but to submit such proposals first to the full committee, and afterwards to a general meeting for full consideration. Failing this to requisition for a general meeting to remove any directors who may oppose us, and (if so advised) to take proceedings against the British Motor Syndicate, &c., for return of the purchase price and damages."

To this formidable indictment the directors of the Great Horseless Carriage Company reply also in a circular to the shareholders that the aforesaid statements are misleading and in many cases untrue. They also report that the Company is making steady progress. According to an interview with Mr. H. J. Lawson, published by our contemporary, *The Road*, that gentleman attributes the evil state of the Great Horseless Carriage Company to lack of knowledge on the part of the directors and serious mistakes in the management. Yet in the same breath he says it would have been difficult to come across men more suitable for directors. We do not think so. The Board included a respectable Peer as chairman—who necessarily could have no technical knowledge, and, besides, peers and other noblemen are as a rule entirely out of place on industrial directorates. The other gentlemen composing the Board undoubtedly knew a good deal individually about automobilism although they are not engineers, but we are not aware that they had any great reputation for the successful conduct of large business operations such as are involved in the use of nearly three-quarters of a million of money. And of these directors the more competent were aliens and resided abroad, while those who represented the commercial element were hopelessly divided in their policy. Under these circumstances it is not surprising that one manager followed another into seclusion.

If, again, we consider how restricted are the operations of the Company, and how these are shared by other Companies, it will be seen that there can hardly be sufficient business to earn a dividend upon such a large capital. The Great Horseless Carriage Company is practically restricted to making horseless vehicles of one type, viz., those operated by light oil-motors, although we gather that they are to manufacture the vehicles required by the London Electrical Cab Company. As far as we can see, the position appears to be this—the Great Horseless Carriage Company has acted as a kind of wet-nurse to both the British Motor Syndicate and the Daimler Company. It has supplied the financial pabulum to both, and now finds itself getting more and more flaccid while these other Companies are waxing fat. According to the statements made in *The Road*, it appears that the total capital was £750,000, of which £600,000 has been issued, leaving an uncalled balance of £150,000. Of this £600,000, the public contributed £300,000, and of this huge sum, viz., £600,000, only £120,000 was working capital, of which £70,000 has been spent, leaving but £50,000 to carry on the business with, or the actual cash in hand is but one-fifteenth of the original nominal capital. The Great Horseless Carriage Company now finds itself in the position of having depleted coffers and torn by internal dissension. The question is—What is the best course to pursue? We suggest that a valuation of the plant, patents—especially the patents—should be made, and their value be severely written down, so as to disclose the true position of affairs. The legal rights of the Company as against the British Motor Syndicate should be clearly ascertained, and a policy either of conciliation or litigation adopted accordingly. The directorate should be entirely recast, and, as far as possible, all interests in other motor concerns should be eliminated. A definite policy of motor-carriage building should be decided upon, and the leakage of money for so-called experiments should be summarily stopped.

It strikes us as a curious thing that a Company which owns so many valuable patents should yet be obliged to conduct experiments; this fact alone shows the valueless nature of these so-called "master patents." We are afraid, however, that the Great Horseless Carriage Company has made a bad bargain, and for its present position its directors are morally if not legally responsible. But if the shareholders of the Company agree to the propositions set forth in the circular emanating from "A shareholder," they should bear in mind that by so doing they waive their legal rights to the recovery of their money subscribed for shares under the original prospectus.

This circular strikes us as being of a very ingenuous nature, especially as it appears to quite ignore the actions which are now waiting in the list for trial immediately after the Long Vacation on behalf of a large number of original shareholders, who claim to have their money returned, alleging all sorts of misleading statements in the prospectus. Amongst these litigants are some well-known public men, &c., and we fail to see any *bonâ fide* object in a new combination being started until a legal decision has been obtained in regard to the pending actions. The shareholders should bear in mind that in regard to these actions each and every director of the Company is a defendant, and in the event of judgment being in favour of the plaintiffs, every member of the Board might be held personally liable for the money originally subscribed. We can only assume that those shareholders from whom this latest circular purposes to emanate are unaware of what is going forward, as in the present state of affairs the benefit to be obtained for the shareholders by divided action is not apparent, although we fully appreciate that should the suggestion set forth in the document be arranged, then by whitewashing everybody concerned up to the present time, the relief to the defendants in the actions pending should be very great. We cannot credit that the shareholders upon whose behalf the actions are being brought will be parties to any scheme that would in any way prejudice their rights to recover monies subscribed, and until the Courts have decided the legal question of the liability of the directors, in our opinion the shareholders would be best advised not to consent to any alteration in the present position of the Company.

THE NEW FRENCH REGULATIONS FOR MOTOR-CARRIAGES.

We publish a translation of these elsewhere in our present issue. A glance at them will, we think, satisfy the most ardent advocate for official forms. The French have a love for minute regulations and bureaucratic methods generally, and they have certainly gratified this weakness in framing their regulations for automotive carriages. To say that these regulations are needlessly minute, vexatious, and wholly unnecessary, is no doubt calculated to shock the feelings of those who believe that the State should regulate all things, from the character of the music-hall variety show to the design of motor-carriages. We, however, think that the less the State or local authority interferes in these matters the better. Both in Great Britain and on the Continent the people simply groan under the load of law that we suffer to be imposed upon us, and, so far from deriving any benefit from these multitudinous regulations, it is doubtful whether any good purpose results from them. A few years ago we nearly stifled the electrical industry in this country by enwrapping it in many folds of law paper, but the industry had freer expansion in the United States, with the result that we now obtain much of our plant from that country. The French have so far led in automobile matters, but it looks as though they now wish to check their own progress by these absurd regulations. It is one of the most curious signs of the times, the regulation of all and every industry by the State. It is only right that admittedly dangerous industries should be under State regulation, but to subject a harmless and useful industry to an amount of official inquisition such as is indicated appears to us to be not only an arbitrary and uncalled for interference with individual rights but an absurd and impolitic proceeding altogether. The promulgation of such a mass of regulations has two effects—it checks the development of the industry and increases the already inordinately large army of public officials. We sincerely trust that such regulations as those we refer to will never be adopted in England. Our own view is that the common law is sufficient for nearly all purposes of life not excluding automobile traffic.

ON A COEFFICIENT OF MERIT OF PERFORMANCE FOR AUTOMOTOR-CARRIAGES PROPELLED BY OIL OR STEAM.

There is a great need of some simple formula which will express the relative merits of automotors. Speed is not the only thing that is wanted in a vehicle of this description, but economy in fuel and water consumption, which, of course, measures the cost of propulsion. For want of a better, we submit the following formula to our readers, and invite their opinions thereon :—

Let Ω be the mean speed over any given distance in miles per hour ;
ω the weight (tare) of the vehicle in lbs. ;
W the total weight of the vehicle loaded in lbs., with all stores, passengers, fuel, water, &c. ;
K the consumpt of fuel in lbs. while traversing this distance ;
C the coefficient of performance.

Then—

$$C = \frac{\Omega \omega}{K.\,W.}$$

We should say that this formula is a variation of one proposed by M. E. Hospitallier in *La Locomotion Automobile.* It is also applicable to cycles and ordinary vehicles ; only in their cases (K) would be omitted from the denominator.

TRACTION ON HIGHWAYS.

By Sir David Salomons, Bart.

Many tables giving the power required to draw given loads on roads with various surface conditions have been made by eminent engineers. Such tables are unsatisfactory, for the simple reason that no standards of road-surface exist, and to create them is not a simple matter. With traction upon rails the matter is otherwise--theory, with allowances, applies.

To place the subject before the reader in a manner easy to follow, let us consider a fly-wheel turning upon an arbor without friction. In this case the motion imparted to the wheel will urge it on at some given speed, never to stop. Friction alone will bring it to rest, and we have supposed this to be absent. If such fly-wheel is made to spin at double the first speed, the stored energy will be fourfold ; if at three times the first speed, nine times the energy will be stored. In other words, the energy stored will be proportional to the square of the speed, and such energy must clearly have been put in the fly-wheel at the start. Now advance a step further, and suppose the fly-wheel to run along a rail without friction, instead of spinning about an arbor. Then we have the simplest and ideal form of a railway train. The same law mentioned applies in this case, and may be expressed thus : the energy stored in the ideal train will be as the square of its speed.

A railway train in motion without friction is impossible ; hence energy has to be given to start it, and constantly supplied to make up the losses due to friction in order to maintain the speed. In the case of a railway the conditions are practically constant. It is otherwise with the high-roads. These may be as good as a railway in the case of newly-laid asphalte, and not much worse with new wood pavement ; but there are gravel, sand, macadam, rough, smooth, and dozens of other surfaces to be found, some in good and others in bad condition.

A motor-driven vehicle on a rough road meets with tremendous resistance, so much so that all the energy given to the carriage might at once be destroyed in overcoming friction. In such case the power continually supplied will be in proportion to the square of the speed. Fortunately, such bad roads are not the usual state of things, and experiments lead to show that the *average* power required on fair roads, such as a smooth macadam, is about four times that required upon rails. This figure 4 may be called the road-factor. Although the law of squares must exist for vehicles upon the highway, special conditions exist, due to the nature of the road and the small limits between the lowest and highest speeds usually employed —say, 5 to 12 miles per hour, which makes the power and speed vary in direct proportion for the rates mentioned upon the country roads of England.

To keep up a speed of 12 miles per hour upon all roadways usually met with, such rate not to be exceeded at any time, experiment shows that 10 H.P. per ton is about the power required. Consequently, if half this speed is demanded, 5 H.P. will suffice.

The brief manner in which this subject has been treated covers the ground, and shows the difficulties to be met with when attempting to tabulate the power necessary for traction on roads in a mathematical form. To sum up the foregoing :—

1. The power required upon average roads, compared with traction upon rails, is *four times.*
2. In practice, for speeds up to 12 miles an hour upon fair roads the speed varies with the power supplied.
3. To travel at 12 miles an hour on good and moderate roads, up and down hill and on the level, requires about 10 H.P. per ton.

Trial of a Stirling Motor-Carriage.—Messrs. Stirling, of Hamilton, furnish particulars of a trial of one of their carriages which took place recently on the Glasgow to Carlisle Road. The distance covered was 100 miles. The car left the works at 10.15, and travelled without stop to Abington (26 miles distance), where the cooling water tank was replenished. After about 15 minutes' delay the car proceeded to a point beyond Moffat, which was exactly 50 miles from home. The car then returned to Moffat, where a stay of an hour was made for luncheon. Moffat was left at 3.15, and the run of 21 miles back to Abington was made without stop. Here the cooling tank was again refilled. The remaining 26 miles was again accomplished without stop. A careful note was made of the amount of fuel consumed on the journey, and it was found to be exactly five gallons, which, at the retail price of 11*d.* per gallon, makes the cost of the 100 miles 4*s.* 7*d.* The carriage was of the wagonette type, and carried three gentlemen and about 100 lbs. of baggage. On the road traversed there were several long hills encountered, and on the return journey a stiff head wind was met. The entire journey was accomplished under nine hours, including the stoppages above referred to. The points of special importance which this trial has brought to light are, first, the distance which can be travelled without renewing cooling water, and the economy with which the car can be worked. Adding the cost of lubricant used, the total cost would work out at under 1*s.* 8*d.* per passenger. Messrs. Stirling add that the motor is built on the Daimler system, using light oil. They have built and sold over a dozen motor-carriages during the past few months, and these are now in regular use and giving every satisfaction.

REVIEWS OF BOOKS.

"Annuaire Général de la Vélocipède de l'Automobile, &c., 1897." F. Thévin et Ch. Houry. (Paris.)

This is an international cycle directory, which apparently contains the addresses of everyone engaged in the cycle industry in Europe. It is a well got up volume, and great pains have evidently been taken in its compilation. Although almost wholly dealing with cycles it also has an automobile directory, which, however, strikes us as rather incomplete, and much useful information is given relating to dues, tariffs, railways, &c. Cycle manufacturers will, we think, find this a decided acquisition to their office library.

"A Practical Treatise on Modern Gas and Oil Engines." By F. Grover, A.M.I.C.E. (The Technical Publishing Company (Limited); Manchester: John Heywood, 1897.) Price 4*s*. 6*d*.

We have been not a little indebted to our esteemed contemporary, the *Practical Engineer*, at various times for much useful information, and we have read with interest and appreciation the series of very excellent articles on gas and oil engines that have appeared in the pages of our contemporary and which are now most usefully republished in permanent book form. The author, Mr. Grover, is on the lecturing staff of the Yorkshire College, Leeds, which is tantamount to saying that he is an expert of no mean order. Very excellent work is turned out of Yorkshire College or originates from thence; and we rather envy those students who have had the advantage of the instruction of Mr. Grover on gas and oil motors, because, not only for the reason stated but as all old students know, no instruction is so permanent as that obtained through the medium of lectures which are followed by discussion between the students and the lecturer and between the students themselves, especially if in the latter case, as Professor Perry says in his "Calculus," it "leads to wrangling." Gas and oil motors are tantalising things—they are the media by which the heat energy contained in gas or oil is directly converted into work. Yet for regular performance of this duty they are not nearly so good as the worst steam-engine. Could we but do with gas and oil vapour what we do with steam (that is, in a mechanical sense), what an industrial revolution there would be. It is, no doubt, the great possibilities in gas or oil, or, perhaps, the fascination that surrounds the problem of the direct conversion of latent energy into exterior work that has caused many of our brightest and cleverest engineers to devote so much attention to gas and oil motors, but it is indicative of the difficulties of the problem that the Beau de Rochas cycle is still followed in the best designs. What should we think of a gun that required to be cleaned out every time it was fired; yet this is the characteristic of the earliest and latest types of gas and oil engines, although, as Mr. Grover shows, an impulse at every outstroke is obtained in some motors. Commencing with a slight historical sketch, we learn how, in 1862, the theory of the gas-engine was enumerated by Beau de Rochas, who, by the way, like most original inventors and thinkers, died recently in poverty, while many of those who manufacture engines on the cycle determined by him have made fortunes. This, of course, is quite in keeping with the eternal fitness of things. This Beau de Rochas cycle is now generally known as the Otto cycle, and Mr. Grover tells us in Chapter III "that since the Otto patent expired, the commercial value of other engines has much depreciated, and in many cases makers have abandoned their own patents in favour of the Otto principle." We think it would be as well, as a matter of abstract justice, if the name of Otto in this connection was dropped and the name of the acknowledged inventor substituted. Readers of the Automotor are, we think, aware that, as a rule, we refer to the Otto cycle under its more correct designation. The description of the various types of gas-motors occupies several pages, and each type is exhaustively analysed and illustrated. The directions for testing and indicating are unusually clear and practical, and many useful hints are given. The same remark applies to the analyses of coal-gas. The chapter on gas-engine designs is good, but might be more amplified. For instance, is cast-iron the most suitable material for oil-motors? Cylinders for vehicles and information regarding the limiting value of radiators would also be useful. Part II is a well-written but somewhat meagre account of petroleum oil-engines. All the leading makes are described and their various points discussed. No mention is made, however, of the De Dion, or Phœnix, light oil-motor, while the reference to the Daimler is very brief. We find, ourselves, considerable difficulty in obtaining reliable information of trials of these Continental motors, and perhaps Mr. Grover has experienced a similar difficulty. In conclusion, we must congratulate that gentleman on producing a well-written, technical work, eminently practical and containing no more science than is necessary. It is eminently a work for draughtsmen, foremen and others in charge of gas or oil-motor plant. We can also strongly recommend it to automobilists. The book itself is well printed and got up. It would make an excellent prize to students.

CATALOGUES.

Messrs. W. S. Sargeant and Co., of Chiswick, make a speciality of electric and steam launches for river and sea cruising, and send us a copy of their catalogue, which contains numerous illustrations of their various types of nautical automotors.

From the International Electric Company, of Redcross Street, London, we have received their latest catalogue and price list of electric fittings. We observe that there has been a considerable reduction in the prices of many descriptions of fittings, and also that this firm makes a speciality of apparatus for producing Rontgen rays.

Messrs. J. and C. Stirling, of Hamilton, N.B., have so well established themselves as manufacturers of motor-cars that they find it necessary to issue a catalogue describing the various types of these. There are no less than 14, ranging from the Stanhope car to the furniture van. We notice that, as befits a firm of such experience in carriage-building, the various vehicles are exceedingly well designed for their respective uses. The motors employed are Daimlers, which were fully described in our last issue.

The Mannesmann tube is largely used in motor-carriage construction as in many other branches of applied mechanics, and the high quality of the steel used enables a great saving in weight to be effected. The Company send us their catalogue, from which we learn that they have gone in largely for the manufacture of cycle and motor parts and accessories. There is an interesting record of tests to which their tubes have been subjected, and the results given are ample testimony of their great strength. The steel used has an average breaking strain of 35 tons per square inch.

We have received from Messrs. R S. Newall and Son (Limited), of Washington, Durham, the well-known pioneers of the wire rope industry, their catalogue of wire ropes. In this will be found some very useful tables applicable to every purpose for which wire rope is employed. Messrs. Newall and Son manufacture wire rope for aerial ropeways, suspension bridges, tramways, mines, &c. This firm were not only the first to rig a sailing ship with wire rope but they also supplied the wire rigging to the largest sailing ship in the world, the "France." Of these two vessels, separated in point of time by half a century, two very good photographs are given. This firm also manufactured the first cables used in tramcar propulsion. The catalogue is copious and interesting.

Those interested in electric tramways, railroads, &c., should obtain a copy of the voluminous and well illustrated catalogue issued by the Union Elektricilitats Gesellschaft of Berlin. This catalogue describes the various plants it has installed and gives a mass of interesting and accurate information. It is one of the best got up catalogues we have seen.

The International Motor-Car Company, of London, have issued a neat and well got up little catalogue of their various descriptions of motor carriages, ranging from the phaetonette to the cab and the van. The prices range from £140 for a phaetonette to £420 for a landau. We understand that over 800 motor-cars of this Company's type are in use on the Continent and in this country.

Messrs. Geo. Richard and Co. (Limited), of Broadheath, Manchester, have sent us a catalogue and price list of their specialities, including lathes, slotting and drilling machines, milling cutters, gauges, &c. We notice several new designs and inventions in the direction of accuracy of work and labour saving. This catalogue is well illustrated and described, and those thinking of putting down new plant would do well to peruse it. The prices seem to us remarkably moderate for such high class machines.

The Newton Machine Tool Works, of Philadelphia, send us a well printed, well illustrated, and neatly got up handbook of 180 pages, descriptive of their various machine tools. American machine tools are, we regret to say, occupying a favourite place with many firms, and it must be conceded that marvellous ingenuity is displayed in designing and making labour-saving devices. We notice that the Newton Company have greatly improved the milling cutters, and they can now run these at much higher speed than is usually the case.

Messrs. Davey, Paxman, and Co., the well-known engineers of Colchester, send us their catalogue of the numerous types of engines and boilers they manufacture. Probably no other firm in the world enjoys such a deservedly high reputation as this. Their semi-portable locomotives have been familiar sights in the London exhibitions of the last 30 years. Their position has been gained by supplying absolutely the best class of machinery. In the catalogue will be found full particulars of engines and boilers suitable for every purpose, together with a mass of technical information relating to steam, &c.

PRESENT STATE OF THE HORSELESS CARRIAGE INDUSTRY.

In the current issue of the *Engineering Magazine*, Mr. Worby Beaumont, M.I.C.E., &c., contributes a highly instructive article on this subject. He discusses the various trials that have taken place on the Continent, including the recent Paris-Dieppe Competition. As to the results, he says :—"From all this it will be seen that the victory has been almost entirely, year after year, with the carriages propelled by mineral spirit motors. It must, however, be noted that most of the prizes have been offered for, and have gone to, carriages carrying from two to four people. When larger numbers have had to be carried, steam has done good work, but only a few of the steam carriages have been small and light enough to run under the conditions which the oil motor vehicle is competent to meet. M. Serpollet made a number of excellent victorias, but their weight, although less than that of other steam-carriages, was more than that of the oil motor-carriages. This alone, although the variable power of the steam, and especially in the Serpollet, is a most valuable qualification for good and bad road travelling and hill climbing, has given the light oil motor-carriages every advantage. Every adverse condition of running at high speeds on common roads increases enormously with increase in weight. As soon as the weight is above that at which rubber tyres can be used, speed must suffer a reduction of 30 to 50 per cent. ; else wear, tear, breakage, and loss of power will result, with attendant discomfort for riders. The lighter Serpollet victorias of the type most recently made are light enough to be fitted with rubber tyres. They weigh only about 1,500 lbs., and, as they offer the many advantages of steam, they will probably remove many of the objections raised against the oil motor-driven vehicle.

"The experience in England with the lighter types of vehicles propelled by mineral spirit or oil is limited in comparison with that of the French—not perhaps one-fifth. So far as it has yet gone, it has only confirmed the facts proved in France—that the carriage driven by the mineral spirit motor is a very excellent makeshift, and, as now made by Panhard and Levassor, Peugeot Frères, Roger, and Delahaye, very difficult to improve or to describe as open to obvious improvement. They may be open to obvious objections, including vibration when the carriage is standing, and occasional smell of incompletely-burned oil when frequent stoppings and startings are imposed by street-traffic conditions ; but both these are objections which are lessening with almost every carriage that is built, although the means of their complete removal cannot be specified off-hand. In the early days of locomotives, coke ovens had to be put up as part of every great railway establishment, because for years they could not burn coal. The way to get over this difficulty could not be discovered in the hurry of a few months, but, after some years of every-day use of locomotives, the difficulty was removed in the simplest manner, the locomotive being used all the time, but denounced by every critic, whose useless and obstructive part is followed by similar critics of to-day concerning motor-carriages."

The First Death by a Motor-Carriage.—Last month we chronicled the name of the gentleman who will go down to posterity as being the first Jehu to be convicted of being drunk on a motor-cab. We now have to record the first death through a motor-cab. Juvenile exuberance is strongly manifested by the average London boy, who is *not* taught at the Board Schools how to behave, either at home or in the street. Indeed, the appearance of any novelty in the streets is as eagerly welcomed by the ordinary boy as "some new thing" was by the Athenians of old. Hence it is not surprising to read in the daily papers that as an electric cab was passing down Stockmar Road, it excited the interest of a large number of children who had just left morning school. One of the occupants of the cab cautioned the children to keep away from the vehicle, and naturally they did not, and equally naturally when about 200 yards away from the spot where the caution had been given a groan was heard, and the occupants of the carriage felt a sudden jerk. The driver at once looked at the wheels and saw that a child had somehow or other got entangled with the driving chain of the motor. The occupants alighted and doctors were at once sent for. Considerable difficulty was experienced in getting the child out, and it was not until one of the back wheels had been taken off that he was extricated, and by this time the poor boy had expired. It is thought that he got on the box at the back of the cab, and through his clothing catching in the cog he was drawn under the chain.

We are Glad to Hear It.—According to the *Pall Mall Gazette* the movement towards an introduction of automobile cabs—and omnibuses!—has reached Berlin. Some of the leading men of the electric establishments, among others Mr. Rathenau, the director of the Berlin Electric Works ; Mr. Borsig, the head of the largest locomotive-building establishments ; and Colonel Budde, the chief of the railway department in the "Generalstal" of the Prussian army, have founded a company for motor-cabs and omnibuses in the great towns of Germany, and they will begin their action at once in Berlin if the President of Police does not put a veto in their way. The Berlin pavement, mostly macadam in the principal thoroughfares, is exceedingly fit for motor-cabs, and there is every hope of success for such a company.

SELF-PROPELLED TRAFFIC ASSOCIATION.

LIVERPOOL AND DISTRICT CENTRE.

WITH reference to the proposed trials of the Self-Propelled Traffic Association (Liverpool Centre) which are to be held next year, the members of the sub-committee are now engaged in formulating the rules, conditions, &c., and will meet on the 15th instant, when it is hoped a draft will be decided upon for submission to the entire body of the Council. We hope the London Council of the Self-Propelled Traffic Association will also see their way to join in promoting these trials, so as to contribute to their success and make them as representative as possible.

WE regret to announce that the paper which Mr. Dugald Clerk had arranged to read before the Self-Propelled Traffic Association (Liverpool) on "Oil Engines for Motor-Vehicles," and which was postponed from March 2nd last, is now again indefinitely postponed, mainly in consequence of Mr. Dugald Clerk taking the view that the advance in this class of motor has not been sufficiently great during the past year to warrant him in dealing with the subject in detail this session.

THE PRETOT SPEED GEAR.

THE question of variable speed gear for motor-carriage builders who use oil-motors is the great crux in design, and it is usually surmounted in anything but a mechanically satisfactory manner. One of the best designs we have seen has been brought out by M. Pretot, of 42, Avenue Phillippe Auguste, Paris—the well-known motor-car builder. This gear is shown in section in Fig. 1. As will be seen it is of the epicyclic kind. For the following description we are indebted to *The Engineer*:—

A is a disc which can be either keyed directly to the motor or better driven by teeth in its rim from a pinion on the motor shaft. It carries four smaller wheels, *D*—*see* Fig. 2 also—by long spindles, *a*, *a*, to which are keyed four sets of stepped wheels, H^1, G^1, F^1, E^1, which gear with four central wheels, *H*, *G*, *F*, *E*. The latter wheels are quite independent of each other, and each one is provided with a separate wheel, *I*, controlled by a powerful brake. On the other side of the disc there is the double wheel, *B*, *C*, of which *B* is the chain wheel and *C* a toothed pinion gearing with the four wheels, *D*. Let us look now at the action of the mechanism. Suppose *A* is revolving at a constant speed, and the four wheels, *I*, are

FIG. 1.

allowed to turn freely, the brakes being loose, then *C* will not rotate, but *D* will revolve as it circles round *C*, and will impart motion to H^1, G^1, F^1, E^1, and they to *H*, *G*, *F*, *E*, in proportion to their relative sizes. Now, suppose the brake is applied firmly to *E*, then, as *A* revolves, E^1 rotates at a speed proportional to the difference in diameter between it and *E*, and imparts motion to *D*, which in turn passes it on to *C* and *B*, and so to the driving wheels, this representing the highest speed of the vehicle. The two other wheels,

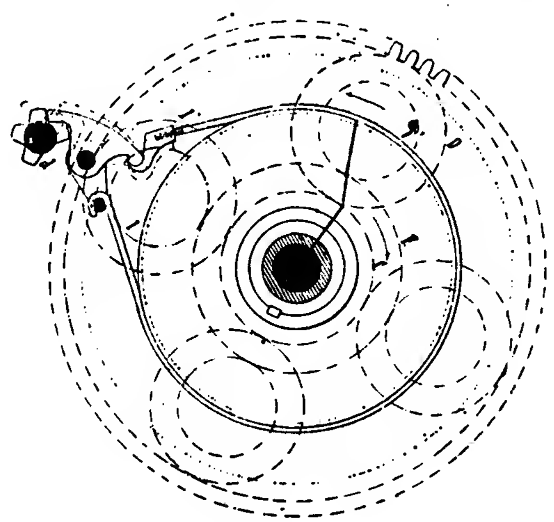

FIG. 2.

G, *F*, evidently give lower speeds, but when the pair, H^1, *H*, are put in action, the driving is reversed, and the carriage goes backwards. It is a little difficult to see at once why this should be. Two considerations will, however, we think, make it clear. In the first place, as we move from *E* to *G*, we get slower speeds until, if a wheel between G^1 and H^1, and of the same diameter as *D*, were used, no revolution of *C* would take place, because *C* and *H* would then be of the same diameter. We have, therefore, come from maximum to nothing, and any further step in the direction of increasing the cone wheel, as *H*, must represent a minus or reverse quantity. For a second consideration, suppose H^1 made so big, and H so small, that H^1 received no rotation at all from H—that is to say, suppose it was revolving round a single tooth in the centre of the shaft—then D would evidently be fixed, and its teeth would lock with C, which would then revolve in the same direction, and at the same rate as A. Now this is the reverse motion to that which all the other wheels impart, for they make C revolve, it will be seen, in the opposite direction to A. The speed which is imparted to B is easily found, and may be expressed by the formula—

$$\left(\frac{a}{A} \times x\right) - x,$$

where $\frac{a}{A}$ is the speed ratio between the stepped cones and x is the number of revolutions made by the disc. This is true only when D and C are of the same size, as in the case illustrated; if they are not of the same size the result found above has to be multiplied by their diameter ratio. The formula will be readily understood from the following considerations. Suppose all the brake wheels were loose and C fixed, and that A was caused to revolve. Then D and C being the same diameter, evidently in one revolution of A, D would make one revolution about its own axis. Now, this direction of revolution so produced is the same as that imparted by any one of the brake wheels. It is evident, however, that the only motion transmitted to C must be due to an excess of speed that D receives from the brake wheels over that which it would have by simply rolling round C, which means that the motion given to C equals the revolutions of C less the revolutions of A.

To Determine the Speed of Railway Trains.—Count the number of telegraph poles passed in a minute, double it, and the result is speed in miles per hour.

Fuel Cost Calculator.—We have received from Messrs. Meldrum Bros, of Manchester, one of their fuel cost calculators, and a most ingenious and useful little instrument it is. It is a double sliding rule made of stiff cardboard and about 6 inches by 2 inches, and can be conveniently carried in the pocket. By this automatic calculator the steam user can see at a glance what is the cost of the power he is employing, and also the weight of coal burned per I.H.P. per hour. It also enables him to see how the price of coal affects the cost of the production of power. To managers of mills and factories we can strongly recommend this miniature calculating machine. We would suggest to Messrs. Meldrum Bros. whether they could not bring out a similar one adapted for motor-cars showing the cost of running per hour and per week and per mile, for coal, electricity, and petroleum.

Magisterial Prejudice against Motor Vehicles.—We have often occasion to comment upon the discriminating harshness with which magistrates treat cyclists and drivers of automotors. From the provincial bumble, usually some petty horsey squire, we expect such things, but to find a London magistrate exhibiting such narrow-minded prejudice is simply deplorable. Yet more than one London magistrate shares the unenviable reputation for failing to do strict justice. At Marlborough Street Police Court recently the following parallel "judgments" (*sic*) were given :—

CABBY.—Leaving horse and cab absolutely unattended for thirty-five minutes, fined 1*s*.	MOTOR-CAR DRIVER. — Sitting in car outside owner's premises for fifteen minutes waiting orders—10*s*. and costs.

Comment is surely unnecessary—unless it be from the Lord Chancellor or Home Secretary.

LAW REPORTS.

MR. JUSTICE BYRNE, on September 15th, made an order for the appointment of a receiver and manager in the matter of the I.E.S. Accumulator Company (Limited), the action being brought by the sole debenture holder (Mr. Browning). Leave was given to act at once, and to borrow a sum not exceeding £1,000 for the carrying on of the business.

A PETITION was presented on September 7th to the High Court, by Messrs. J. K. and R. Lord, Barnbrook Boiler Works, Bury, Lancashire, for the winding up of New and Mayne (Limited). The solicitor for the petitioners is Mr. T. R. Birtwistle, Bury; the London agents, Messrs. Shaw, Tremellen and Kirkman, 14, Gray's Inn Square, W.C.

IN the Vacation Court, on September 15th, Mr. Justice Byrne, on the application of Mr. Rucker, a debenture holder, appointed a receiver and manager in the matter of New and Mayne (Limited), electrical engineers. No opposition to the order was offered. The receiver appointed was granted leave to act at once, and to borrow a sum not exceeding £1,500 for the purpose of the business.

UNDER the failure of Sidney J. Hersee, 14–15, Coleman Street, a meeting of the creditors was held on the 7th inst. at the London Bankruptcy Court. During the last two years he has been connected with the promotion of the Tavernier Motor Syndicate (Limited), Armstrong Dove Motor Syndicate (Limited), and other companies. The accounts filed under the proceedings show total liabilities £14,746, of which £4,492 are unsecured, and assets valued at sufficient to yield a surplus of £2,728 beyond the liabilities.

AT the London Bankruptcy Court, on September 23rd, the first meeting of creditors under the failure of Berkeley B. Bennett was held. The debtor about 18 months ago became a director of the British and Colonial Trading Corporation, and through it he became interested in certain company transactions. He has filed accounts showing a total indebtedness of £41,197, of which, however, only £2,135 is returned as expected to rank, and assets valued at £2,382. Amongst other things the debtor attributes his insolvency to a loss of £13,000 sustained by financing Mr. L. H. Goodman's undertakings, and to liabilities on unpaid calls, for shares underwritten, in the Leather Shod Wheel, £9,000, &c.

Daimler Company *v.* Bowen.

ON September 17th, before Mr. Justice Byrne, in the Vacation Court, on behalf of the Daimler Motor Company (Limited), counsel asked his lordship to restrain one, Bowen, from removing certain of the machinery and plant on premises and works on Eel Pie Island, purchased of the mortgagees by plaintiffs in May, 1896, the defendant's case being that the machinery in question was not included in the mortgage. The machinery having been actually moved and made ready for shipment, his lordship suggested an arrangement, as it was evident he could not order it to be replaced in working order pending the trial of the question raised in the case; but, difficulties being suggested by counsel who appeared for the respective parties concerned, the case was fought out at great length, and in the result it was agreed plaintiffs should take within a week.

Is a Motor-Van a Light Locomotive or a Legal "Carriage"? —A Point of Law.

AT Bow Street, London, on September 24th, F. Leaden, the driver of a motor-van, was summoned for allowing his van to stand in the roadway for 20 minutes without loading or unloading. The case was proved by P.C. 231 E who said he saw the van standing outside a shop in High Holborn from 12.30 to 12.50 on September 14th without loading or unloading. Mr. Houston contended at great length that this vehicle, being a motor-car, was to be considered, under the Light Locomotives Act, 1896, as a carriage, as was expressly laid down therein, and therefore it did not come within the Police Act, 2 and 3 Vic., under which this summons was taken out, but was subject only to the penalties provided by the former Act. He also called evidence to show that the van had only called for orders, and left immediately it was found that there were none. Mr. Lushington said that he could see no sort of reason why a motor-van should not be under the same regulations as any other vehicle for the conveyance of goods. The delay had been clearly proved, and he should impose a penalty of 10*s.* and 2*s.* costs. Mr. Houston said he should ask his worship in due course to state a case, and Mr. Lushington replied that he should have no objection to doing so if the application were made in the usual form.

More Furious Driving: Extraordinary Ignorance of Police and Court Officials.—Mr. Edmund Gibbs, of Lime Tree Terrace, New Southgate, was summoned at Marlborough Street, on the 8th inst., for riding a motor-tricycle to the common danger on the public highway. Constable Watts, C Division, stated that on September 23rd the prisoner, who was riding a motor-tricycle, went on the wrong side of the refuge at Oxford Circus. A number of persons were crossing the road at the time. He took the name and address of the defendant. Mr. Hannay: How did you catch the defendant? The Constable: I ran after him and hung on to his coat-tails. (Laughter.) Mr. Lyell (the Chief Clerk): What is a motor-tricycle? The Constable: It is a new invention. There is an electric battery to propel it, but one can work it with the feet without the aid of the motor. In defence, Mr. Gibbs said that the motor-power of his machine was petroleum, and not electricity. At the time in question he was only going two miles an hour, and was propelling the machine entirely by the aid of his feet. He could not move it at a more rapid pace when he only used his feet. Mr. Lyell: What about going on the wrong side of the refuge? The Defendant: I admit going on the wrong side of it. Mr. Hannay: That is in itself an offence. You must pay a fine of 5*s.* and 2*s.* costs.

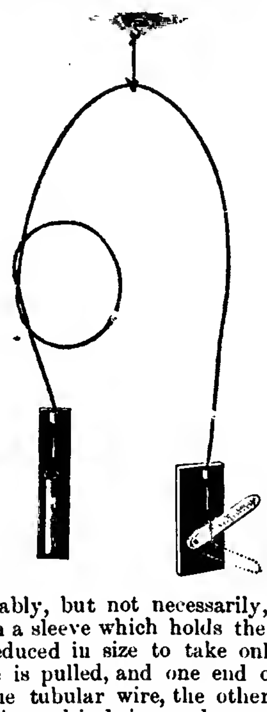
Furious Driving.—At the Gloucester Police Court on the 1st inst. John Taylor was summoned for furiously driving a motor-car on Sunday, September 19th. P.C. Millen said he was on duty in Northgate Street about a quarter to 8 o'clock on the evening of September 16th, when he saw a motor-car being driven at a speed of from 14 to 16 miles an hour. Witness called to the defendant, but he did not think he heard witness, as he was blowing the hooter. Two other young men were with defendant the whole time. Defendant said he had the car under perfect control, although he was going at about 14 miles an hour, and he could pull up within four yards. The Mayor pointed out the danger of such a practice, but as this was the first case that had come before the Bench they let defendant off on payment of the costs.

A Sensible Magistrate.—In a case heard recently in the Aberdeen Sheriff Court in which four cyclists were charged with racing on a section of the Newmachar Road, Sheriff Brown found the case not proven. He understood the prosecutor's contention to be that a bicyclist riding at racing speed, *per se*, committed a criminal offence, without reference to whether, as a matter of fact, danger was created to the public by the act. The prosecutor had not fully explained what the ratio of this view was, but his Lordship took it to be that from the conditions of the pastime in which he was at the time occupied, a racer, whether on a horse or a bicycle, was bound to shut his eyes to danger, and that the safety of the public was never in his mind at all. The presumption must be raised against him that cycle racing was of itself a danger to the public. The Sheriff had no doubt that many people had long ago reached the conclusion that even in their ordinary use such vehicles had added a new terror to life—(laughter)—but if they had to put up with them at racing speed, even on public thoroughfares, it was doubtless held that the Legislature must intervene to protect the public. He should not be at all surprised if legislation followed on the strength of the feeling in the public mind on this subject. But his Lordship was concerned at present only with the scope of the common law, and if a bicycle was a carriage, and so declared by statute, the prosecutor had never yet succeeded in obtaining a conviction against a driver of a carriage for furious driving, except on proof that in point of fact danger to the public had emerged. The evidence for the defence was strong enough to suggest that what was called racing speed in the present case was really of a somewhat harmless kind. (Laughter.) The decision of his Lordship was received with applause in Court.

A MECHANICAL TRANSMISSION SYSTEM.

Mr. Ernest M. Bowden, 9, Fopstone Road, Earl's Court, London, S.W., has patented a simple mechanism by which a small mechanical effort is transmitted round corners, or between points which are not fixed, without the use of such complications as pulleys, levers, or ball joints. It consists of a flexible pipe

formed of coiled wire, in which is another running longitudinally. At each end the inside wire projects beyond the outside, and is passed through a hole which is not large enough for the outside, or tubular, wire to go through; this hole, how-



ever, being preferably, but not necessarily, large enough part of the way to form a sleeve which holds the end of the outside wire, and then reduced in size to take only the inside wire. If the inside wire is pulled, and one end of it is drawn, say, an inch out of the tubular wire, the other end will be drawn the same distance in, and in being so drawn in it performs the operation which has to be done, although the wire cord formed of the two wires may hang loosely about in any position. The accompanying illustrations show the method of use. The wire cord is the only connection between two independent plates. Each plate has a small projection on it, through which the outside wire cannot go; but the inside wire is passed through the projections, and attached at one end to a lever, and at the other to a spiral spring. Notwithstanding that the model is suspended in mid-air, and that the cord is tied in a knot, the action is perfect and positive. When the lever is moved to the position marked by the dotted line, the spring is extended, and when the lever is released, the spring draws it back. For many purposes this method of transmission may be usefully employed.

We, however, question whether there is any novelty in this "patent." The combination is exceedingly simple and obvious, and must have been used in many operations.

DOINGS OF PUBLIC COMPANIES.

New Beeston Cycles and Motors.—Reconstruction Scheme.

After the remarkable and sanguine prospectus of the New Beeston Cycle Company (Limited), issued only as late as June last year, the circular proposing reconstruction just issued by the directors is but sorry reading. Possibly the shareholders have but little option in the matter, but we think it should require a good deal of consideration on their part before consenting to "sink the past" and practically place the original promoters in possession of the whole of the property and assets of the proposed new Company, by handing over £60,000 of debentures in the reconstructed Companies in exchange for £360,000 of vendors' shares in the present Company. Beyond this the shareholders are asked to provide further working capital at the rate of 3*s.* per share, the vendors, as far as we can see, not being called upon for any cash. It appears to us that as the whole of the cash originally subscribed by the shareholders has been absorbed, the vendors, who not only received the £360,000 in shares (which it is now proposed to exchange for the £60,000 of debentures) but a considerable amount in cash, should at the very least contribute to the required working capital *pro rata* with the other shareholders, to the amount of their holding in the old Company. It is for the shareholders to see to this at the meeting.

The following is the circular referred to, issued "by order of the Board," and dated September 29th last, in which the directors state that with reference to the notice of meeting sent out, the scheme embodied in the resolutions to be submitted at the meeting is the outcome of negotiations between the Board and the vendors extending over several months, with the object of (1) reducing the capital, which now stands at £1,000,000 nominal, of which £574,090 has been issued, principally in respect of goodwill and licenses; (2) relieving the business of the onerous burden of vendors' shares, representing over £360,000; (3) separating the cycle from the motor business. The scheme which is explained below will, in the opinion of the directors, place the business upon a thoroughly sound and independent footing and upon a proper business-like basis for the payment of dividends, and greatly increase the value of the shares, which now stand at a considerable discount, caused, no doubt, to a great extent, by the over-capitalisation of the Company. During the past season the Company has erected new works, which, with those previously in existence, are amongst the finest premises in the cycle trade. New machinery of the best class has been laid down for conducting the various departments on an economical basis. During the year nearly £70,000 has been laid out in additional buildings, plant, stock, &c., thus greatly improving the Company's position. Owing to the inclement season last autumn, and to the great difficulty the contractors experienced during the winter in getting building materials fast enough and sufficient men to rapidly complete the new works, the Company did not enter into full possession till April of this year, and it was later still before the new machinery was completed, and in full working order. Thus, in the new buildings, the management has only been able to take advantage of the latter part of this season's trade, while the output of the Quinton Works was much impeded by the introduction of the motor department. In consequence of these unforeseen difficulties the Company was unable to execute a large portion of the orders which had been placed with them, the profit on which would have represented a substantial sum. With respect to the motor department, the Board found themselves embarked in an entirely new industry, necessitating an expenditure of a very considerable sum of money in experiments, while continued changes in the construction of the motor-cycle were necessary to render it suitable for the English market. The great amount of care and attention and the large outlay which has been bestowed on this branch has, however, the directors are pleased to say, resulted in the fact that motors are now produced far in advance of anything previously in existence, either in England or abroad, so far as neatness of appearance, speed, power, easiness of control and absence of noise and vibration are concerned. The result of this expenditure will, your directors anticipate, enable the Company in the future to make a considerable profit on the motor business instead of, as in the past season, an outlay which practically absorbed the profits made in the cycle business. As this expenditure, however, was absolutely necessary in the establishment and development of this new industry, it must not be regarded as a loss; it should in the future be productive of satisfactory results to the new Company. The capabilities and achievements of the Company's latest motors will be appreciated by a perusal of the slip enclosed with the circular. The cycle department is undoubtedly profitable, but the motor department has yet to be commercially developed. The scheme is, therefore, designed to separate the cycle from the motor department, so that immediate dividends can be paid upon the former, while the latter is arranged upon such a basis that as soon as the machines now being turned out are exhibited to the public, and a demand thereby created, it also will prove to be an earning power; indeed, it will probably be more profitable than the cycle department. Two things are imperative for the entire success of the undertaking:—(1) Reduction of capital to a reasonable amount; (2) a substantial working capital to enable the Company to fully utilise the large works at its disposal. With this object in view, the Board has made terms with the vendors which enables the Company to be consolidated by reducing the share capital from £574,000 to £210,000 without reducing the holdings of the general body of shareholders. This, with debentures as referred to below, represents, in the opinion of the directors, the fair value of the cycle and motor businesses, buildings, building land, plant, machinery, stock, and other assets. The main points of the scheme as arranged are as follows:—Two companies to be formed, one called the Beeston Cycle Company (Limited) and the other the Beeston Motor Company (Limited). The former to take over as from September 1st, 1897, the Northern Works, and all the machinery, plant, and stock of the cycle department, all book and other debts, cash, &c., and to discharge all the liabilities of the Company up to that date. The books of the Company are at present in the hands of the Company's accountants. Subject to their examination, the tangible assets to be taken over by the Cycle Company are as follows:—Buildings (Messrs. Whittindale and Watson's valuation), £33,529 5*s.* 11*d.*; machinery, plant, tools, &c. (Messrs. Whittindale and Watson's valuation), £16,596 16*s.* 11*d.*; stock of finished and partly-finished machines, materials, &c., taken at or under cost, £18,521 3*s.*; cash, bills receivable, book and other debts, less reserves for bad and doubtful debts, £18,484 4*s.* 9*d.*; together, £87,131 10*s.* 7*d.*; less current liabilities, £9,721 15*s.* 11*d.*; total, £77,409 14*s.* 3*d.* The Motor Company to take over as from the above date the Southern Works, with the motor plant, stock, &c., also the motor patents and licenses, the former of which, subject to audit, stand in the books as follows:—Buildings (Messrs. Whittindale and Watson's valuation), £9,992 9*s.* 6*d.*; machinery, plant, tools, &c. (Messrs. Whittindale and Watson's valuation), £8,075; stock of finished and partly-finished machines and materials, taken at or under cost, £3,766 8*s.* 2*d.*; total, £21,833 17*s.* 8*d.* In addition to the above-named tangible assets, the Motor Company will possess a valuable license, covering a wider range of patents than the one now possessed by the Company. By it they will be able to make motors upon a simpler method than heretofore, which will cheapen the machines, while at the same time making them more readily saleable. Further, the new license, instead of being for bicycles and tricycles only, will also enable an entirely new branch to be developed — namely, the supplying of light stationary motors suitable for a variety of businesses. This license, as before stated, was the principal asset of the old Company, and is doubtless of considerable value. The capital of the Cycle Company will be £100,000, in £1 shares, divided into 40,000 5 per cent. preference and 60,000 ordinary shares, of which only about £90,000 will require to be issued. The capital of the Motor Company, £110,000, divided into 44,000 5 per cent. preference and 66,000 ordinary shares. The scheme entitles the shareholders, for every £10 share now held by them, to ten £1 shares, divided into five £1 shares in each Company—two preference and three ordinary. Each £1 share thus created will be credited with 17*s.* paid up, it being understood that not more than 1*s.* of the remaining 3*s.* is to be called up within four months. This is necessary to provide adequate working capital. The shareholders are offered an alternative in lieu of accepting the shares as above, to have allotted to them fully paid-up debentures, equivalent to 20 per cent. of each shareholder's present holding—one-half in each new Company. Terms have been made with the holders of vendors' shares by which they accept £30,000 debentures in each Company for their present holding of £360,000, an arrangement which must be of immense benefit to the general body of shareholders. A further important part of the scheme is that the whole of the company promoting element on the Board will be got rid of. Mr. Rowland Hill, J.P., and Dr. C. W. Iliffe (Coroner for North Warwickshire), who were the directors of the successful Quinton Cycle Company (Limited), and Mr. Samuel Gorton (who was general manager), have consented to act as directors. The scheme now placed before the shareholders has not been arranged without long and difficult negotiations, and it at one time seemed quite hopeless of accomplishment. The above-named directors feel convinced that the new arrangement will benefit all concerned. It should immediately lead to an increase in the value of the shares, and the possibility of substantial dividends upon the smaller capital will, the directors trust, secure the support of every shareholder to their proposals.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

	Capital.
Cosmopolitan Cycle and Motor Works, Ld.	£2,000
Croll's Improved Brake-holder Co., Ld. (34–36, Gresham Street, E.C.)	10,000
Electrical Vehicle Syndicate, Ld.	25,000
Fleet Cycle Co., Ld.	2,000
London Electrical Carriage Co., Ld.	100
,, ,, Coupe Co., Ld.	100
,, ,, Van Co., Ld.	100
Scott's Engine Syndicate, Ld. (Norwich)	2,000
Tudor Accumulator Co., Ld. (5, Cross Street, Manchester)	50,000
W. T. Ellison & Co., Ld. (Chaney Street, Manchester)	12,000

THE registered and general offices of the Australian Cycle and Motor Company (Limited) have been removed to Broad Street House, Old Broad Street, E.C.

THE offices of the British Electric Traction Company (Limited) have been removed from Great Winchester Street to Donington House, Norfolk Street, Strand, London, W.C.

Tudor Accumulators.—The Tudor Accumulator Company has been registered, with a capital of £50,000, to take over as a going concern the business of an electrical engineer and manufacturer of accumulators, carried on by Mr. Antoine B. Pescatore at 5, Cross Street, Manchester, and at the Barn Meadow Works, Dukinfield, to acquire certain patents of Henry O. Tudor, and to carry on the business of electricians, &c.

Rossleigh Cycle Company.—At the first annual meeting of the Rossleigh Cycle Company held last month in Edinburgh, Mr. Marshall, the chairman, in moving the adoption of the report—which recommended a dividend of 5 per cent. on the preference shares and 10 per cent. on the ordinary shares, placing the sum of £1,500 to the reserve and carrying forward £924—congratulated the shareholders on the progress the business had made. On the year there was an increase of £24,000. Regarding the motor-car question, the directors were of opinion that the motor-car business could be worked alongside of their cycle business. The report was adopted.

Yorkshire Motor-Car Company (Limited).—The first general statutory meeting of the shareholders of this Company was held last month at the Company's rooms, Albert Buildings, Bradford. Mr. A. H. Hutton, Chairman of the Company, presided. There were present Mr. Mollett, Mr. McEwan, Mr. Conyers, Mr. Cashburn, Mr. Childe, Mr. Roume, Mr. Whitfield, and Mr. Tuke. The chairman reported that the great difficulty with which the Company had had to contend had been in getting hold of cars, especially large ones, for passengers, and wagons for heavy loads. The Company was negotiating for steam wagons which would carry loads of two tons and upwards. Mr. Tuke reported that, although a new undertaking and working under the drawbacks named by the chairman, a profit had been made on the first three months' working, after paying all expenses. Cars were being sent on loan to all parts of the country, to Brighton, Bristol, Norwich, Hanley, Doncaster, York, &c. A licence had been obtained from the Bradford City Council to run a motor bus for hire in the streets. A resolution was passed appointing Mr. Skelton, of Bingley and Bradford, as a director of the company.

The Irish Motor-Car and Cycle Company.—Following the resolution to wind up, no time has been lost in making a first distribution of the assets. On the 21st ultimo, Mr. Robert Gardner, the liquidator, issued the following notice:—"On and after Monday, September the 27th, I will be in a position (upon receiving from you, either by post or personally at this office, the allotment letter and the bankers' receipt for the moneys lodged by you) to refund you in exchange therefor all the money paid by you upon your preference shares without any deduction whatever; and also the entire money paid upon your ordinary shares, save the first 2*s.* 6*d.* paid on application. As soon as the liabilities and costs have been ascertained and discharged there will be a further and final distribution amongst the ordinary shareholders." This is fairly prompt work, and although a good many shareholders are dissatisfied at not getting the whole of their money back at once, we hardly think they have anything to complain of, especially in view of the statement made by the chairman of the Company at the confirmatory meeting, that it was intended to enforce the company's claim under Mr. Baines's guarantee.

The Tendency of Oils to "Gum."—A convenient method of ascertaining the tendency of oils to "gum," owing to the absorption of oxygen—a defect common in animal and vegetable oils—is to place equal quantities of the oils to be compared simultaneously on an inclined sheet of glass or similar surface. In this way it will soon be apparent that the oil which absorbs the greatest quantity of oxygen will become the most "gummy." Although efficient, this method has been found too slow for many purposes. In Bach's method the oxygen is caused to act on the oil under the dual influence of heat and pressure in sealed tubes, and the oxygen taken up may be directly measured. The results obtained in this way on a number of well-known lubricants are given in the following table, which is taken from a paper read some time ago by Mr. Alex. E. Tucker, F.I.C., of Birmingham:—

One grain.	Absorbed oxygen. C.C.
Valve oil	0·10
Valvoline	0·45
Russian mineral oil	0·74
Lubricating oil, S.G. 0·877	0·70
Lubricating oil, S.G. 0·865	4·80
Re-distilled resin oil, V.G. 0·963	76·30
Resin oil	181·00
Olive oil	144·00
Rape oil	166·00
Cottonseed oil	111·00

A NEW-FELT WANT.

(From the *Daily Mail.*)

Mr. Editor,—

I am at a Lost to know what kind of Blow to give with the wishel for the motor-cabs perhaps some of the readers of your valueable paper may kindly inform me one who as Been 14 years at a corner in the Fashionable West end of London will greatly oblidge yours truly C. E. C.

To the Editor of the *Daily Mail.*

In answer to "C. E. C.," the proper way to whisthel (not "wishel") for a motor-cab is to ring a bell. I am a cabdriver, so I ought to know. JOHN MULDOON.

CORRESPONDENCE.

. *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

. *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

SOME ESTIMATES OF THE HORSE.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I observe in one of your articles a reference to the difference of opinion in regard to the horse as between Mr. Preece and myself.

When I was at college one of the subjects for my degree consisted of comparative anatomy, the study of which I have never regretted, as it has rendered me good service on many occasions in designing apparatus.

It is quite clear that Mr. Preece has not had the good fortune to study anatomy, or he would have come across the celebrated book of the late Professor Huxley on the Vertebrata, in which he deals with the anatomy of the horse, and shows how exceeding perfect a machine it is.

The heavy body of the animal is suspended by the equivalent of Cee springs, far more perfect than those employed by carriage builders. In fact, with all the improvements which have been made in regard to machinery to this period, there is not a single invention which can approach in its perfection the principles which are found to exist in the animal kingdom, such, for instance, as complete elasticity of motion—any device equivalent to the muscle or material which can replace itself, after wear, throughout its mass, by a system of feeding. And, lastly, no machine has any property approaching to that possessed by the lowest of animals, generally called instinct.

My opinion is not in any way changed that the horse is a far more perfect motor than any which can be designed by man, although I am ready to admit that machines for many purposes have the advantage.

The horse will no more disappear by the development of motor traffic than has the prophecy come true that such a result would follow the introduction of railways. The number of horses in use at the present time is largely in excess of that existing when railways started, due, no doubt, to the increase of population combined with new demands, and these factors are not likely to be eliminated in the future.—Yours faithfully,

David Salomons.

[We have no comment to make on the above letter save that we agree in the main with our correspondent, and we note with satisfaction that he has been a disciple of that great man Huxley.—Ed.]

DESIGNING MOTOR-CARRIAGES.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—I find the Automotor a very useful and well edited journal, yet I think you might perhaps be able to give more particulars concerning the engines of steam carriages for turnpike roads.

What is wanted in the cases referred to is :—

Number of cylinders; diameter of cylinders; length of stroke; state how many are high pressure; revolutions of crank shaft to road wheels; diameter of same road wheels; amount of heating surface in boiler; steam pressure in boiler; weight of steam carriage.

The above information would enable an engineering man like myself to make calculations, and be a great help in designing a steam carriage.

I have studied the subject for 29 years, and have had some experience with traction engines. I have now designed a simple, compact, and neat steam carriage, with three-speed gearing. The driving and steering are done by one man, who sits at the back end of carriage. It will carry five people.

To construct a steam carriage to the best advantage I consider it necessary that it should have three-speed action gearing—one gear for level roads, another for moderate incline, and a third for very steep hills.

Apologising for troubling you.—I am, yours truly,

W. Stanley.

St. Mary's Gate, Chesterfield.

[The design of road locomotives is well thrashed out, and the information can be obtained from the price lists of Burrell, or Aveling and Porter. We appreciate our correspondent's good opinion.—Ed.]

THE DAIMLER FRICTION GEAR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I should esteem it a great favour if you would give me particulars of the friction gear used by the Daimler Company, and illustrated in your last issue, in their oil launch; whether they have the rights, the number of patent, &c.—Yours, &c., A. Dabson.

[We could not express any opinion as to any "rights" the Daimler Company may have in this or any patent. Your best course is to consult a patent agent and have a search made.—Ed.]

A HORSE AND VAN OR AN AUTOMOTOR VAN.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Owing to the extension of my business I find it necessary, in order to supply my customers at a distance, to have another horse and van. Having heard a good deal about motor-cars I take the liberty of asking you for a candid opinion and advice on the subject. Shall I be wise in placing an order for another horse and van, or shall I have an automotor one? I know the latter are very dear, but the advertisement would be worth something to me, as in this town there are no motor-vans used as yet. What kind do you recommend?—Yours faithfully,

A Belfast Grocer.

[We refer to this in an article entitled "Kelvin's Law of Economy."—Ed.]

THE UNIVERSAL MOTOR-CARRIAGE AND CYCLE COMPANY (LIMITED).

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Can you give any information as to the proceedings, &c., of this Company? What do they manufacture or sell, what dividend do they pay, and what is the present price of their stock?—Yours faithfully, Broker.

[We know nothing about the Company in question beyond that the original Company was registered under the title of British Motor-Carriage and Cycle Company.—Ed.]

FORE AND AFT STEERING.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—In connection with the vexed question of steering, it may not be out of place to remark that there is really no reason why steering wheels should not be placed at *both* ends of a vehicle. The driving wheels would be placed between them (there is not, I believe, any law against exceeding four wheels), and, if midway, this would mean the reduction of the steering length by one-half, with a correspondingly reduced play for the steering wheels. In practice, the driving wheels would probably be placed more forward, making a long composite six-wheeled vehicle, the fore part acting as a locomotive and the hinder part representing a car attached.—I am, &c., A. J. A.

October 2nd.

P.S.—Possibly, where *plateways* are used for heavy goods traffic, the front steerers might be disconnected and coupled to the drivers immediately behind them.

[We hope to discuss the principles of steering mechanism shortly.—ED.]

PROCEEDINGS OF TECHNICAL SOCIETIES.

Mechanical Propulsion on Canals.*

THE really complicated subject of traction on canals involves at the outset the determination of the resistance of a boat in a channel of restricted section. This resistance depends in some way upon the ratio $\frac{\Omega}{\omega}$ which the wetted cross section Ω of the canal bears to the immersed midship section ω of the boat. Although this ratio may remain the same, the resistance varies according as the channel becomes shallower and wider, or deeper and narrower; and in a less degree it also varies with the roughness of the channel bed. Again, the form of the boat, while its immersed midship section may remain unchanged, is an important factor in the determination of the resistance; although in a canal the actual form of a boat has not so much influence on the resistance as in open water.

De Mas.—The most exhaustive and important experiments that have yet been made upon the resistance to traction on canals were commenced in 1890 by M. de Mâs with the chief kinds of boats in general use upon the canals in the North of France; and his first experiments were made upon the River Seine, with a view to determining the resistance of the boats in an expanse of smooth water. The wetted section of the Seine above the weir of Port-à-l'Anglais, where the experiments were made, is at least 5,651 square feet, while the boats tried were about 16·4 feet wide and immersed 6·2 feet deep, that is, about 102 square feet of immersed section: so that the ratio n of the sections $= \frac{\Omega}{\omega} = \frac{5,651}{102} = 55{\cdot}4$; and therefore the results may be taken as if the boats had been tried in an unlimited expanse of water. The experiments showed that the ordinary formula $R = K \omega V^2$ does not hold; that the various elements on which resistance to traction depends are not connected with one another by this or any other proportion of similar form. This is clearly seen from the following deductions, firstly for boats in rivers, and secondly for boats on canals.

Boats in Rivers.—1. *For a boat worked at a given speed the resistance to traction is* not *proportional to its immersed midship section* ω. This fact is shown by the following Table 1, taken from the results of M. de Mas' experiments upon a boat tried at successive draughts of 3·28 and 4·27 and 5·25 feet; the figures are embodied in M. Derome's paper upon this subject, which was presented to the sixth International Congress on Inland Navigation in 1894, and to which the author is indebted for the following information. It will be seen that for one and the same speed the resistance to traction increases less quickly than the immersed section.

* Abstract of paper read by Mr. LESLIE ROBINSON at the Institution of Mechanical Engineers.

2. *For a boat of given draught the resistance is* not *proportional to the square of the speed.* Although this fact is evident from Table 1, it is more clearly demonstrated by the results of a series of experiments on the different kinds of boats of which the resistances are given in Table 3. The results for the "Toue" have been worked out in Table 2 at a draught of 3·28 feet and at speeds of from 1·64 to 8·20 feet per second, or 1·12 to 5·60 miles per hour; and also at a draught of 5·25 feet for the same speeds. In Plate 1 this Table

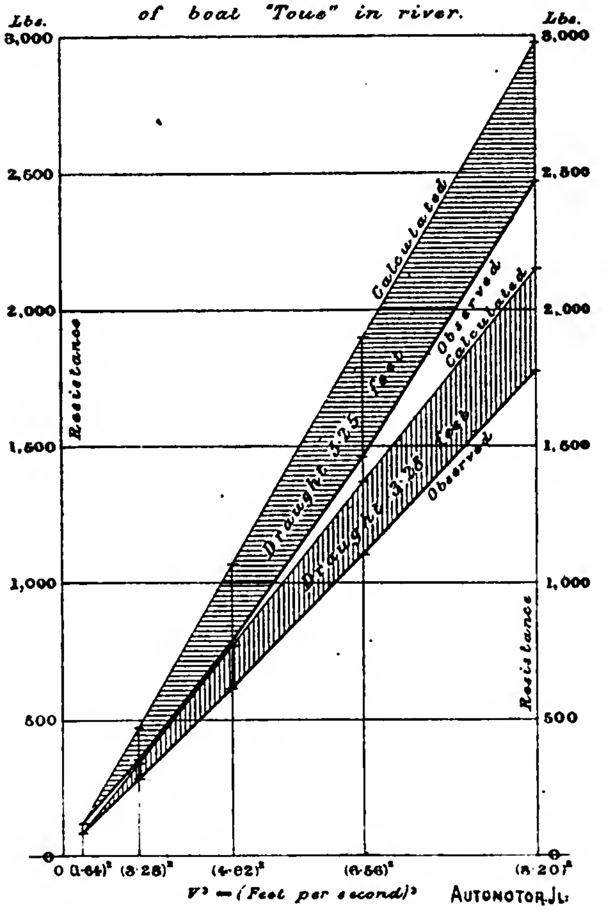
PLATE 1.

Observed and Calculated Resistance to traction of boat "Toue" in river.



has been plotted as a diagram, giving the resistances actually observed, and as calculated from the formula $R = KV^2$, where the value of K is 31·97 for 3·28 feet draught, and 44·25 for 5·25 feet draught. It would thus seem that the greater the draught of the boat the larger is the discrepancy between the observed and calculated resistances, especially at the higher speeds.

3. *For a given boat the coefficient of resistance to traction* $\frac{R}{\omega V^2}$ —being the ratio which the resistance R to traction bears to the immersed midship section ω and to the square of the speed V—*is not independent of the speed, as it is assumed to be in the ordinary formula* $R = K \omega V^2$. This ratio varies as shown in Table 4.

Table 4.—*Coefficient of Resistance to Traction in Rivers.*

8·20	67·24	—	0·4583	0·3547	0·2780

4. *For a given speed and draught the resistance to traction varies considerably, according as the wetted surface of the boat is more or less smooth.*

5. *For boats of the same form, and under otherwise similar conditions, and within the limits of the experiments, the resistance to traction is entirely independent of the length of the boat.* On this point M. de Mas experimented with three boats of the "Flûte" build, having the same breadth amidships, and fore and aft shapes as nearly identical as possible, and differing only in the length of hull below water, which with a draught of 5·25 feet was as follows:—"Alma" 124·64 feet; "René" 99·44 feet; "Adrien" 67·44 feet. As shown in Table 5, and plotted in Plate 3, the total resistances of these

Table 5.—*Resistance independent of Length of Boat. See Plate 3.*

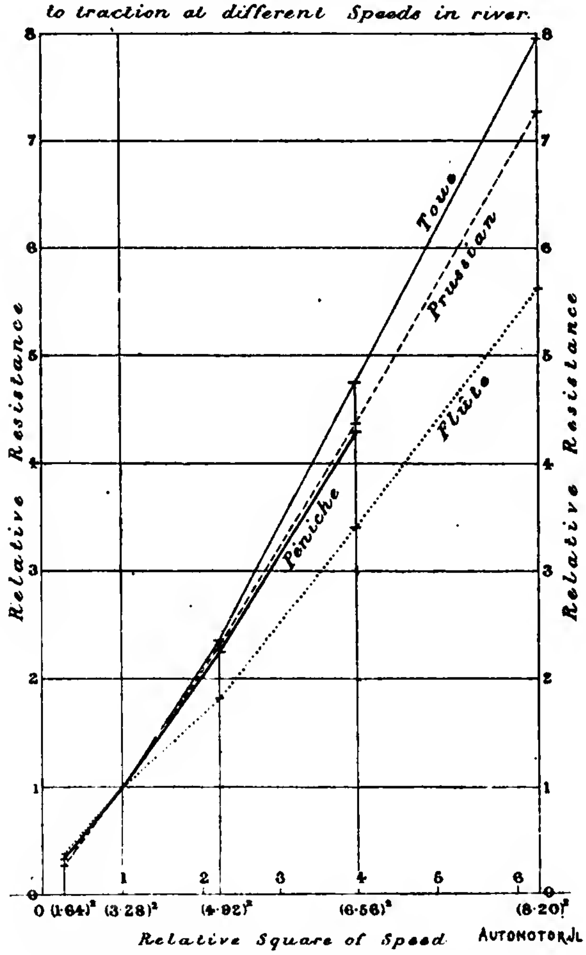
	feet	tons	lbs.	lbs.	lbs.	lbs.	lbs.
"Alma" ...	124·64	286	119·0	357	783	1464	2487
"René" ...	99·44	—	112·4	353	783	1466	2469
"Adrien"	87·44	148	112·4	353	783	1466	2469

three boats at the same speed were almost identical. The "Alma" and "René" were subsequently tried again at the same speeds as in Table 5, but with 1 foot less draught, namely 4·25 feet, when they gave resistances absolutely identical with each other. From these results it also follows that the resistance due to the build of the boat does not vary in the ratio $\frac{b}{L}$ which the breadth b amidships bears to the length L.

Boats on Canals.—The same boats that had been tried on the River Seine were subsequently tried on the Bourgogne Canal at speeds increasing from 0·56 mile per hour by increments of 0·56 up to 2·8 miles per hour; and it was again found that, other conditions remaining unchanged, and within the limits and under the conditions of the experiments, the resistance to traction is independent of the length of the boat. It was also found that there is a considerable increase in the resistance to traction on passing from the river into the canal. Table 6 is drawn up for different boats and different draughts, and for speeds of 1·64 and 3·28 feet per second, or 1·12 and 2·24 miles per hour, which appear to be the extreme limits of speed adopted and practicable on French canals; R represents the total resistance to traction in the canal, and r in the river; $\frac{R}{r}$ is the ratio of the two resistances.

Plate 2.

Relative Resistance of four Boats to traction at different Speeds in river.



One noticeable fact which appears from Table 6 and from the plotted diagram, Plate 4, is that, for the same value of the ratio $n = \frac{\Omega}{\omega}$, the less the resistance to traction of a boat in the river, the greater will be the relative increase in the resistance to traction when the boat is transferred from the river into a canal: or inversely, the larger the tractive force in the river, the smaller will be the relative increase on transference into a canal. Thus the "Toue," requiring 97·0 lbs. tractive force in the river, requires when transferred to the canal, 240·3 lbs., being an increase of 2·48 times; whereas the "Péniche," requiring 224·9 lbs. tractive force in the river, requires in the canal only 379·2 lbs., that is, an increase of only 1·69 times against 2·48 times for the "Toue." The build of the boat is less important in a canal than in a river; hence it will not exert so great an influence on the resistance to traction.

PLATE 3.

Resistance independent of length of boat.

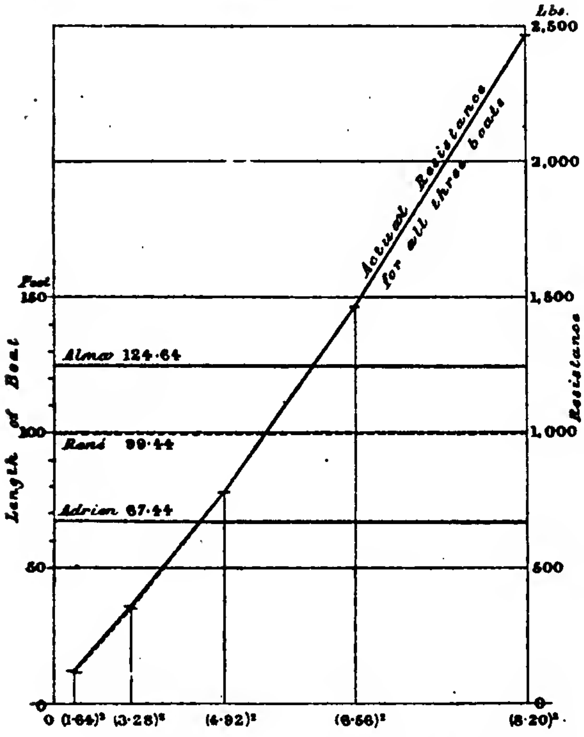


PLATE 4.

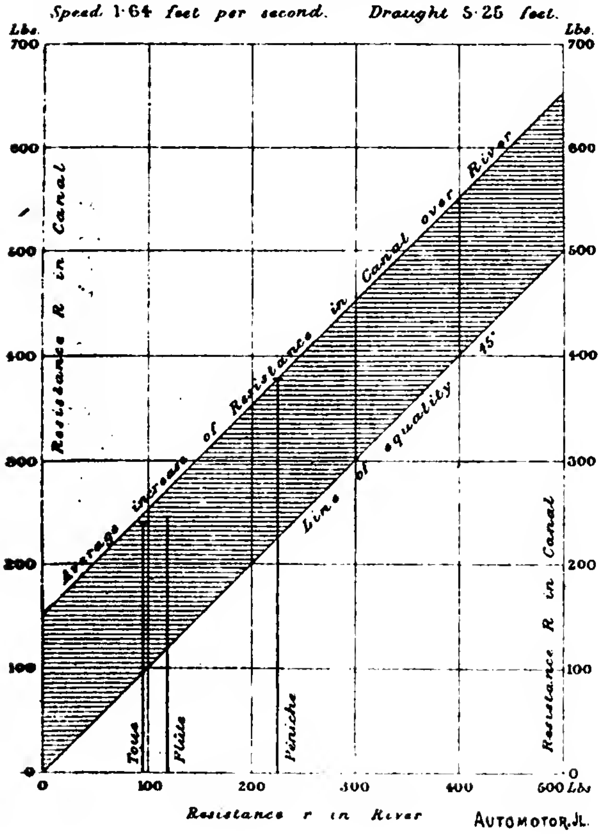
Resistance to traction in Canal and in River.

Speed 1·64 feet per second. Draught 5·25 feet.



Another notable fact observed from Table 6 is the rapidity with which the ratio $\frac{R}{r}$ of the resistances decreases when the ratio $\frac{\Omega}{\omega}$ of the sections increases.

(To be continued.)

Mechanical Traction.

AT the Camera Club, 28, Charing Cross Road, on October 7th, Mr. J. H. Knight delivered a lecture on two years' progress in mechanical traction.

Mr. KNIGHT commenced by stating that it was thought by many that no progress had been made during the past two years, that the public had expected that no sooner were mechanical vehicles permitted to run than the horse would disappear from our streets; but quiet progress had been made, and many more motor-cars were running than the general public were aware of. The lecture was illustrated by 75 lantern slides—the Benz, the Daimler, and other motor-cars being described, and photos and diagrams of same shown—among them Mr. Knight's motor-cycle, made in the summer of 1895, which was the cause of its maker being brought up before the Farnham magistrates and fined.

The Dion Bouton steam cars were shown on the screen, also a diagram showing the boiler of the same. Serpollet carriages were described at some length, and a diagram of the latest type with a petroleum fired boiler was shown; this, it is claimed, will carry two passengers 90 miles with 5¼ gallons of ordinary paraffin oil. Electric carriages were briefly touched upon. Mr. Knight complained that makers of these vehicles were very reluctant to give any information respecting them.

The lecture was followed by a discussion. Mr. H. A. O. Mackenzie spoke in favour of steam, he having constructed a steam brougham about 1872.

Mr. W. Worby Beaumont said thatuntil last November no road trial could be made in this country, and unless a vehicle were well tested on the road it would be useless to expect the public to purchase it, hence months must be spent in experiment. The French had had a great start of us, and had in many ways solved the problem. He alluded to several carriages he had seen in France during the summer, one having travelled from Moscow to Dieppe to take part in the run from Paris to that town in July last.

Mr. Knight, in replying to a question, said there was no difficulty in regulating the speed of a petroleum car if the governor were controlled by a spring that could be compressed by a lever at the will of the driver.

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "The Automotor and Horseless Vehicle Journal" by Herbert Haddan and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

*** *At the request of a number of subscribers we are pleased to announce that for the future we have arranged to more thoroughly cover the field of completed Patents referring to the Motor-Car Industry, by reproducing the latest Specifications and Diagrams.*

Specifications Published.

14,303. Horseless Carriages. James Garvie, Devanha House, New Southgate, Middlesex. June 27th, 1896.

Relates to horseless carriages, and consists chiefly in arranging the engines within or upon the axle of the road wheels, the said axle being made hollow or tubular to contain the engines.

The said axle may itself constitute the cylinder or cylinders of the engines and in this case the engines would be situated at right angles to the longitudinal axis of the vehicle and would be preferably placed opposite to each other with the crank shaft located between them and at right angles thereto. When the cylinders are arranged in this manner a third cylinder may be used in conjunction with the two others, this third cylinder being situated either vertically above or below the crank shaft or at any suitable inclination thereto. This third cylinder would act to carry the crank over dead points.

Any suitable means may be employed for communicating motion from the crank shaft to the road-wheels, appropriate devices being supplied for reversing the motion.

23,350. Apparatus for Forming and Regulating the Combination of Oil with Air for Oil Motors. Sir William Arrol, Dalmarnock Ironworks, 241, Baltic Street, Glasgow, and George Johnston, 94, Hope Street, Glasgow. October 21st, 1896.

In the improved apparatus constituting the invention a piece of woven or other suitable permeable material is arranged so that at one place it passes through and is saturated with the oil, whilst at another place the air, preferably heated, is made to pass through the oil-carrying permeable material, and thence through a passage leading to the motor, the air in its passage taking up some of the oil.

Fig. 1 is a vertical section of the apparatus, and Figs. 2 and 3 are, respectively, a side elevation and a transverse vertical section of a part of the apparatus.

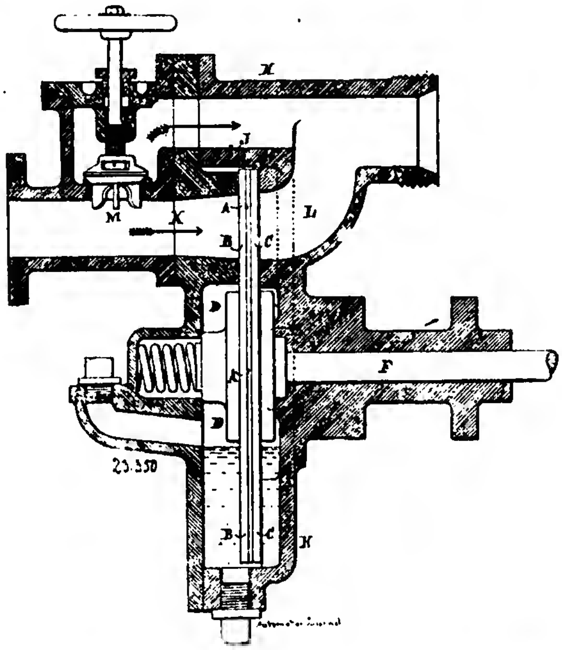

Fig. 1.

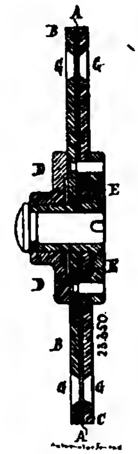

Fig. 2. Fig. 3.

The oil-carrying permeable material, A, is placed between two discs, B, C, held and pressed together by screwed bosses, D, E, on a spindle, F, which is made to rotate at a suitable speed by gearing such as a worm wheel and worm (not shown). Annular sets of holes, G, are formed in the two discs, B, C, to give the oil access to the permeable material, A, and to allow the air to pass through it. The discs, B, C, are enclosed in a casing, H, the lower part of which is supplied with the oil; and they are partly immersed in the oil. At the upper part of the casing, H, the discs, B, C, pass through a narrow space, J, and across openings or passages, K, L, on each side, the passage, K, on one side being the inlet for the air and the passage, L, on the other side communicating with the motor (not shown). The air is thus compelled in passing from the passage, K, to the passage, L, to go through the holes, G, and the oil-saturated permeable material, A, the holes, G, being brought round in succession by the rotation of the spindle, F, and the air in its passage thus taking up some of the oil. A by-pass passage with an adjustable regulating valve, M, is also provided to allow some air, if required, to mix with the oil-saturated air.

16,079. Motors and Transmission Gear. George Dominy, King Street, Weymouth, Dorset, and John James Henry Sturmey, 19, Hertford Street, Coventry, Warwick. July 21st, 1896.

From a steam generator a steam pipe is led into a suitable chest. The end of the pipe is preferably located in the lower part of the chest in a horizontal or other suitable position, and is directed towards the blades of a light vertical fan wheel adapted to rotate at a high speed in the said case. The lower part of the case is filled with water or other suitable liquid, which preferably does not reach up to the wheel, the level being prevented from rising by an overflow pipe hereinafter referred to. Around the end of the steam pipe we arrange a tapered or other suitable nozzle in such a manner that the water is able to enter the back and underside of the nozzle, and is carried therethrough by the action of the steam—on the principle of the well-known injector for supplying steam boilers with water. The nozzle may form a projection from the side of a vertical hollow cylinder or case fixed to the bottom of the chest or special frame in such a way that the water may freely enter the cylinder; the steam pipe may be led through the wall of the cylinder opposite to the nozzle. The lower part of the

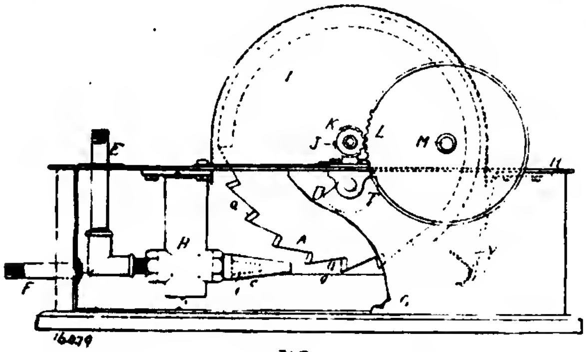

FIG 1

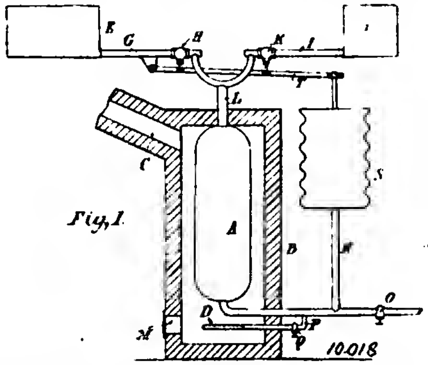
nozzle-cylinder may be provided with a strainer. The nozzle may be adjustable as to angle and to adapt it to the variable pressure of steam, quantity of water, temperature, and other varying circumstances in any suitable manner. The water on being forced from the nozzle impinges on the blades and rotates the wheel. Beyond the wheel a plate, with its upper part curved forward towards the nozzle, may be fitted to direct the disturbed water downwards or otherwise, and so back to the cylinder and nozzle. The spent water may drive an assistant wheel. A loosely fitting float or floats may be employed to help prevent the water splashing unduly. The fan is adapted to rotate at a high speed, though it is anticipated that a lower speed than is employed with steam turbines at present in use will be sufficient to produce the same amount of power. The water in the tank will soon become heated by the steam and cause the condensation to become less rapid. The overflow water rising from condensation may be returned along a tube having its exit end below the level of a small tank of water and thence into the boiler. The said tank (which may be arranged to operate as a cooler) and the chest before mentioned may be made steam tight or not, or up to a pressure regulated by a suitable valve or valves. The overflow or pressure from the chest is preferably made under water. The shaft carrying the fan is preferably geared to another shaft adapted by any suitable means to revolve at a much slower speed but with correspondingly increased power. The first or any shaft or a connection thereto may be made flexible so that its motion may be transmitted in an indirect line with an avoidance of complicated mechanism.

10,018. Motive Power Apparatus Consuming Liquid Fuel, such as Petroleum and Heavy Oils. Howard Lane, 184, Corporation Street, Birmingham. May 11th, 1896.

This invention consists in the construction of apparatus forming an adjunct or attachment to motors of the class described and whereby the nature of petroleum and the like is altered by decomposing it in a retort along with water or along with gas-engine exhaust products, viz., steam or aqueous vapour and carbonic acid.

A is a retort set in a brickwork chamber, B, lined with refractory material and containing at the lower part or furnace or heating apparatus of any suitable kind. The retort is by preference fitted with iron turnings or fragments to present a large surface. C is the flue passing off to the chimney. The heating apparatus is by preference a ring burner, D, for gas. E is an oil reservoir, and F a water reservoir. the pipe, G, from the oil reservoir, E, is provided with a valve, H, and the pipe, I, from the water reservoir, F, is provided with a valve, K. Both pipes are connected to the top of the retort, A, by the pipe, L. The burner, D, is lighted through a firing hole, M. From the bottom of the retort a pipe, N, leads off to the motor cylinder and is provided with a valve, O. The burner, D, is supplied with gas by a branch pipe, P, with a valve or cock, Q. Another branch pipe, R, leads to an expansible and collapsible weighted gas holder, S, which is connected by a lever, T, or other means to the valves, H and K. The petroleum and the water may, if desired, be supplied by pumps instead of by gravitation; and in that case I regulate the rate of pumping automatically by the rise and fall of the gas holder.

To operate the apparatus a little cotton waste is placed in the furnace and a little oil admitted from the reservoir, E, into the retort by the valve, H, or by a separate valve. This oil gravitates without being volatilised and drips upon the cotton waste in the furnace, which is then ignited and the retort gradually heated up. As soon as the retort is hot the water inlet valve, K, is also slightly opened. The petroleum and the water together are now in the retort transformed into carbonic oxide and hydrogen because the oxygen of the water combines with the carbon of the petroleum forming carbonic oxide, and the hydrogen both of the water and of the petroleum is liberated in a free state.

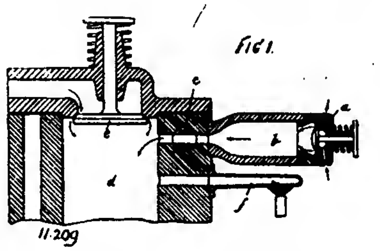


In case the pipe, I, is connected to the exhaust of the motor and the latter is started a mixture of carbonic acid gas, steam or aqueous vapour, and nitrogen finds its way from the exhaust through the valve, I, into the pipe, L, where it commingles with the petroleum admitted by the valve, H, and enters the retort, wherein the carbonic acid combines with the carbon of the petroleum forming carbonic oxide and the hydrogen of the oil is liberated. The nitrogen forms a neutral or diluting gas.

If the make of gas is in excess of the requirement of the motor, the gas holder, S, expands and closes the valves, K and H, partially or wholly. The supply of gas to the furnace is adjusted or regulated by the valve, Q, and is comparatively small in quantity.

11,209. Vaporisers for Petroleum-Engines. Osvald Bomborn, Querstrasse 4[II], Leipzig, Lindenau, Germany. May 22nd, 1896.

This invention relates to a vaporiser for petroleum-engines, its arrangement being such that the hot gases resulting from each explosion are utilised for heating the vaporiser, and this without there being any danger of the gases, or mixture of vapour and air, being ignited within the vaporiser. To effect this a valve opening communications between the vaporiser and the cylinder in which the explosions take place, is closed during the period of compression, *i.e.*, during the upward stroke of the piston, and opens again only during or after each charge is exploded, the resulting hot gases being thus admitted into the vaporiser.



The latter may be heated either by allowing such gases to pass directly into same, or indirectly, by admitting the gases into a chamber surrounding the vaporiser.

The quantity of petroleum necessary for forming the vapour enters the vaporising chamber through a spring-controlled valve at each period of suction. The hot walls of the chamber vaporise the petroleum, and these vapours then pass through the valve into the cylinder and thus mix with the air entering through the valve. On the return of the piston, therefore, such mixture of petroleum vapours and air is compressed, the valves being at the same time closed.

The compressed mixture is now ignited in any suitable manner, for instance, by means of an igniting tube, and the hot gases resulting therefrom pass during, or immediately after the ignition of the charge, from the cylinder through the now open valve into the vaporiser, and thus heat the latter, whereas a premature ignition of the charge by the hot walls of the vaporiser is prevented.

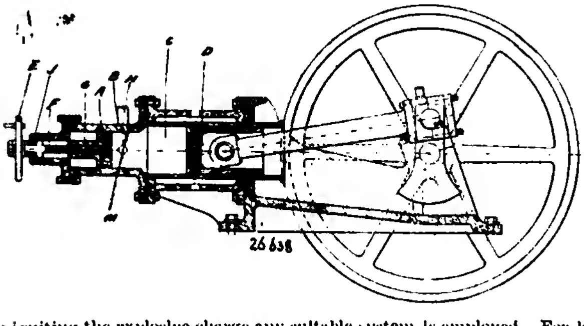
26,636. Gas and Petroleum-Engines and Motors. Robert Owen Allsop, 37, Norfolk Street, Strand, London. November 24th, 1896.

In the compression space or combustion chamber is provided a piston or plunger, A, which, being advanced or withdrawn, diminishes or increases the cubical contents of the space into which the explosive mixture of gas or oil vapour and air is compressed in the return compressing stroke of the motor piston.

The compression chamber employed in carrying out this invention may be water jacketed in gas or petroleum engines, and in the latter also may be employed as and for the purposes of vaporisation of the oil. The space at the back of the adjustable piston or plunger may by suitable means be water-jacketed if desired.

A, B, C, and D are respectively the adjustable piston or plunger, the compression or explosion chamber, the cylinder, and the motor piston. The compression chamber, as shown, is a separate bored casting bolted to the cylinder by suitable flanges. The adjustable piston is advanced or withdrawn by revolving the hand-wheel, E, which operates the screwed spindle, F, working in the screw threads cut in the bored boss, G, forming a continuation of the adjustable plunger or piston, A. Suitable metal piston packing rings are used to check the escape of gases. J is a casting against which the flange of the screwed spindle, F, bears, and is bolted to the casting forming the compression or explosion chamber. J is bored to receive G. At M is a valve timing the ignition of the charge of compressed gas or oil vapour and air. N is the ignition tube with Bunsen or other suitable burner.

FIG. 2.



In igniting the explosive charge any suitable system is employed. For large stationary gas and petroleum-engines a hot tube ignition with a timing valve is used; for locomotives and road motors and the like, preferably one or another suitable systems of electrical ignition. Either hot tube ignition or electric ignition are well suited for ignition in carrying out this invention.

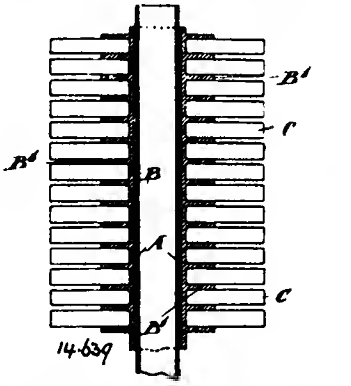
This invention affords a ready means of facilitating the starting of engines and motors for gas or petroleum-driven locomotives for rail or road or for motor-cars or motor-cycles, by lessening the compression when pulling round the fly-wheel by hand.

This invention also affords a ready means of regulating the speed and power of engines and motors. Advancing the plunger towards the motor pistons will increase the initial compression of the explosive mixture and consequently the power of the explosion. Withdrawing the plunger in a direction away from the motor piston will conversely diminish the compression and consequently the force of the explosion will be less. Thus the engine becomes differentially regulated, and its power and speed elastic and variable at will. Moreover, in the use of this invention it is not necessary, in regulating the engine, to interfere with or alter the actual amount and proportion of gas or oil vapour supplied, and thus the delicate adjustment of gas or oil vapour to air need not be disturbed. Several modifications are described.

14,639. Apparatus for the Production of Electricity from the Waste Heat of Gas, Steam, or other Heat Engines. Herbert John Dowsing, 24, Budge Row, London, E.C. July 2nd, 1896.

This invention relates to the application of appliances known as thermopiles for the direct production of electricity from the waste heat of explosive or other heat engines.

A, represents part of the exhaust pipe of the engine, B, a cylinder of porcelain, fireclay, or other suitable fire-resisting material, which is a bad conductor of electricity, and having formed therewith the flanges, B^1, between which are placed the elements, C, of the thermopile. The inner ends of these elements

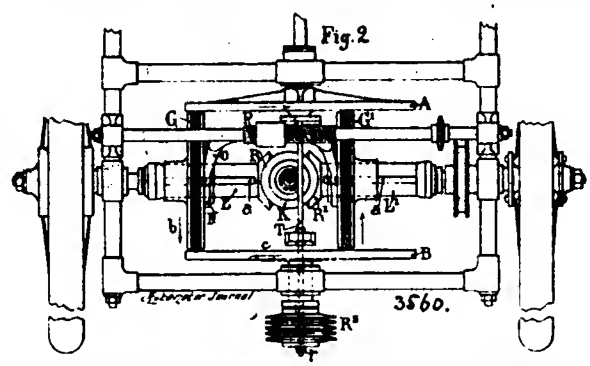


touch or are brought into close proximity with the cylinder, B, so as to be heated by the heat transmitted thereto from the exhaust pipe, A, through which the hot products of combustion pass on their way to the outer atmosphere. The outer ends of the elements, C, are freely exposed to the cooling effect of the outer atmosphere, the difference of temperature between the inner and outer ends of the elements, C, causing a current of electricity to be generated in them in the manner well understood in connection with thermopiles.

The arrangement of thermopile above described and shown, is given only by way of example as any other suitable arrangement of thermopile may be employed.

3,560. Driving Gear of Automotor Vehicles. Paul Auriol, 23, Rue Godot-du-Maroi, Paris, France. February 10th, 1897.

Relates, firstly, to transmitting mechanism composed of a disc, A, a disc, B, two rollers, G, G^1, wheels, R, R^1, and subordinate pinions, K, K^1, hollow shaft, I, at the end of which are mounted the subordinate pinions, E, E^1, which gear with the wheels, F, D, one of which, F, is wedged or keyed on the shaft, H, and the other, D, near the wheel of the vehicle. Secondly, of mechanism composed of the spindle frame, T, the rod, S, and springs, R^2, enabling all reaction on the shafts and frame to be overcome, and effecting the tightening



of the two discs against the rollers, G, G^1. And, thirdly, a mechanism composed of the screw, P, acting on the two arms of cross-piece, O, which, by means of the collars with ball bearings attachments, N, N^1, causes the rollers, G, G^1, to approach or to move away from the centre, which cross-piece can be operated equally well by levers as by the screw, P.

11,734. Steering of Horseless Vehicles. Maurice Le Blant, 21, Boulevard Poissonniere, Paris. May 29th, 1896.

The movable part of the fore carriage is provided with a toothed ring, with which gears a pinion mounted on the spindle of the steering handle or wheel.

Between the ring and the fixed part of the fore carriage, especially in the case of heavy vehicles, anti-friction rollers or balls are placed, such balls or rollers being guided by a circular guide plate carried by arms extending from a collar mounted on the perch bolt.

ROLLER BEARINGS & THEIR APPLICATIONS.*

As the application of rolling motion to bearings is at the present time exciting much attention, the author ventures to hope that the matter contained in the following paper will be acceptable to the members of this Association.

The subject may be divided into the following heads:—

I. The advantages arising from the application of roller bearings.
II. The requirements and details of construction of such bearings.
III. The results already obtained from roller bearings which have been applied to railway vehicles, tramway cars, and other purposes.

* Paper read at the Manchester Association of Engineers by Mr. THOMAS W. HOW, F.I.S.

I.—*The Advantages Arising from the Application of Roller Bearings.*

The principal advantages arising from the application of roller bearings are the following:—

Reduction in starting effort.
Decreased tractive effort in the case of vehicles, whether running on ordinary roads, tramways, or railways.
Decreased resistance to rotation in the case of shafts and other revolving mechanisms.
Avoidance of hot bearings and economy in lubrication.

The vital importance of reducing starting effort and tractive force to the lowest possible point is well illustrated by the amount of labour and capital which has been expended with results generally satisfactory, from an economic point of view, upon the construction of the road, railway, and tramway systems of the world. The primary object of such systems is to reduce the force necessary to accomplish the transportation of people and merchandise, and, as a consequence, to effect such transportation at the least possible monetary cost.

It is interesting to note that very early in history the advantages of rolling motion were discovered. The ancient Greeks and Romans quickly appreciated the advantages of placing heavy loads upon rollers or wheels when desirous of moving them, rather than attempt to do so by sliding them over the surface of the ground. In other words, the advantages arising from the use of rolling, as compared with sliding friction, were so obvious as to ensure universal adoption of the principle.

Having obtained such good results from the adaptation of rollers or wheels for tractive purposes, it is strange that such a long period should have elapsed before any serious attempt was made to apply the same kind of motion between the wheels and their axles in the case of wheels revolving on fixed axles, or between the axle journals and their bearings, in the case of axles revolving in fixed bearings, as had been found so advantageous when acting between the rims of the wheels and the surfaces upon which they moved, the earliest of such attempts being so far as the author is aware of quite modern date.

The importance of reducing frictional assistance both in starting and running is now fully acknowledged, and is emphasised by the many anti-friction metals and special devices for improved lubrication of axles and shafts now on the market. Whatever degree of success the best of these devices may have attained they cannot approach such favourable results as are produced by the application of properly-constructed roller bearings. With reference to this part of the question, the following extract from a paper read at the Toronto meeting of the British Association in August last, by Mr. Bayley Marshall, M.Inst.C.E., is interesting:—

"*Reduction in Starting Effort.*—The reduction in the effort required to start vehicles or shafts fitted with roller bearings as compared with those fitted with ordinary bearings is of such importance that, if it were the only advantage, it would warrant the necessary additional monetary expenditure.

"In the case of steam, electrical, or other mechanical traction, the reduction of starting effort allows of heavier trains or vehicles being controlled by the existing locomotives or other motors than can at present be dealt with, and in many cases would avoid the necessity of a second locomotive.

"In the case of electrical traction, the reduced starting effort is of almost vital importance, as not only does it effect a very considerable saving in electrical output, but also greatly reduces the serious

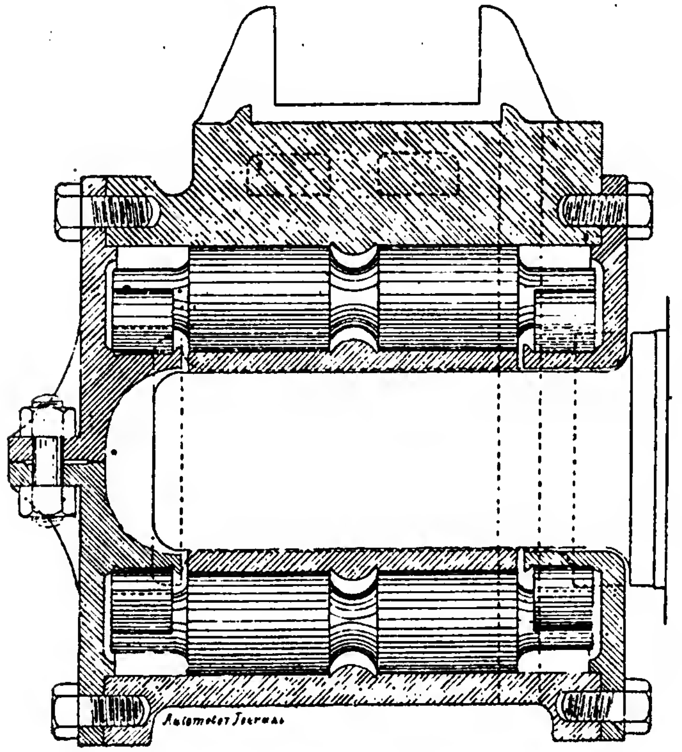

Plate 1.

rush of current through the motors at the moment of starting, which rush is due to the fact that the motors and load have to be started at the same moment, with results most detrimental to the life of the motor. If the necessary effort can be materially reduced, there will be a large economy effected under the head of 'Maintenance of Motors.'

"In the case of horse traction, the starting of the load is, as in the case of electrical traction, the most trying part of the work, and the constant effort the horses have to make to overcome this resistance when employed on heavy draught work, such as omnibuses, tramcars, drays, railway carts, &c., &c., is the principal factor in reducing their lives to the present low average. Undoubtedly, where vehicles are fitted with roller bearings, horses can perform their duties with much less distress than with vehicles fitted with ordinary bearings, a result greatly to be desired from a humane as well as from an economical point of view.

"*Decreased Tractive Force.*—Although it is not claimed that the reduction in tractive force will be so large in proportion to that in starting effort, it must be remembered that this force is in application during the whole of the time a vehicle is running on level ground or ascending gradients; this point, therefore, becomes of great importance when the total amount of work done is calculated.

"*Decreased Revolving Effort.*—This is of great economical value in all cases of heavily-loaded shafting, as careful experiments have shown that the amount of power required to drive the main and counter shafts in workshops, all the tools being idle, amounts to as much as from 50 to 83 per cent. of the power required when all the tools are in full work; these figures show that there is ample room for improvement in shafting bearings.

"Another important field for the application of roller bearings is to the main and thrust bearings of propeller shafts. The author is not aware of any reliable data as to the percentage of engine power absorbed in overcoming the friction of these bearings as now constructed; but, judging by analogy and from experiments on similar bearings, it must be very considerable.

"*Economy in Lubrication.*—This, though not of first importance, is a considerable item, seeing that a perfectly-constructed roller bearing does not require any lubrication, but only sufficient oil need be applied to prevent the rusting of the various parts."

The author thinks it is only right that he should state that Mr. Marshall's favourable opinions were chiefly founded on the results of experiments and trials made with roller bearings of the design and character hereinafter described.

II.—*The Requirements and Details of Construction of such Bearings.*

The requirements of a satisfactory roller bearing may be stated as under:—

1st. The rollers must be provided with sufficient bearing in lineal inches and be of sufficient diameter to withstand the stresses imposed upon them, and must also be made of suitable material.

2nd. The rollers must not be allowed to touch each other; they must be controlled against lateral motion, and must remain exactly parallel with the axis of the journal throughout their revolutions thereon, as any deviation from the later requirement reduces the contact between the rollers and journal to a point, and sets up a spiral movement of the whole series of rollers upon the journal. If such movement is allowed it is fatal to the good working of the bearing.

3rd. That the moving parts must be proportioned so that only rolling movement takes place between the engaged services.

4th. That the end thrust or tendency to lateral movement must be controlled not only in the case of the rollers themselves, but also of the axle or shaft in a fixed bearing, as, for instance, a railway axle, or of the bearing when revolving on a fixed axle, as does the ordinary road vehicle wheel.

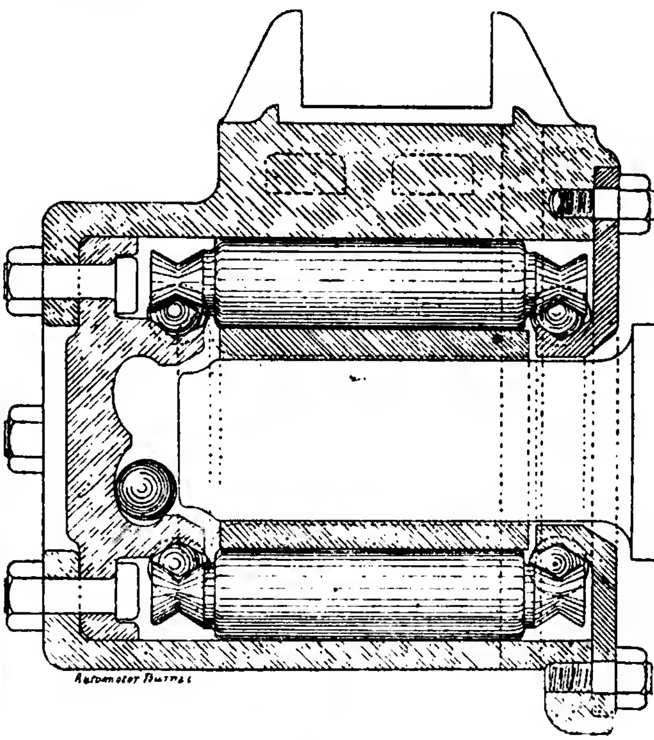

Plate 2.

5th. That the bearing must be as simple and as free from complications as possible.

6th. Dust and dirt must, as far as possible, be excluded, though their presence is not so injurious to roller as it is to ordinary bearings.

7th. If it is desired to make a commercial as well as a mechanical success of such bearings, they must be so constructed that they can be produced at reasonable cost; they must not require special attention, and must be capable of long service, with small cost for maintenance.

PLATE 3.

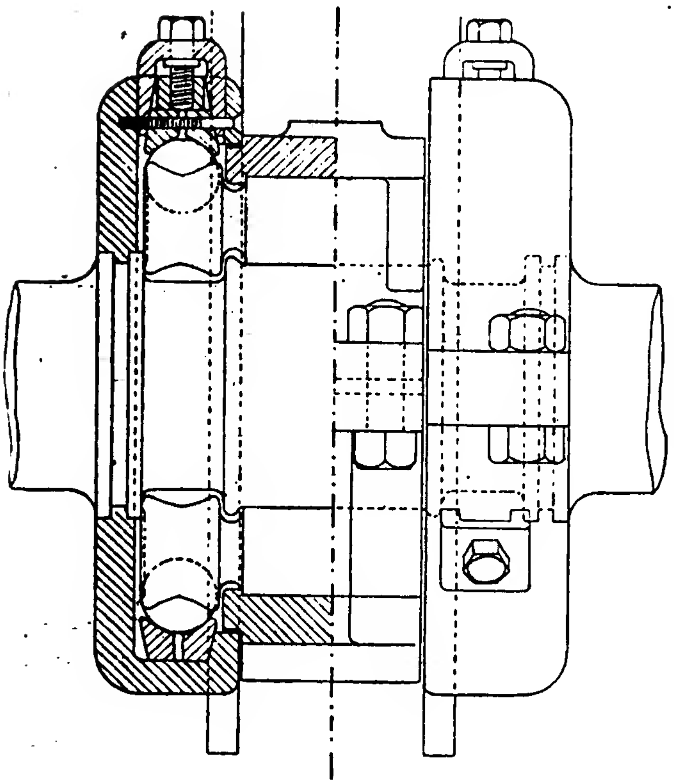

PLATE 4.

Simple as the above requirements may appear, the author believes that the only bearings at present which approach their fulfilment are those he is about to describe, and it will be interesting to state shortly the steps by which the present design was reached.

In the first attempts the rollers were spaced by subsidiary rollers as shown in Plate 1, or by balls as shown in Plate 2; one such subsidiary roller or ball being placed at each end between each pair of rollers so that in any bearing there was twice the number of subsidiary rollers or balls than of main rollers. It was found, in the first place, impossible to keep these spacers in their proper position, as there was a strong tendency for them to fly outwards, and in the second place there was nothing to prevent the whole combination taking a spiral form.

To overcome the first difficulty, floating rings were introduced as shown in Plates 3 and 4, and the results proved that a great step in advance had been made, but that the spiral action still remained. The next step was to connect the spacing subsidiary rollers or balls, or, in other words, to form them on the ends of rods, thus compelling both ends to move at the same velocity. The arrangement then became as shown on Plate 5, a form of bearing which has given

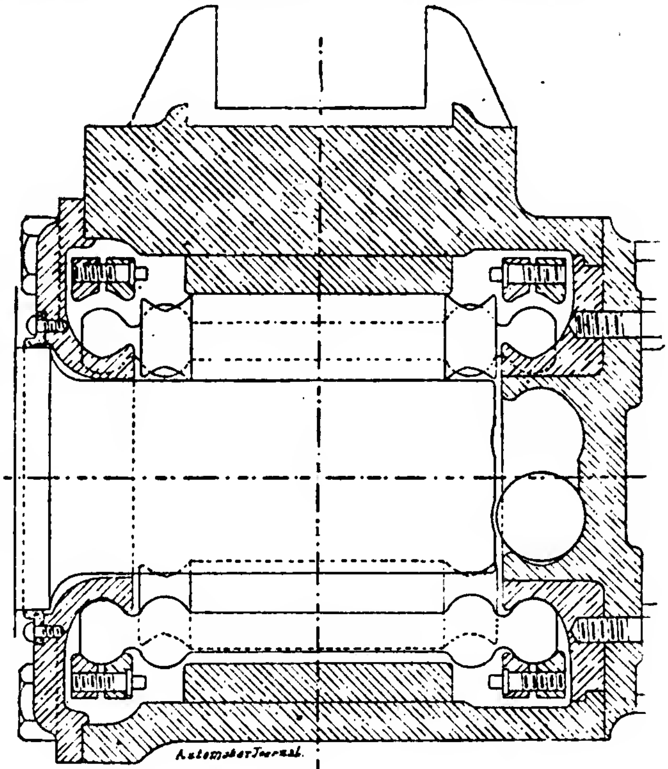

PLATE 5.

excellent results, its only fault being that it contains too many working parts, and is consequently too costly for general application. In this form of bearing, when the various moving parts are properly proportioned, there is nothing but true rolling movement. The next step was to do away with the subsidiary or spacing rollers, and to introduce a floating cage in their place, this cage being so designed that although it acts as a spacer for the rollers it does not carry any of the load. The general arrangement of the bearing then became as shown by Plate 6, and Fig. 1, Plate 7, of which Plate 6 is a cross section of the bearing, Plate 7 a longitudinal section, and Figs. 2 and 3, on Plate 7, details of the small bearing pieces which carry the ends of the rollers. This form of bearing has been applied, amongst other purposes, to "Great Paul," the big bell at St. Paul's Cathedral, London, with most satisfactory results. The next and final step was to do away with the conical points at ends of rollers and special bearing pieces in cage, and to make the rollers simple cylinders bearing on the spokes of the cage, as shown on Plate 8. This is the form of bearing recommended by the author, and is the one that has given the results set forth under heading III. It will be seen that there is only one moving part, namely, the cage, in addition to the rollers, and the only sliding friction in the arrangement is that between the rollers and their bearings on the cage, this is of very small amount, as it has only to overcome the resistance of the cage to revolution.

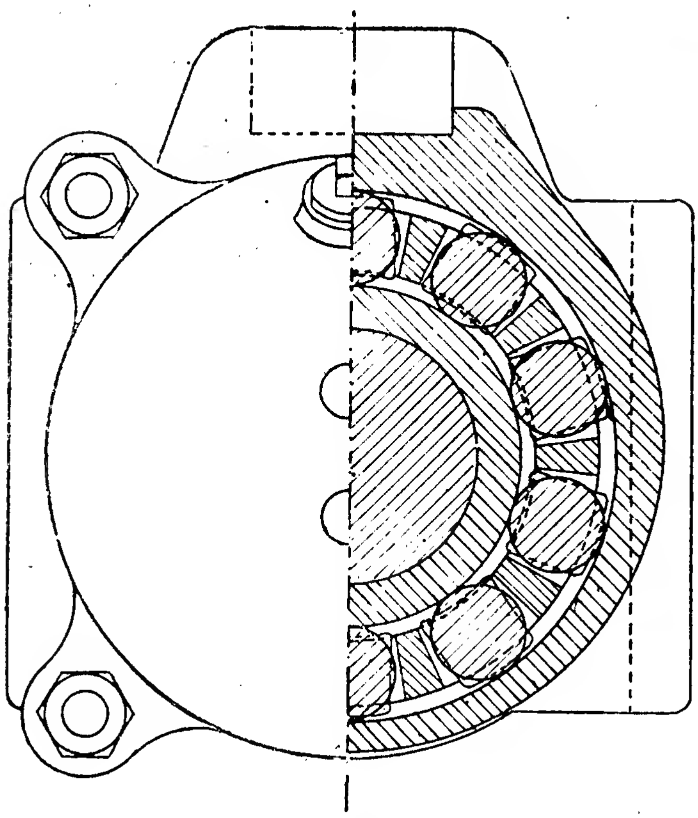

Plate 6.

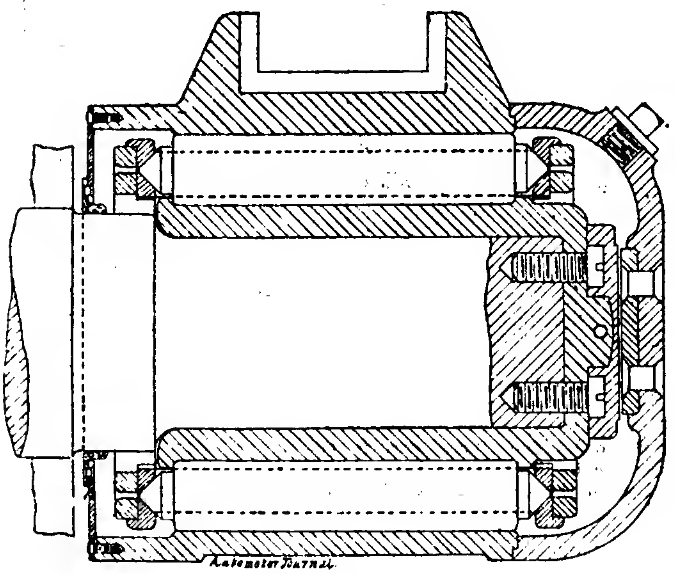

Plate 7.

It is of interest to note that in this form of bearing the speed of revolution of the cage is only about one-third of that of the journal.

The above is a short description of the process of evolution of the latest form of roller bearing.

III.—*The Results already obtained from Roller Bearings which have been applied to Railway Vehicles, Tramway Cars, and other Purposes.*

As to the results which have been obtained in practice from roller bearings:—

"For many years the only successful application of rolling motion to bearings was the well-known 'ball bearing' so universally adopted for cycles, and although these bearings have been found most satisfactory when subjected to light loads, all attempts to apply them to heavy ones have, so far as the author knows, resulted in failure, these failures arising chiefly from the balls indenting the paths or races upon which they run. Directly this takes place the balls begin to lose their friction-reducing properties. If a semicircular trough be constructed which accurately fits a ball, and after the ball is placed therein, one end of the trough is lifted until movement of the ball takes place, it will be found that the ball moves by sliding and not by rolling. This is indentation carried to its extreme limit."

Another defect in the ball bearing is that the balls are allowed to touch each other, and as the touching points of any two balls are revolving in opposite directions, there must be a certain amount of scrubbing friction between them. This is shown by Plate 9.

Roller bearings of the form which the author has described are now coming into extensive use. Considerably over 1,000 of them

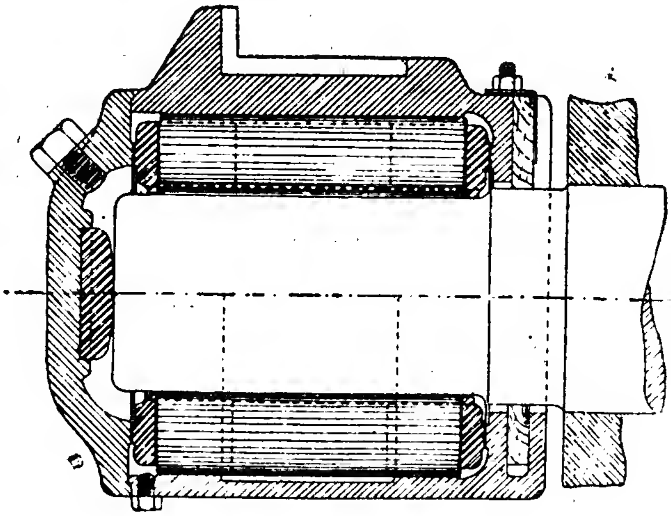

Plate 8.

have been supplied, or are in course of construction, and considering the short time they have been on the market, such results speak for themselves. The following list shows how general is the application of these bearings which have been supplied to or are in process of manufacture for many English and foreign tramways, and—

Line shafting,
Motor-cars,
Seed-crushing mills,
Furnace bottom cars for armour plates,
Hand trucks,
Engine shafts,
Cycles,
Omnibuses,
Gas traction cars,
The great bell of St. Paul's, London—"Great Paul,"
The "Monorail" Electrical Express Railway at Brussels, &c., &c.

The following are amongst the most interesting results obtained:—

Railways.

In railway vehicles fitted with these bearings the starting effort has, in many cases, been found to be as low as 3 lbs. per ton of load.

A passenger train of six carriages, fitted with roller bearings throughout, has been running for over two years between Brighton and Kemp Town, with a total mileage of over 70,000, and has shown a saving of from 12½ to 15 per cent. in the consumption of fuel, which saving has been obtained under most disadvantageous circumstances, inasmuch as the engine has to be kept in steam for about 16 hours per diem, whilst its actual running time is under seven hours.

The road between Brighton and Kemp Town is also a most trying one on account of its almost continuous curves, its constant stoppages necessitating great expenditure of brake power, and the abnormal number of points and crossings in so short a run, added to which a great portion of the line is laid with guard rails, so that the fixed charges of traction are in this case very heavy.

So well satisfied is the Brighton Railway Company with the extended trials as above-named, that orders have now been placed for roller bearings for main-line traffic.

PLATE 8A.

The Western Railway of France are fitting a complete train with roller bearings for experimental purposes, and their report will undoubtedly be of great value, as investigations of this kind are carried out with great care and skill by Continental engineers.

The Liverpool Overhead Railway made their first trials with these roller bearings some two years ago, and are now gradually fitting them to the whole of their rolling stock, as they find that since their introduction they have, with a slight modification of their motors, been enabled to run three instead of two coach trains, the extra coach being without motors, thus increasing the carrying capacity of their trains by 50 per cent.

The contention that the application of roller bearings in the case of electrical traction will show a great economy under the head of "Maintenance of Motors," has been amply borne out by the experience gained at Liverpool.

The City and South London Railway are applying these bearings to their carriages.

TRAMWAYS.

The following are the results of careful experiments made to ascertain the relative starting effort and running friction of tramcars, fitted with ordinary and roller bearings.

Starting Effort.—Tramway cars, weighing 4 tons 15 cwt., ordinary bearings, 198 lbs. or 41·68 lbs. per ton; roller bearings, 30 lbs, or 6·53 lbs. per ton—a saving of 84 per cent.

RUNNING FRICTION—GRAVITY TEST.

A tramway car, fitted with ordinary bearings and weighing 2 tons 15 cwt., was let loose from a point 56 feet up an incline, with 1 foot 6¼ inches rise. It ran down this incline and 57 feet along the level line at foot of same, or a total distance of 113 feet. The force expended was, therefore, 6,160 lbs. falling through 1·521, &c., feet, or 9,364 foot lbs. The average frictional resistance was 9,364 ÷ 113, or nearly 83 lbs., equal to 30·5 lbs. per ton. A similar car fitted with roller bearings being let loose from the same point, ran the full length of the level line available, namely, 320 feet, and had not then quite come to rest, the total distance traversed being 376 feet. The force expended was, again, 9,364 foot lbs. The average frictional resistance was 9,364 ÷ 376—24·9 lbs., or about 9 lbs. per ton of load, a saving of 70 per cent.

The following figures are of interest, and are founded on the results of actual experiments:—

Relative starting effort of a tramcar on a gradient of 1 in 20, ordinary bearings 100, roller bearings 77, saving 23 per cent.; ditto, ditto, on a gradient of 1 in 80, ordinary bearings 100, roller bearings 50, saving 50 per cent.; ditto, ditto, on a gradient of 1 in 140, ordinary bearings 100, roller bearings 39·6, saving 60·4 per cent.—results which require no comment.

Roller bearings have been fitted to many horse cars, with results most beneficial to the animals employed, and it is estimated that the use of them would so prolong the life of the horses that the reduction in their depreciation alone would show a saving of considerably over £10 per car per annum.

The Corporation of Blackpool have had some of their tramcars fitted with roller bearings, and these cars have been running on their electric tramway for over three years, and with results so satisfactory that they have applied similar bearings to all the new cars which have been constructed since the advantages of these bearings were established; and their consulting engineer some short time ago certified that at least 30 per cent. of electrical output is saved by the use of such bearings as compared with those in ordinary use.

PLATE 9.

GENERAL APPLICATIONS.

Perhaps one of the most interesting amongst the general applications of these bearings is that of the big bell of St. Paul's Cathedral, "Great Paul," which, with its headstock and other moving parts, weighs nearly 25 tons, and which gave considerable trouble when mounted on ordinary bearings. The following results are instructive:—When mounted on the ordinary bearings the bell came to rest—after the swinging effort had been discontinued—within one minute, when on roller bearings in 6 minutes 55 seconds, showing that the frictional resistance of the latter was only about *one-seventh* of the former, a result remarkably in accordance with the starting effort tests given under the head of "Tramways."

An equally satisfactory result has been obtained from four bearings fitted to the main shaft of a heavy seed crushing mill at Hull, the actual saving, arising from the alteration from ordinary to roller bearings, being at the rate of no less than £120 per annum, a saving that will repay the cost of such alteration in less than six months, and continue as an annuity for the remainder of the life of the bearings.

Two large bearings are now being manufactured for the main shaft of a large colliery ventilating fan for the North of England.

With reference to the question of heating, it is an interesting fact that there has not been a single case of a hot bearing in all the experience so far gained with roller bearings.

MAINTENANCE.

Although it is somewhat early to predict what the cost of maintaining these bearings will be, the results so far show that if they are constructed of suitable materials, it will be extremely low, 60,000 miles in railway work, and over three years in tramway work, with but very slight wear are most encouraging. It has been found that polished compressed steel is the best material for the rollers, cast steel for the cases in railway and heavy shafting bearings, and hard cast-iron for tramcar and other lightly loaded and slow-running bearings.

The demand for these roller bearings is steadily increasing, and the results obtained from their practical application in every-day use justify the author in his conviction that the experimental stage of roller bearings is now past, and that as the demonstration of their utility and economy becomes more generally known and appreciated, their success is already assured, and their universal adoption is only a question of gradual, if not of rapid, development.

With regard to cost. It is scarcely fair, perhaps, to make an absolute comparison with the ordinary axle-box bearing or plummer block at present in use, since the materials, workmanship, and working parts are essentially different. Moreover, economies in machinery and manufacture which follow a large and increasing demand, cannot fail to exercise a beneficial effect in this respect, but generally it may be said that the present first cost is from two to three times that of an ordinary bearing of similar dimensions, which longer life and the economies effected in fuel, lubrication, and cost of labour in maintenance amply compensate for in ultimate or annual expenditure.

Many of the above facts are recorded in papers read by Mr. W. Bayley Marshall before the Institution of Civil Engineers, London, and the British Association, Toronto, in May and August last, respectively, but in the author's opinion they are of such interest and pregnant with such possibilities for the future, that he hopes no apology is needed from him for bringing them before the members of this Association. They are absolute results obtained from the forms of roller bearings he has described, these bearings being, so far as his information goes, the only successful ones for heavy loads at high speeds. He thinks enough has been said to show that there is likely to be a large development in the application of these bearings in the immediate future, and he also ventures to hope that the foregoing paper will be of use to those interested in the question.

The author, in conclusion, desires to express his obligations to Mr. W. H. Woodcock, M. Inst. C.E., the engineer of the Roller-Bearings Company (Limited), for much of the information and the technical results given in this paper.

In the discussion which followed the reading of the paper, the PRESIDENT remarked that, although a roller bearing might cost more than one of the ordinary kind, this might be compensated for by a reduction in friction.

Mr. W. H. HUNTER, engineer to the Ship Canal Company, observed that they had a large number of sluices on the canal 30 feet wide each, some of them working under a differential head of 16 feet, and every one of which was worked on the roller principle with admirable results. The projectors of the Panama Canal had informed him they were going to adopt the principle of roller bearings for their sluices. Then they had on the canal a number of swing bridges, which were carried on the free roller principle. The whole secret of success in roller bearings was the avoidance of undue unit stress.

Mr. DANIELS said there was no disputing the advantages of roller bearings, and it was simply a question of getting special machinery to produce them more cheaply.

Mr. WOODCOCK, of the Roller Bearing Company, London, said the safe load depended, to a considerable extent, on the diameter of the roller. They might put a heavier load, per lineal inch, on a large roller than on a small one.

THE PARSONS' MOTOR.

AT a recent meeting of the Institute of Marine Engineers at Stratford the Hon. C. A. Parsons read a paper describing the motor which bears his name. This wonderful motor is destined to revolutionise existing practice, and those who are interested in road locomotion will find a study of this paper advantageous.

The Hon. C. A. Parsons in the course of his paper said :—The earliest notices of heat engines are found in the "Pneumatics" of Hero of Alexandria, which dates from the year 200 B.C. One of the steam or motive power engines there mentioned is the Æolipiles, a steam reaction engine consisting of a spherical boiler pivoted on a central axis, beneath which is placed a flame. The steam escapes by bent pipes facing tangentically in opposite directions, at opposite ends of a diameter perpendicular to the axis. The globe revolves by reaction of the escaping steam, just as a Barker mill is driven by escaping water. No practical or useful steam engine appears to have been made on this or any analogous principle until the year 1884, though many attempts seem to have been made on more or less crude lines; meantime the piston engine of Papin, Savery, Newcomen, and Watts has been developed during the last 200 years, and by its general use has revolutionised the means of transit, and tended to vastly increase the productive power of labour generally.

Engine for Driving Dynamos.

The want of a fast running engine for driving dynamos presented an immediate field for the application and development of a suitable steam turbine engine. The advantages of a steady running engine having no reciprocating parts, of small size and extreme lightness, were sufficiently obvious, provided that fairly economical results as to steam consumption could be realised. The highly economical results obtained from water turbines gave hopes that, provided suitable conditions could be arranged, similar efficiencies would be obtained with steam as with water, and assuming this to be possible, it would naturally follow, after taking all other losses into account, that the steam turbine would be more economical in steam than the piston engine. These possibilities, and the interest of applying a practically new method for motive power purposes, led us to build an experimental engine of 10 H.P., coupled directly to a dynamo. For practical reasons it was, however, necessary to keep the speed of rotation of the turbine as low as possible, and also to construct the dynamo to run as fast as possible, so as to couple the turbine directly to it, and in order to obtain the necessary conditions for steam economy the turbine was made what is called compound, or, in other words, a series of successive turbine wheels were set one after the other on the same spindle, so that the steam passing through them one after the other, the fall in pressure being spread over the series of turbines, should be gradual, and the velocity of the steam nowhere more than was desirable for obtaining a high efficiency for each turbine of the series.

The Turbine Motor.

The turbine motor consists of a cylindrical case with rings of inwardly projecting guide blades, within which revolves a concentric shaft with rings of outwardly projecting blades. The rings of blades on the cylinder nearly touch the shaft, and the rings of blades on the shaft lie between those on the case and nearly touch the case. There is left between the shaft and the case an annular space, which is fitted with alternate rings of fixed and moving blades. Steam passes first through a ring of fixed guide blades by which it is projected in a rotational direction upon the succeeding ring of moving blades, imparting to them a rotational force; it is then thrown back upon the succeeding ring of guide blades, and the reaction increases the rotational force. The same process takes place at each of the successive rings of guide and moving blades. The energy to give the steam its high rotational velocity at each successive ring is supplied by the drop in pressure, and the steam expands gradually by small increments. In a moderate size turbo-motor there may be from 30 to 80 successive rings, and when the steam arrives at the last ring the expansion has been completed. On the left side of the steam inlet are the dummy or rotating pistons, which are fixed to and rotate with the shaft. On their outsides are grooves and rings which project into corresponding grooves in the case. By means of the thrust bearing of the motor, the longitudinal position of the shaft is adjusted, and grooves and projecting rings kept nearly touching, so as to make a practically tight joint. The object of these pistons is to steam balance the shaft and relieve end pressure on the thrust bearing. I give herewith a drawing * of a 350 kw. Turbo Alternator, 13 of which size are now at work in the London stations. With compound condensing turbines a steam efficiency comparable with the best compound or triple expansion condensing engines was at length reached, and it was then resolved to test the application of the compound turbine to the propulsion of ships, for which purpose it seemed well suited, provided that as good an efficiency could be obtained from fast running screw propellers as with ordinary ones.

The "Turbinia."

In January, 1894, a syndicate was formed, and a boat was designed for this purpose. The "Turbinia," as the boat is named, is 100 feet in length, 9 feet beam, and 44½ tons displacement. The original turbine engine fitted in her was designed to develop upwards of 1,500 actual H.P., at a speed of 2,500 revs. per minute. The boiler is of the water-tube type for 225 lbs. per square inch working pressure, with large steam space, and large return water-legs, and with a total heating surface of 1,100 square feet, and a grate surface of 42 square feet. Two firing doors are provided, one at each end. The stokeholds are closed, and the draught furnished by a fan coupled directly to the engine shaft. The condenser is of large size, having 4,200 square feet of cooling surface. The circulating water is fed by scoops, which are hinged and reversible, so that a complete reversal of the flow of water can be obtained should the tubes become choked. The auxiliary machinery consists of main air pump and spare air pump, auxiliary circulating pump, main and spare feed pumps, main and spare oil pumps, also the usual bilge ejectors; the fresh-water tank and hotwell contain about 250 gallons. The hull is built of steel plate, of thickness varying from $\frac{3}{16}$ inch in the bottom to $\frac{1}{16}$ inch in the sides near the stern, and is divided into five spaces by watertight bulkheads. The deck is of steel plate, $\frac{1}{16}$ to $\frac{1}{8}$ inch in thickness. The approximate weights are:—Main engines, 3 tons 13 cwt.; total weight of machinery and boilers, screws and shafting, tanks, &c., 22 tons; weight of hull complete, 15 tons; coal and water, 7½ tons; and total displacement, 44½ tons. Trials were made with screws of various patterns, but the results were unsatisfactory, and it was apparent that a great loss of power was taking place in the screw. Owing to the cavitation of the water, the matter was then thoroughly investigated theoretically and experimentally, and it was finally determined (as the best course to overcome the difficulty) to subdivide the turbine motor into several separate compound turbines. Consequently the single compound turbine engine was removed from the boat and replaced by three separate compound turbines, directly coupled to three screw shafts, working in series on the steam, the turbines being the high pressure, intermediate, and low pressure, and designed for a complete expansion of the steam of hundredfold, each turbine exerting approximately one-third of the whole power developed, the three new screw shafts being of reduced scantling. By this change the power delivered to each screw shaft was reduced to one-third, while the division of the engine into three was favourable to the compactness and efficient working of the turbines. The total weight of engines and the speed of revolution remained the same as before. The effect on the screws was to reduce their scantling, and to bring their conditions of working closer to those of ordinary practice. The thrust of the propellers is balanced by steam pressure in the motors. At all speeds the boat travels with an almost complete absence of vibration, and the steady flow of steam to the motors appears to reduce the liability to priming; at any rate, no sign of this has yet occurred with ordinary Newcastle town water. No distilling apparatus has yet been fitted. The boat has been run at nearly full speed in rough water, and no evidence of gyroscopic action has been observable, though such a result would be anticipated from the known small amount of these forces under actual conditions; indeed, the "Turbinia" has so far proved herself an excellent sea-boat.

Advantages over Ordinary Engines.

The advantages claimed for the compound steam turbine over ordinary engines may be summarised as follows:—(1) increased speed; (2) increased economy of steam; (3) increased carrying power of vessel; (4) increased facilities for navigating shallow waters; (5) increased stability of vessel; (6) increased safety to machinery for war purposes; (7) reduced weight of machinery; (8) reduced space occupied by machinery; (9) reduced initial cost; (10) reduced cost of attendance on machinery; (11) diminished cost of upkeep of machinery; (12) largely reduced vibration; and (13) reduced size and weight of screw propellers and shafting. For the purpose of going astern a small reverse turbine is used. This turbine has hitherto been of an inefficient form, and has constituted a part of the low-pressure motor; the power consequently that has been developed has been very small, and has given an astern speed of three knots. A powerful reversing motor is, however, now being fitted of similar construction to the ahead motors; its weight is three-quarters of a ton, and it is estimated that the astern speed will then exceed 10 knots. The turbine will be permanently connected to the central propeller shaft, and its casing will be connected to the condenser, and the amount of power spent in turning it when going ahead will be insignificant. In June last the "Turbinia" steamed from the Tyne to Harwich at the average speed of 12 knots, and from Harwich to Cowes at the average speed of 16 knots. During and after the week of the review she was run at speeds up to 34½ knots, estimated from the curve of steam pressure and speed, and ample steam is provided by the boiler at the highest speeds hitherto reached.

Results of Trials.

In April a series of trials were made by Professor J. A. Ewing, and the following paragraphs are extracts from his report, which comprises, I believe, the most complete set of investigations made on the working of a small fast vessel:—

"The mechanical friction of the turbines is particularly small, and the work spent on friction is not materially increased by increasing the range of expansion. This allows the steam to be profitably expanded much farther than would be useful or even practicable in an engine of the ordinary kind. Apart from questions of friction, the addition of weight and bulk to allow for this extended expansion would be enormous in the ordinary engine; in the turbine it is very moderate. Steam is expanded nearly two hundredfold in the "Turbinia," and this is accomplished with engines which are much lighter than reciprocating engines of the same power, although in these the expansion would be much less complete. Rough weather was met with in some of the trials, and I had the opportunity of seeing that the "Turbinia" is for her size a good sea boat. The machinery worked with perfect smoothness, the screws did not race, and the bearings remained perfectly cool throughout. From first to last during the whole of the trials there was no hitch whatever or difficulty of any kind in the action of the turbines. Some 20 trial runs in all were made under various conditions as to speed, the range of speeds tested extending from 6¾ knots to 32¾ knots. Full speed trials were made on 10th April, the boat having then been in the water for fully a fortnight. Two successive runs on the measured mile, in opposite directions, in smooth water and at the slack of the tide, gave the following data:—

	1	2
Time on the mile	109¾ secs.	110 secs.
Corresponding speed in knots ..	32·79	32·73
Mean speed in knots	32·76	
Revs. per minute of high pressure and intermediate shafts	2,230	
Revs. per minute of low pressure shaft ..	2,000	
Steam pressure in boiler by gauge	210 lbs. per sq. in.	
Steam pressure on admission to high pressure turbine	157 lbs. per sq. in.	
Greatest pressure in stokehole, by water gauge	7¼ in.	

"The speed reached during this trial, 32·76 knots in the mean, is, I believe, the highest recorded for any vessel. It is greatly in excess of the speed hitherto reached in boats so small as the "Turbinia." It is clear, then, that the exceptional speed developed in the "Turbinia" has been achieved without sacrifice of any economy, and that the substitution of turbines driving high speed screws in place of reciprocating engines driving screws of much more moderate speed is not attended with increased consumption of steam so far as fast running is concerned."

Turbines for Large Vessels.

In conclusion, the application of the steam turbine principle to fast ships in general, including passenger vessels, Atlantic liners, and ships of war, would appear to present no special difficulties. It may be said, generally speaking, that the larger the scale on which the engines are made the simpler is the construction and the higher the steam efficiency and the lower the speed of rotation. In the sizes hitherto constructed, the largest being the engines of the "Turbinia,"

E

* We hope to reproduce this in our next issue.—ED.

tbis has been found to be tbe case. In applying turbine engines to a large passenger vessel or warship of, say, 30,000 I.H.P., probably four screw shafts with two screws on each shaft would be adopted; each of tbe four shafts would be driven by one compound turbine at a rate of between 400 and 700 revs. per minute, and the turbines would consist of the high pressure, the intermediate and two low pressure, each turbine developing approximately one-quarter of the total power. The screw propellers would be about one-half the diameter of ordinary twin-screw propellers, and the aggregate blade area would approximate closely to ordinary practice. With such engines the consumption of steam per propulsive horse-power would probably be less tban that found in the mercantile marine, and considerably less than that found in war-vessels, where space and other conditions must necessarily be considered. Tbere is also no limitation in steam pressure in the case of turbines other tban those imposed by the boilers, and it is probable that in conjunction with water-tube boilers higher pressures than those at present usual would be generally adopted. With turbine engines in passenger vessels there would arise no questions of vibration from machinery or propellers, and in the event of one screw shaft or one motor becoming disabled, the one affected can be more readily taken out of action tban is tbe case with ordinary engines, and the parts being lighter, can be more easily dealt with by the staff on board; thus the liability to serious breakdown is considerably reduced.

THE "SCOTTE" SYSTEM.

We are in receipt of the following letter from the Director of the "Société des Chaudières et Voitures a Vapeur Système Scotte":—

Monsieur le Directeur de L'Automotor and Horseless Vehicle Journal, 62, St. Martin's Lane, Londres, W.C.

Je viens de recevoir le No. du 15 Octobre de votre Journal. Voulez vous me permettre de compléter les appréciations formulées par votre correspondant relativement au fonctionnement de notre train à marchandises pendant le Concours des Poids Lourds.

Étant donné le profil extrêmement accidenté des parcours ou l'on rencontrait des rampes de 14 per cent., nous n'avons transporté au maximum que 5½ tonnes de poids utile: mais il faut admettre que ce ne sont pas là les conditions normales du roulage.

Sur bonnes routes, en palier ou faibler rampes, c'est à dire ne dépassant par 4 per cent., nos machines peuvent convoyer à la vitesse de 7 à 8 kilomètres à l'heure de 10 à 12 tonnes de *poids utile.*

The Scotte Tractor and Trailer.

Par ce même courrier et sous pli séparé je vous adresse deux phototypies représentant notre tracteur porteur avec sa charge réelle.

Dans vos "Notes du Continent" je relève qu'à la suite de nos essais dans le Luxembourg, la douane nous réclame 6000 francs pour la rentrée en France de nos machines. Permettez moi de vous faire remarquer que nos trains étant construits à Paris peuvent sortir de France et y rentrer absolument en franchise.

Veuillez agréer, Monsieur, mes salutations empressées.

Paris, *Octobre* 18.

[We have pleasure in reproducing the photograph herewith.—Ed.]

Death of a well-known Carriage Builder.—*Le Guide du Carrossier* notes the death, at the early age of 55 years, of M. Basile Dimitri-Markoff, of Moscow, Russia. M. Markoff was well known and bighly honoured in Moscow and Paris. He was wealthy, and the head of a great plant devoted to carriage building. He was urbane, genial, and his broad ideas led to the establishment of amicable relations between the members of the craft in tbese two cities. He was an admirer of France and of the French people. It was his habit to spend two or three months of each year in Paris or at French watering places. Lately he decided to remove to Paris to reside permanently, but after a return to Moscow recently be fell ill and died. He was the recipient of distinctive French honours. He carried the ensigns of tbe orders of St. Stanislaus and St. Vladamir, and was to have been decorated with the red ribbon, Legion d'Honneur, at the coming Paris exposition of 1900. Last year he was nominated a member of the jury at the Nijni-Novgorod Fair, where be rode in the Emperor's sleigh, wbich, in Russia, is regarded as a great honour. M. Markoff was a devoted Christian, and a member of the Russian (Greek) Church, and lived close to the Golden Rule, a tribute accorded him by all who knew him.

A New Electric Motor Vehicle.—Mr. T. Parker and several gentlemen connected with Messrs. Parker (Limited), of Wolverhampton, in addition to a number of distinguished visitors, attended the works in Wolverhampton, on October 27th, baving been conveyed there from tbe station in Mr. Parker's new motor-car. The main object of the visit was to test tbe capabilities of this electric motor, which was in every way satisfactory. We understand tbat Mr. Parker, when on his motor-car trips, has had a good deal of trouble with small boys, who, not satisfied with hanging on behind, have thrown sticks and stones into tbe mechanism whilst the car has been running.

RESISTANCE OF VEHICLES IN ROUNDING CURVES.

MR. HENRY SIMPSON, writing to *The Engineer* on "The Elements of Train Resistance," gives the subjoined formulæ, which, although representing what occurs on railroads, is equally applicable to steam-tractors on common roads hauling a string of wagons. In the course of his letter, Mr. Simpson says:—

"Most enginemen prefer to have the longest and heaviest vehicles near their engine, because, they say, the heavy wagons 'pull so hard' when near the break van. I cannot see that this can possibly be so on a straight road, and I will endeavour to show that even on a curved road the obliquity of the draw-bar pull cannot have a very material effect. Let us assume, for the sake of simplicity, that the vehicles of a train are all of the same weight, length, and resistance, and let—,

- T = Tractive force in pounds of engine in excess of that portion which is absorbed in overcoming the resistance of the engine itself;
- R = Resistance in pounds of each vehicle;
- θ = Supplement of angle contained by any two vehicles;
- n = Number of vehicles whose resistance is overcome by the tractive force, T;

"Now, pull exerted on first draw-bar = $T \cos\theta$, and since R is absorbed in each vehicle, the pull exerted on—

$$\text{Second draw-bar} = (T\cos\theta - R)\cos\theta = T\cos^2\theta - R\cos\theta;$$
$$\text{Third ,,} = (T\cos^2\theta - R\cos\theta - R)\cos\theta = T\cos^3\theta - R(\cos^2\theta + \cos\theta);$$
$$\text{Fourth ,,} = T\cos^4\theta - R(\cos^3\theta + \cos^2\theta + \cos\theta);$$
$$n\text{th ,,} = T\cos^n\theta - R(\cos^{(n-1)}\theta + \cos^{(n-2)}\theta + \ldots \cos^2\theta + \cos\theta).$$

"Since we have assumed that the engine is just capable of pulling the n coaches, it is obvious that the pull on the nth draw-bar must just equal the resistance:—

$$\therefore R = T\cos^n\theta - R(\cos^{n-1}\theta + \cos^{n-r}\theta + \ldots + \cos\theta)$$
$$\therefore T\cos^n\theta = R(\cos^{n-1}\theta + \cos^{n-2}\theta + \ldots + \cos\theta + 1)$$
$$\therefore \quad T\cos^n\theta = R\left(\frac{1-\cos^n\theta}{1-\cos\theta}\right)$$
$$\therefore \quad T\cos^n\theta - T\cos^{n+1}\theta = R - R\cos^n\theta$$
$$\therefore \quad \cos^n\theta = \frac{R}{R + T(1-\cos\theta)}.$$

"It will be readily seen that on a straight road $\theta = 0$ and $\cos\theta = 1$, and the geometrical progression would sum 'n,' and our equation would therefore stand $T = Rn$. It will be found that in all cases θ is so small as to make $\cos\theta$ so nearly approach unity that the obliquity of the draw-bar pull may for all practical purposes be neglected. For instance, a train of 45 empty wagons is being hauled round a curve of 600 feet radius, the total resistance being 20 lbs. per ton. It will be found from the above formula that a draw-bar pull of 5,455 lbs. is necessary; whereas, if we neglect obliquity, a pull of 5,400 lbs. is necessary. The difference, 55 lbs., is so small as to be inappreciable; nevertheless, the length of a train and the position of the heaviest laden wagons are such important items in the eyes of most enginemen that I venture to draw attention to the matter, in the hope of a correct explanation being forthcoming."

Leicester Invites Tenders for Motor Dust Carts.—The Leicester Sanitary Committee invites designs and tenders for motor-vehicles for the collection of house refuse. The motive power capacity and all other particulars are to be described in a full specification, accompanied by drawings, and delivered at the office of Mr. E. George Mawbey, C.E., Borough Engineer and Surveyor, Town Hall, Leicester, addressed to the Chairman of the Sanitary Committee, by January 31st. The loaded wagons would have to ascend an incline of 1 in 20, turn in a limited space, back and tip over a beam about 14 inches high by 12 inches in width, and when empty descend a road having a gradient of 1 in 15. The committee do not bind themselves to accept any proposal, and firms tendering must do so at their own cost, no fees being allowed for the preparation of drawings, &c.

REPORT OF THE MANCHESTER DEPUTATION ON ELECTRIC TRACTION.

THE following is a brief report of the deputation recently appointed to visit the Continent on the results of inspection of Continental stations:—

The object of the inspection was to ascertain the latest Continental practice in electric lighting, and to learn the extent to which electric traction was used, and the various methods by which it was applied, and especially, if possible, to ascertain how the problem of supplying current for both lighting and traction was dealt with.

One result of the investigation is to show that electric traction is fast superseding all other means of hauling trams. Wherever electric traction has been introduced on a small scale, the system is being largely extended, and the use of horses is being entirely abandoned. Electric traction is not only preferred to horse traction, but to all other forms of mechanical propulsion; even the Serpollet steam system in use in Paris, and which appeared so promising, is being abandoned in favour of the electric system. The essential elements common to every system of electric traction are an electric generator driven either by steam or water-power, and an electric motor fixed upon the tramcar geared to the axle of the wheels and causing them to revolve; the difference between the various systems of electric traction is comprised in the various ways of establishing the connection between the generator and the motor. The most direct and simplest method consists in connecting one pole of the generator to the tram lines, and the other to a wire suspended over the middle of each track, and carried on insulated supports. This system is known as the overhead trolley system. Next in order of simplicity and directness comes the underground conduit system. In this, each pole of the generator is connected to an insulated conductor carried in a concrete culvert beneath the roadway. Connection with both conductors is established by means of a contact-making device known as a "plough," which enters the culvert through a slot running longitudinally in the same direction as the tram lines. The third system is as simple as either of the two preceding ones, but it is less direct. It consists in charging secondary batteries or accumulators from the generator, which accumulators are fixed on the car, and afterwards give out current to the motor on the car. The electrical energy is thus stored in the accumulators, and no direct connection is necessary between the generator and the motor. The fourth system is that known as the closed conduit system. In this, one pole of the dynamo machine is connected to the rails, and the other is connected in succession to a series of metal plates between the tram lines, the connection being established automatically by the car as it moves onward. This system is as direct as the trolley or slot system, but it is much more complicated, and is very liable to become deranged.

All systems of electrical traction fall broadly under the four heads named above, but there are endless differences in detail. Thus with the trolley system, the overhead wire may be supported on posts fixed either in the middle of the roadway or at the side, arms projecting from the posts over the tracks; or it may be carried on wires, known as span wires, stretched across the track and attached either to the buildings or to two posts without arms. The wire may be fixed over the centre of the track or near one side, the latter being known as the side trolley system. Contact may be made with the wire either by means of a wheel, known as the trolley wheel, carried at the end of a long arm fixed on the roof of a car, or by means of a metal bow, also carried on the top of the car.

Again, in the underground slot system, the slot may either be at the side, one rail forming one side of the slot, or it may be midway between the two rails of each track, a third line of metal being thus necessary for each track.

In the accumulator system the batteries may be removed from the cars for charging, or they may be left in the cars. In certain cases, the accumulator system is combined with the trolley system, and the accumulators are charged from the overhead wires in those portions of the city where it is fixed, while the electrical energy so stored in the accumulators is used to run the cars over the lines in that portion of the city where overhead wires are not allowed.

Comparing the advantages of the various systems, there can be no question that the overhead trolley system is by far the cheapest to construct, costs less for maintenance than any other system, is the simplest to operate, and the most easily repaired. It is much less liable to interruption than either the underground slot system or the closed conduit system.

The accumulator system is extremely reliable, but the expense attendant on its introduction throughout the whole of the system of tramways is prohibitive, while if it be adopted for certain portions of the city, the working expenses are largely augmented on account of the great weight of the batteries having to be hauled over the whole of the lines, whether the accumulators are furnishing current or not.

The underground slot system, though as simple to work as the overhead trolley, is very much more expensive, and possesses the serious disadvantage that it entails an entire cessation of traffic over the portion of line being converted for at least three weeks during its construction. The closed conduit system, though very attractive in theory, is not at present sufficiently developed to admit of its adoption being recommended, as it is not capable of dealing with heavy traffic, is liable to fail, and may give rise to shocks fatal to animals, and unpleasant to human beings.

Inquiry and observation show conclusively that on the Continent, wherever possible, the overhead system with either trolley or bow is employed. Other systems are only resorted to when the overhead is forbidden from æsthetic considerations. These considerations doubtless have weight when streets such as the principal streets of towns like Paris or Berlin are in question; but in the case of a great commercial city like Manchester, where cheap transit is a paramount consideration, and where an interruption of the heavy traffic would be fraught with disastrous consequences, there appears no necessity to insist upon the streets being kept absolutely free from overhead wires.

Where the tram lines are laid, steel posts should be erected on each side of the street with arc lamps fixed on same.

That the steel posts should be prepared to receive cross span wires to carry the overhead trolley wires if the overhead system is adopted in Manchester.

In the streets where there are no tram lines, the arc lamps to be suspended in the centre of the streets and carried by span wires. These span wires to be fixed by rosettes to the sides of the buildings if permission can be obtained from the tenants and landlords, and if the permission cannot be obtained, steel side posts be erected, and the span wires be carried from them.

Generating Stations and Installations.—The deputation were much impressed with the manner in which the electric installations in the various cities had been carried out. The workmanship and design of the engines and electric appliances were extremely good, and silent working and steady running seemed to be the order of the day. It was evident that cleanliness of machinery and buildings were made a special object of the management.

THE COLUMBIA MOTOR-CARRIAGES.

THIS vehicle is manufactured by the Pope Company, of Hartford, U.S., and its general appearance is shown in Fig. 1. As will be seen, it is an electrically-propelled four-wheeled carriage, having seating capacity for two persons.

The body consists of a box in which is carried the battery of accumulators, the front part of the box forming the seat, and protection is given by fitting a light hood. The wheels are of the bicycle pneumatic-tyred type, with ball bearings. The body is carried by an ingenious and elaborate system of springs, while the front axletree is made something like a bowstring girder of light tubing, and forms a very rigid, strong, yet light support. The rear axletree, together with the motor, differential gear, &c., is shown in Fig. 3. The motor is of the Lundell type, and is of two H.P. rated, but can be overloaded to twice this without appreciable heating.

FIG. 1.—THE COLUMBIA ELECTRIC CAB.

Fig. 4 shows the battery and system of driving and controlling. The battery consists of 40 cells contained in four groups, 10 in each. Its capacity is 70 ampère hours, with a maximum discharge of 35 ampères. Under ordinary conditions of city traffic, running on asphalte, a speed of 12½ miles can be obtained with a discharge rate of 18 ampères. The efficiency of the system is stated to be 72 per cent., that is when discharging at the rate stated, 1⅜ H.P. are developed on the wheel rim. The connections are so arranged with a watt meter that when the charging current enters the "full" position on the dial it indicates that slightly more energy has gone into the battery than was taken out. Two small contacts, after the manner of the ordinary electric alarm clock, are provided at the "full" position, so that when the finger reaches this point the circuit is completed through the electromagnet on the cut-out which actuates the armature and permits of the main switch of the carriage being thrown out. Thus, by simply inserting the charging plug in the carriage and closing the main switch, no attention whatever is required until it is desired to next use the carriage. The recording watt meter is of a special type made by the General Electric Company.

The reversing switch shown is not put in the controller on Columbia carriages, for the reason that in some cases it is possible for an excited person during an emergency to quickly draw the controller from full speed ahead to backing. This would be liable to cause serious results, and in the Columbia carriages a special reversing switch is provided which is operated by the foot, and which makes it practically impossible for an unthinking or careless person to reverse the current in the motor when the carriage is going at full speed ahead.

The emergency switch is a small plug placed conveniently near the seat; an operator can always pull it out in case of any accident to the motor, which would prevent its being stopped.

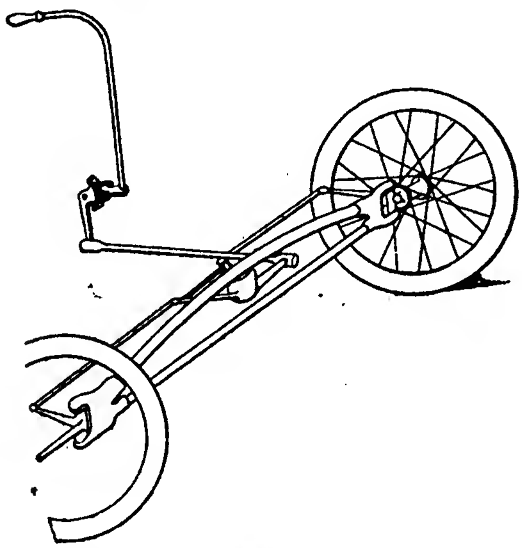

FIG. 2.

All battery connections, and, for that matter, all connections throughout the carriage which have to be manipulated in any way, are made of two different sized holes, all of the positive holes being the larger. Thus no negative plug can be entered in a positive hole, nor any positive plug entered in a negative hole; by this means it is almost impossible to make any mistakes in forming up connections.

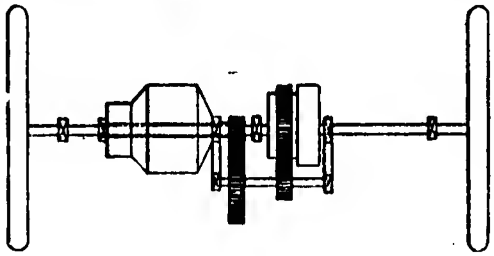

FIG. 3.

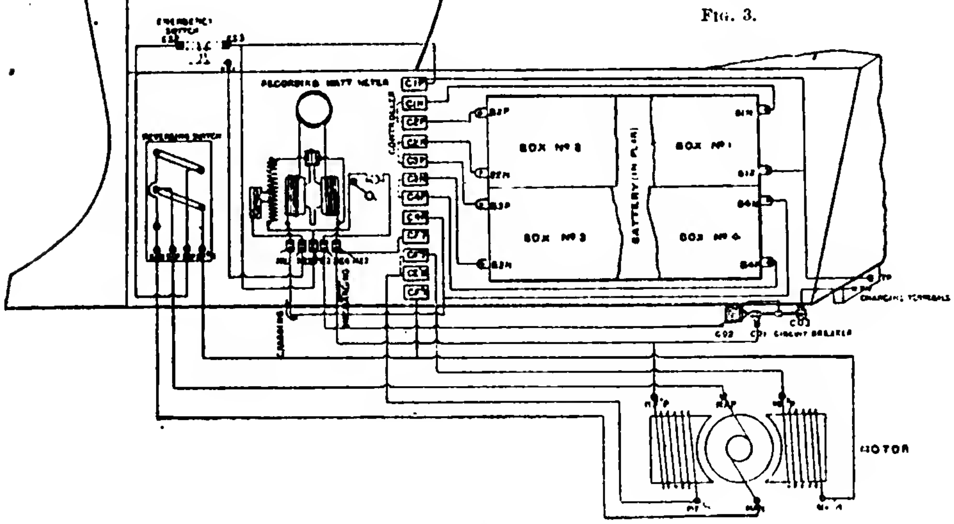

FIG. 4.

The carriage weighs about 1,700 lbs., of which 850 lbs. are accounted for by the battery. The cost of recharging is about 50 cents., and the energy suffices for a run of 30 miles on good roads at a speed of 12½ to 15 miles per hour. The cells are stated to stand wear remarkably well, one set having run 2,300 miles without deterioration. In design, appearance, and finish the Columbia motor-car is all that can be desired, and reflects credit upon the Pope Company.

MOTOR-CARS AND MAIDSTONE.

MAIDSTONE and some other towns have lately been "afflicted" —this is, we think, the orthodox word—with typhoid. In plain English, Maidstone is, like so many county towns, rather indifferently governed, and hence the people have dilute sewage given them to drink, and thereby suffer from the existence of typhoid and other filth diseases. For the sufferers we have every sympathy; and we trust that after this lesson the electorate will do their duty, and free themselves from the government of those whose first duty, in many cases, consists in maintaining abuses and privileges, and who steadily set their faces against progress, whether this takes the form of new waterworks, electric lighting, or motor-vehicles. Few other counties are so backward as Kent. With no manufactures to speak of, it is a county in which the influence of the Squire and the Parson is supreme, and hence, it is not surprising that bad sanitation should prevail in the houses, and that the water supply should be contaminated with sewage, and that motor-vehicles should be regarded with disfavour by the local bumbles and beadles. There are, unfortunately, many other towns like unto Maidstone, both in the quality of their water and in their local administration. It is, however, only when an epidemic breaks out that the public learns how very backward and reactionary a local governing body can be, and how very ridiculous the proposals emanating from such bodies can be. Thus, the Warwickshire County Council has, as is well known, a strong antipathy to motor-vehicles. At a recent meeting of this body, as we learn from the *Birmingham Argus*, it was stated that complaints had been received of motor-vehicles proceeding along Coventry Road, between the city of the three spires and Birmingham, at a high speed and refusing to stop, infringing the Light Locomotives on Highways Order, 1896. The Council decided to make a representation to the Local Government Board that such an alteration of the Order was necessary as would ensure the registration of all motor-cars; th
in som
number
number
that the
of the
responsible for any breaches of the Act. It is clear, says our contemporary, that the carriage people on the Council do not intend to part with their horseflesh or they would not suggest these restrictions, which will give a plying-for-hire appearance to a gentleman's private motor-car.

We do not object to the principle of registration, although we see no necessity for adopting it, and if it is necessary for motor-vehicles, it is also equally necessary for horse-drawn vehicles. We can assure the Warwickshire County Council that Acts of Parliament and Local Government Board Orders are not altered because a few selfish persons desire it, and before the alteration was made people of much more importance than those who compose a provincial county council would have to be heard. If our worthy friends in Warwickshire will mind their own business and look after their local water supply, they will exhibit a capacity for local self-government which at present they evidently lack, or they would not pass such childish resolutions, which are framed in no spirit of anxiety or desire for the public weal, but merely to gratify the selfish wishes of what are known as "carriage folk."

NAUTICAL AUTOMOBILISM.

THE THAMES RIVER SERVICE.

SOME time ago the Rivers Committee of the London County Council was instructed to consider what steps, if any, should be taken to provide London with an efficient steamboat service, and to free from toll the piers or landing-stages on the Thames in the county of London. The Committee have considered this and other references on the same subject, and the result appears in their report, in which they state that the first step to be taken "is to acquire and work the piers," a view which is in accordance with the one taken by the local authorities who have approached the Council. It is believed that the following 18 piers can be acquired without involving capital expenditure:—Belonging to Thames Conservancy—Wandsworth, Chelsea, Pimlico, Lambeth, Westminster, Waterloo, Temple, Blackfriars, Allhallows, London Bridge (Old Swan), London Bridge (Surrey side), Cherry Gardens, Tunnel, Globe Stairs, Limehouse, West India Docks, Commercial Docks; belonging to London County Council—Hammersmith. The undermentioned 10 could not, it is thought, be obtained without purchase:—Belonging to Thames Steamboat Company—Putney, Battersea Square, Carlyle, Battersea Park, Nine Elms; belonging to railway companies—Fulham (District Railway), Charing Cross (South Eastern Railway); belonging to dock companies—Blackwall; belonging to Greenwich Pier Company—Greenwich; belonging to Sir Maryon Wilson and the Thames Steamboat Company—Woolwich.

The following particulars show the Thames Conservancy's charges for the use of about 20 of their piers during the 10 years ended 1893:—

Expenditure on wages and staff	£4,887.3
Expenditure on repairs, rates, stores, &c. ..	3,815.7
Total	£8,703
Receipts for pier dues	5,572.6
Loss by the Thames Conservancy	£3,130.4
Maximum receipts (1884)	£8,029
Minimum receipts (1889)	4,274

The apparent smallness of receipts compared with the river traffic is accounted for in this way, that the money paid for the tolls is not the statutory charge for actual calls but for sums paid under agreement between the steamboat companies and the Conservancy. The Conservancy, it is pointed out, have statutory power to charge up to sixpence per call of each boat at each of their piers, and it is estimated that for a winter service of 15 minutes' interval and a summer one of 10 minutes, this toll would amount to £17,000 per annum. Additional charges are made by the Conservancy for the location of piers which do not belong to them, amounting to £327 10s., and there are charges for annual rental at other piers, not owned by the Conservancy, which reach a total of £3,850.

It is explained that there is reason to believe that the Thames Conservancy are willing "to arrange with the Council to facilitate the traffic on the Thames by transferring to the Council the charge, regulation, and maintenance of the existing piers belonging to them, but this concession, to be of practical utility, would need to be accompanied by the right on the part of the Council to remove them, where necessary, from their present positions to such others as might be deemed more suitable for the river passenger traffic; and perhaps would require to be supplemented by the right to acquire such piers as are owned by others which may be found necessary for the Council's purposes.

"The possibility of a municipal steamboat service has also been carefully considered by us under the Council's reference on this subject. We have received full and valuable reports from the Council's officials in this matter. We have also received, in favour of the Council providing a municipal steamboat service for London, resolutions and petitions from the following:—A public meeting held at Rotherhithe, the London Reform Union, the London Trades Council, the Vestry of Fulham, and the Vestry of St. Margaret and St. John, Westminster.

"The matter requires further consideration, and we intend to bring up, at an early date, a recommendation to the Council on this subject, but the question of instituting a municipal service is not, we think, one that is involved in any way with the acquisition and working of the piers. We have therefore considered the question of dealing with the piers first as the best way of securing an adequate and efficient steamboat service, and of increasing communication on the river and restoring the old service of the Thames as a highway, without recommending to the Council any particular system of steamboat service at present.

"We accordingly recommend the Council to pass the following resolution:—

"'That it is desirable, in the interests of better communication, that steps should be taken to secure an adequate and convenient steamboat service on the Thames, and that with this view the Rivers Committee be authorised to approach the Thames Conservancy Board and others concerned in order to ascertain on what terms and conditions the Council could acquire the piers.'"

At the last meeting of the Council this resolution was adopted by a large majority.

MAXIM'S AUTOMOTOR.

MR. HIRAM S. MAXIM, the well known inventor, has brought out a new oil motor, of which the following is an account, taken from the patent specification:—

This invention is particularly applicable to engines for horseless carriages and for other purposes where an exceedingly light and active motor is required. Gas and oil engines are now very commonly constructed to perform what is known as the "Otto" cycle, that is to say, a cycle in which work is done only at every alternate outward stroke of the piston. Therefore in such an engine no less than four cylinders are required to perform the same number of working strokes as an ordinary single cylinder steam engine and eight separate cylinders are required to effect one revolution of the crank without a fly-wheel, which can be done with a two-cylinder steam engine, as, for example, a locomotive engine. Moreover, a gas engine performing the "Otto" cycle is capable of only very slight variation of speed. It must work at a rather high speed or not at all, and it is impracticable to provide it with reversing gear. Therefore such engines are not advantageously applicable for the purpose of a road carriage which must be able to run either fast or slow, and must be capable of being reversed at will, and of being started at any time without manual assistance.

Mr. Maxim constructs an engine with two or more working cylinders, each of which will perform work with every outward stroke of its piston. In some instances is arranged, in conjunction with one or both of the working cylinders, an air-pump, the piston of which is preferably attached to the piston rod of the working cylinder; or, in some instances, the cylinder may be so constructed that one of its ends serves as the air-pump while its other end is used as the working cylinder. It is found best to arrange that the air-pump is as far as possible from the hot cylinder.

Those familiar with the subject are aware that engines have been constructed in which one end of the piston rod has been provided with a piston working in a cylinder and propelled by the pressure of hot air or gas, while another piston on the rod has been employed for compressing the air, but in such engines the pressure in the working cylinder never exceeds the maximum pressure in the air reservoir, consequently these engines are not as economical as those using the "Otto" cycle, in which the pressure exceeds that of the compressed air in the air reservoir.

In Mr. Maxim's engine the connecting rod may be attached directly to the pump-piston so that the cross-head pin or pivot will be situated in a cool place, and consequently the piston will work better than if the said pivot were at the other end. The crank pins are set at angles of 90° from each other, and are arranged in such a manner to balance the engine as nearly as possible.

The engine works in the following manner, viz.:—Suppose it is ready for starting, the compressed air tank having a pressure of about 45 lbs. to the square inch, the valve in the air passage is opened, the compressed air enters the cylinder, and the piston is pushed forward as in a steam engine. When the piston has moved through about one-fourth of its stroke it uncovers the ignition tube, or otherwise causes the ignition of the charge of gas or vapour that has been admitted to the cylinder. At this instant a valve operates to close the communication between the compressed-air tank and the cylinder, and the charge being ignited the pressure suddenly rises to about 100 lbs. to the square inch. In some instances the cylinder is allowed to become very hot, especially where heavy petroleum is used. Its temperature may be sufficiently high to ignite the gas or oil without any special igniter, and in such cases the desired result is obtained by not injecting the gas or vapour until after the piston has travelled through about one-fourth of its stroke, thereby obtaining the same results as by igniting the charge by means of a special igniter. If very heavy oil is to be employed and the cylinder kept hot as stated, it is advantageous to use a long piston provided with packing rings at its outer end, and to keep cool only that part of the cylinder in which these rings work, while the inner end of the piston may be loosely fitted in the cylinder, and made of material which will endure a high temperature. For instance, the piston may be covered with asbestos, with or without an external covering of "platinoid," which is a mixture of wrought-iron and nickel. The end of the cylinder may also be made of the same or similar material, and heated with a Bunsen burner to a temperature sufficient to ignite the oil. But where a light petroleum is used the cylinder need not be kept at a high temperature. It can be jacketted throughout its entire length, and the charge may be ignited at about one quarter of the piston's stroke either by an ignition tube or an electric spark. As the piston moves outward it performs work on the crank and at the same time compresses the air, the two pistons being brought to a state of rest at the end of the stroke by the compressed air in the air-pump.

In an engine of this kind it is necessary that a definite quantity of inflammable material shall be introduced into the cylinder at each stroke, and apparatus is provided which so operates that the admission valve, when opened at any particular part of the stroke, will not remain open. For this purpose a device is employed, which first raises a weight, and then, by means of a tappet, releases it, so that the weight in falling strikes the valve, and by its impact opens the same, but allows it to close again immediately. In this case the oil, which should be under a pressure greater than that of the compressed air, enters the cylinder in a fine spray; or it may be volatilised, and enter the cylinder in the condition of vapour. The quantity of fluid admitted may be varied by varying the force of the blow, the length of the stroke, the force of the spring, the action of the tappet, or the size or shape of the valve. The pressure on the oil should be at least 100 lbs. to the square inch, so that it may enter with great force into the cylinder. The oil may be contained in a strong tank subject to the pressure of compressed air; or a small pump may be arranged to pump a larger quantity of liquid than is required, the superfluous oil being blown through a bye-pass at a pressure in excess of the pressure of the compressed air in the tank.

When four cylinders are employed upon the same crank shaft the engine may run either at a high or a low speed. Suppose that the engine is required to run slowly on a slight downward grade, the liquid may be shut off, and then, if the cylinder is hot, the apparatus will work as a hot-air engine, the only power developed being due to the increased volume of the air entering the hot cylinder, and whenever more power is required a larger or smaller quantity of oil can be admitted as required. The speed of the engine may be reduced by closing a valve in the compressed air passage.

If an automatic regulator or governor is required, one constructed in the following manner is employed; that is to say, a diaphragm is connected with the compressed air tank and with the oil-supply in such a manner that if the pressure in the air tank rises above the pre-determined pressure it diminishes the quantity of oil or gas introduced into the chamber, whereas if the pressure shall fall below this point an increased quantity of oil will be introduced and the heat will be correspondingly increased. In this way the quantity of oil burned can be automatically regulated according to the amount of work being performed. If the load is light the engine may work simply as a hot-air engine, whereas if the load is heavy it will work as a gas or oil engine.

Reversing the engine is effected as follows:—There are two sets of cams on one shaft arranged to actuate the induction and exhaust valves, and capable of the required adjustments; or if preferred, two shafts can be used, each one having its own special cams. When a single shaft is employed the shaft may be arranged to be pushed inwards to reverse the engine, whereas if two shafts are used they may be arranged to be turned about a common centre so that one or the other will come into its operative position according as the engine is to run forward or backward.

This engine, according to Mr. Maxim, will work at any desired speed, and under very different loads, and will work as well with a heavy as with a light load. It therefore requires very much less gearing than other forms of gas or oil engines, and may in fact be geared directly to the axle of the carriage or vehicle on which it is used. The engine may be arranged to permit one or more cylinders to be used as may be required, and can be adapted to the various conditions which affect the working of a road carriage which not only has to run on the level but also has to mount and descend steep inclines. In some instances arrangements can be made for employing the engine as an air pump and thereby retarding the vehicle in descending an incline.

The air reservoir may be of any convenient shape or size, but preferably it is constructed of strong tubing completely surrounding the engine and serving as its foundation, and in some cases as the framework of the carriage. The oil reservoir may be located at any convenient part of the carriage, and the water tanks may be arranged in such a manner that the water can be fed into the parts to be cooled and can only escape as steam, the water being employed for cooling the cylinder or the exhaust valve or both as may be required.

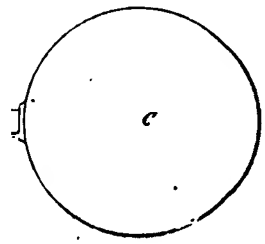
Referring to the drawings, Fig. 1 is a sectional plan of the engine adapted to be worked by charges of oil and air. Fig. 2 is a side elevation. Fig. 3 is a longitudinal section taken through one of the working cylinders and air pumps. A, A are the working cylinders and B, B are the air pumps. C is the air reservoir connected with the air pumps by the pipes, C^1, C^2, C^2. D is the crank shaft, and D^1, D^1 are the cranks thereon. E is a sprocket wheel mounted on the crank shaft and adapted to transmit motion by means of a driving chain to the axle, F, which may be the driving wheel axle of the vehicle. G, G are horizontal standards by which the working cylinders and air pumps are rigidly connected together. These standards are provided with bearings, G^1, G^1, in which the crank shaft, D, revolves and with other bearings, G^2, G^2, in which the driving wheel axle, F, revolves. The working cylinders are connected together in pairs side by side, each pair being provided with a slide valve, a, that works transversely with respect to the cylinders, and alternately opens the inlet ports, a^1, a^1, to the compressed air supply and to the exhaust passage, a^2. The slide valves are similar in construction to ordinary steam slide valves and work in valve boxes or chests, A^x, which communicate with the air reservoir or air pumps by branch pipes, C^3. At the junction of these branch pipes a throttle valve, C^4, is provided for the purpose of regulating the amount of compressed air passing to the cylinders. This valve is furnished with a stem, C^5, to which suitable lever mechanism is connected for enabling the driver of the vehicle to conveniently adjust. These slide valves are actuated by rocking shafts, a^3, having arms, a^4, a^5, the latter of which are connected to the slide valves by links, a^6, and rods, a^7, passing through suitable stuffing boxes. The arms, a^4, are connected by rods, a^8, to eccentrics, a^9, worked from the crank shaft of the engine.

For reversing the engine the sheave of each eccentric is so made that it is capable of sliding tranversely on the crank shaft.

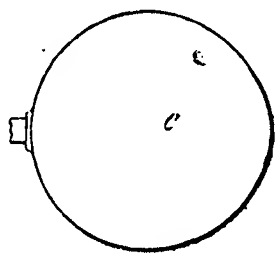
a^{13}, a^{13} are non-return valves which are situated between the slide valves, a, and the pipes leading to the air valve, C^4, these valves serving to shut off the connection between the valve box or chest, A^x, and the air pumps when the pressure within the chest, A^x, exceeds that of the air pressure.

The working cylinders are arranged in alignment with the air pumps, their pistons being coupled together by connecting rods, A^1, A^1; B^1, B^1, the former of which drive the crank shaft. The rods, A^1, B^1, are connected together by a transverse pin, a^{14}, and the head of the rod, B^1, is formed with a curved slot, B^2, for the crank pin to work in during the revolution of the cranks and the oscillation of the rods, A^1, B^1, as they alternately assume a straight and oblique position.

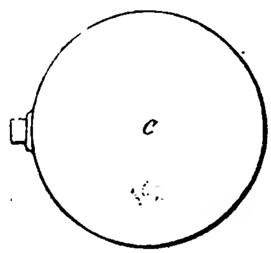
By arranging the connecting rods in this manner the pump cylinders and the working cylinders are brought closer together than would be possible if a simple rod connecting the two pistons together were



c



c'



c

employed, and yet the air pumps are kept a sufficient distance from the working cylinders to ensure the former being kept cool.

The connecting rod, A[1], is made hollow as shown, so as to contain lubricant which can flow to the crank pin. At every outward stroke of each of the air pump pistons air enters the pump from the atmosphere through the openings, b, b^1, b^2, in the piston. During the inward stroke of the pump piston the openings, b^2, are kept closed by a flexible disc valve, b^3, and the air within the pump is forced into the air reservoir through the openings, b^4, which are kept closed against the return of the air by a flexible disc valve, b^5.

The end of the working cylinder is closed by a cap or cover, A[8], which constitutes the explosion or combustion chamber. The explosive mixture of oil and air enters the chamber, A[6], through the ports, A[8]. A[9], A[10] are electric igniters which, at the required portion of the stroke of the piston, are caused to "spark" by any suitable contact device. An externally arranged lamp for heating an ignition tube, to effect the explosions, may be used if necessary. This lamp may also be used to raise the temperature of the cylinders sufficiently to cause the vaporisation of the oil charges prior to ignition.

I, I, are the oil inlet valves, each of which is arranged to be actuated by a finger or tappet, A[11], on the pistons of the working cylinders as the pistons reciprocate. The oil inlet valve is of the plunger type, and comprises an outer casing formed with a central passage, to which the oil gains access from the inlet by transverse holes. Within the passage are two valves, one being the outlet valve, and the other a non-return valve.

Extending transversely across the engine is a rocking shaft, i^{10}, having arms, i^{11}, to whose outer ends are pivotally connected levers, i^{12}. The free ends of these pivoted levers engage with the slotted heads of the plunger pump. Situated about midway of the length of this transverse rocking shaft is another arm, i^{13}, acted upon by a spring, i^{14}, which keeps the said arm, i^{13}, constantly pressed against a plunger, i^{15}, forming part of the regulator, I[1]. This regulator consists of a box or casing within which is a flexible diaphragm, upon one side of which the inner end of the plunger, i^{15}, is located. The other side of the diaphragm communicates by means of a pipe, i^{16}, with the compressed air pipe, C[3], so as to be acted upon by the pressure of the air supplied to the engine as such air passes the throttle valve, C[4]. The free ends of the pivoted levers, i^{12}, are formed with lateral inclines, i^{17}, against which the fingers, A[11], on the pistons act to open the oil inlet valves.

It will be seen that the arm, i^{13}, is subjected to two opposed pressures—that is to say, a pressure due to the spring, i^{14}, and a pressure due to the compressed air within the regulator, I[1]. Thus the rocking shaft, i^{10}, will be shifted angularly in a direction depending on which of the pressures predominates. By such angular movement the outer ends of the arms, i^{11}, will be moved up or down, and by correspondingly shifting the pivoted levers, i^{12}, will thereby vary the extent to which the inclines, i^{17}, on the pivoted levers protrude into the path of the fingers, A[11], so regulating the extent and the duration of the opening of the oil inlet valves. Thus the amount of the oil charges supplied to the cylinders by the oil inlet valves will be automatically regulated or varied by the amount or pressure of the compressed air passing the valve, C[4], from the compressed air reservoir, or pumps. By means of this governor or regulator the driver of the vehicle can, by altering the air valve, C[4], regulate the speed of the engine.

Mr. Maxim makes no less than 22 claims in connection with this motor, but the first two seem to be the more important. They are:—

1. An engine in which the first portion of the piston's stroke is effected by the pressure of air compressed before admission to the cylinder, and the remainder by pressure due to the combustion of oil or gas in such compressed air

2. A gas or oil engine adapted to work either as a hot air and explosion engine or as a hot air or explosion engine.

The specification is numbered 9,526 of 1896.

THE USE OF ALCOHOL IN PRIME MOVERS.

M. L. LÉVY, professor of distillery at Douai, has recently published in the *Distillerie Française* an interesting article in which he investigates the thermo-dynamics of alcohol and other hydrocarbons when employed as the source of motive power in an ideal motor, following the Beau de Rochas Cycle. One of the principal advantages of the use of alcohol is the total absence of that disagreeable smell that accompanies the use of petrol and other petroleum compounds in motors.

Number of Horse-power Hours theoretically produced by the Combustion of one kilogramme from the Agent.

Nature of the Agent.	Explosion in presence of the least volume of air absolutely necessary.	Explosion in presence of a volume of air double that strictly necessary.
Alcohol at 90°	3·235	3·05
Petrol	6·75	6·12
Amylic alcohol ($C^5H^{12}O + H^2O$), 83 per cent. of alcohol	4·28	3·92
Butylic alcohol ($C^4H^{10}O + 2H^2O$), 67·3 per cent. of alcohol	3·2	2·93
Distillery oil, 0·75 of amylic alcohol, 0·25 of butylic alcohol	4	6·73

From this it will be seen that from the thermo-dynamic point of view petrol has a great superiority. Coming now to the economical aspect of the question, in which one seeks to obtain the greatest amount of work at the least cost of material, the results obtained in the following table show how much work can be obtained from the combustion of one franc's worth of each of the various agents named. In the calculation the following prices obtain:—Alcohol at 90°, 30 francs per hectolitre (in bond); petrol, 0·45 franc per kilogramme; distillery oil, 0·133 franc per kilogramme:—

Number of Horse-power Hours obtained by the Combustion of one franc's worth of each substance.

Nature of the Agent.	Explosion in presence of a volume of air strictly necessary.	Explosion in presence of a volume of air double that strictly necessary.
Alcohol	9·00	8·50
Petrol	15·00	13·60
Distillery oil	30·00	27·50

From this it will be seen that it is impossible to think of replacing petrol by alcohol in small motors; pure alcohol is 60 per cent. dearer than petrol, but its use presents certain advantages, taking into consideration the cleanness and convenience resulting from a complete combustion. If, on the contrary, leaving out economy, distillery oil and alcohol are mixed, they are more easily burnt than petrol, and also they do not, like the latter, infect the air, and are capable of producing as much work, under certain conditions, as economically as petrol.

The Underground Railway and Electric Traction.—We recently commented upon the supineness of the directors of this and the District Company in adhering to steam locomotives when, as it appears to us, compressed air locomotives would offer so many advantages. Since then, a *Daily Mail* representative has interviewed an official of the Metropolitan Railway on the subject of electric traction, for the purpose of ascertaining what are the difficulties mentioned by Mr. Bell before the Board of Trade Commission, whose report was recently issued. The official interviewed said the point referred to by Mr. Bell was, he imagined, the question of finding the initial energy for starting a large number of trains simultaneously on the same section. "There are 27 stations on the circle," he said, "and to start trains from several of these at the same time would require a considerable power from the source of supply. This difficulty will, of course, be overcome eventually; but electrical traction will not be utilised on the Metropolitan system for some little time. The subject is receiving the continuous attention of the directors, but it is naturally one that demands serious consideration. As soon as a decision is arrived at a definite announcement will be made." Why does not Mr. Bell try compressed air locomotives?

DOINGS OF PUBLIC COMPANIES.

THE capital of Headland's Patent Electric Storage Battery Company (Limited) has been increased from £15,000 to £20,000 by the creation of 5,000 new shares of £1 each.

A GENERAL meeting of the Universal Electric Carriage Syndicate will be held at the London Tavern, Fenchurch Street, E.C., on December 2nd, at two o'clock, to receive a report by the liquidator (Mr. W. O. Attree) of the winding-up operations.

"SMIDDY, LONDON," is the telegraphic address of Messrs. J. W. and T. Connolly, King's Cross, manufacturers of the well-known "Ideal" rubber tyre. In this firm's advertisement in our last issue it was inadvertently printed "Smidoly." Business firms please note and alter accordingly.

THE report and accounts of the British Motor Syndicate, to be submitted at the general meeting to be held on the 18th instant, are just issued, and are published in this number. The figures are of a most remarkable nature, and as the report is only to hand as we go to press, we reserve our criticism of this extraordinary document for our next issue.

AT the meeting of the Colonial Assets and Investment Company (Limited), held on the 10th inst., reference was made to the London Electric Omnibus Company, to the effect that the former owned a one-sixth interest in the Ward accumulator, and it was stated that the London Electric Omnibus Company, which has been formed for the purpose of working this accumulator, has completed the construction of three omnibuses, but its directors have decided that until the Company has a sufficient number to run on the streets it will not commence a regular service of electric omnibuses.

A DIVIDEND of 10 per cent. has been declared by the directors of the Caledonian Motor-Car and Cycle Company (Limited), of Aberdeen. The called-up capital of the Company is just over £2,300, and the net profit from all sources from December 24th, 1896, to September 30th, 1897, being nine months and four days' trading, amount, as per profit and loss account, to £548 10*s.* 11*d.*; depreciation on the plant, machinery, fittings, &c., being 10 per cent. written off, £65 12*s.* 10*d.*; leaving a balance for division of £482 18*s.* 1*d.* This sum the directors propose to deal with as follows:—Write off the total amount of preliminary expenses, £124 12*s.* 4*d.*; pay a dividend of 10 per cent., free of income tax, on the paid-up capital of the Company, £233 19*s.*; directors' and auditors' fees, £38 8*s.*; to carry forward to next year £85 18*s.* 9*d.*

THE shareholders in Mr. Pennington's Irish Motor and Cycle Company have reason to be satisfied with the result of the liquidation which was wisely determined upon. A second cheque has been forwarded to them giving a further refund of 1*s.* 6*d.* a share to the holders of ordinary shares, leaving only 1*s.* a share of the amount which they subscribed still due. The preference shareholders have received back the entire amount, and we understand the directors are making arrangements by which, in a short time, Mr. Robert Gardner, the liquidator, will be enabled to remit the last shilling to the original shareholders. Whatever mistakes the directors made in connection with the inception of the Company, their worst enemies cannot but render them praise for the satisfactory manner in which they have seen that those who subscribed their money to the concern, upon the faith of the high characters of the members of the Board, have been properly protected, and will not be losers by their confidence.

THERE appears to have been a great number of hard words thrown about recently in regard to the affairs of the Britannia Motor-Carriage Company (Limited), resulting in the calling, on the 4th inst., at the Holborn Restaurant, of an extraordinary general meeting in compliance with the requisition of certain members holding in the aggregate 5,825 shares, or a trifle over one-tenth of the issued capital of the Company. Whether the accusations put forth against those concerned with the launching of the Company have any measure of truth in them or no, it is not for us to say, but it certainly seems to us that all the matters which this meeting was specially called to discuss would have been better left until after the ordinary general meeting of the Company, to be held on December 15th next. When this meeting has taken place and the accounts have been presented, and the progress of the concern reported upon, it should be time enough to raise questions likely to wreck the Company in the event of the reports being of the nature foreshadowed by the malcontents. At the meeting, the directors made a very good stand against the attacks of their traducers, the Chairman's proposal for the adjournment of the meeting until immediately after the annual meeting, on December 15th, being ultimately carried unanimously. We trust the directors will be able to follow up their advantage by demonstrating beyond doubt at the December meeting that the affairs of the Company are in a flourishing condition and likely to result in substantial dividends being paid speedily to the shareholders. The President, the Hon J. H. H. Berkeley, must be congratulated upon the admirable manner in which he ruled the meeting, which at first gave promise of such unpleasant developments.

THE meeting of the shareholders of the New Beeston Cycle Company (Limited), was held at Coventry on the 14th of last month, to consider the scheme of reconstruction set forth in our October issue. Mr. Rowland Hill presided, and stated that the directors had decided to take the shareholders entirely into their confidence, and had therefore given the fullest information possible. He stated that, as the meeting was aware, the vendors handed over to this Company the business assets of the successful Quinton Cycle Company, which they had previously purchased for £55,000. By the prospectus the promoters were able to legally claim a large number of vendors' shares, which established, in the Chairman's opinion, a crushing load, from which, unless relieved, it would never hold up its head. It was not long after the flotation before Dr. Iliffe and himself saw the necessity of finding some way of relieving the shareholders of this crushing weight of vendors' shares. Their endeavours had culminated in the scheme now placed before them. It was a better scheme than they ever dreamt it was possible to get, and was the result of months of anxiety and negotiation. They anticipated satisfactory results from it, and by that he meant dividends to the shareholders. They knew that their cycle business was a good one, and if fairly capitalised there should be good dividends. They had one of the finest factories in the trade, and if there was one-half the demand in England that there was in France for motor-cycles that business should pay a large dividend, even out-doing eventually the Cycle Company. The directors had been told that the present scheme was above criticism. The separation of the cycle from the motor business was considered absolutely necessary, and it was also absolutely necessary to have more working capital. On the cycle side the Company had done a large trade, and their plans for next year were for a greater trade. He moved that the scheme be approved. Dr. Iliffe, seconded, and stated that the new share capital would be called up at lengthened periods. After some discussion the scheme was put to the meeting and unanimously approved The Chairman then stated that it was a matter of satisfaction that £450 000 of proxies had been received in favour of the scheme, and over £100,000 were ordinary shares. The Chairman and Dr. Iliffe were thanked by the meeting, Mr. Stevens remarking that they had the courage to stick to the firm when the other directors were afraid to meet the shareholders. In accordance with the resolution, the Beeston Motor Company (Limited) has now been registered, with a capital of £110,000 in £1 shares.

G. R. Blot and Co. (Limited).

UNDER the above title a Company has been registered with a capital of £75,000, in shares of £1 each, for the purpose of manufacturing electrical and other apparatus and plant, and especially accumulators of the kind manufactured by Mr. G. R. Blot. The invention is patented practically all over the world, and the English Company acquires the patents of Great Britain, Canada, and several of the colonies, together with the right of taking out patents in all countries in which patents or protections do not already exist. We understand that the whole of the capital has been privately subscribed, and that the Company will at once get to work to place their accumulators upon the market in a commercial form. The directors are Mr. Thomas Parker, J.P., M.I.C.E., &c., of Thomas Parker (Limited), Wolverhampton; Mr. F. Hall Kirby, M.I.C.E.; Mr. Ernest Honey, of the Elswick Cycle Company (Limited); and Mr. G. R. Blot, the inventor. The offices of the Company are at 33, St. Swithin's Lane, London, E.C.

New and Mayne (Limited).

FOLLOWING the appointment of a receiver and manager upon the application of Mr. Rucker, a debenture-holder, made on September 15th last, in the above matter, two meetings have been held of the creditors of the Company at the Westminster Palace Hotel, the first being adjourned until the 10th inst. to enable a report to be drawn up for the creditors by a Committee appointed at the first meeting. The following gentlemen constituted the Committee :—Messrs. Reuben Hunt (R. Hunt and Co.), J. Strong (Henderson and Spalding), J. Hoyle (Dicks' Asbestos Company), and W. L. Gray (Dunlop Company). At the adjourned meeting, Mr. A. L. Basden, the receiver appointed by the Court, read the report drawn up by the creditors' Committee, which, after giving particulars of their investigations into the Company's affairs, the method of keeping the books, the proper issue of debentures, &c., pointed out that Mr. Rucker had from time to time advanced very large sums of money to the Company for the purpose of carrying on the business, amounting in the aggregate to close on £80,000, against which Mr. Rucker held some £53,000 of first debentures. After several interviews and a good deal of negotiation, the Committee had arranged with Mr. Rucker, subject to the creditors consenting to the reconstruction of the Company upon the lines indicated in the scheme set forth in the original circular, to accept in the reconstructed Company £25,000 in first mortgage debentures, and for the balance of his debentures he was willing to accept second mortgage debentures *pro rata* with the rest of the unsecured creditors, who would also receive a similar security in the reconstructed Company for the full amount of their debts. The Committee in their report then unanimously and strongly recommended the full acceptance of the amended reconstruction scheme, and a resolution to that effect being put to the meeting was carried with only one dissentient, viz., a representative of Messrs. J. K. and R. Lord, who recently filed a petition in the Companies' Winding-Up Court for the compulsory winding-up of New and Mayne (Limited). The resolution was then declared carried, and the necessary creditors' signatures obtained to enable the receiver and manager to obtain the consent of the High Court to the reconstruction scheme agreed upon by the creditors.

The Committee appear to have done their work admirably, and the unsecured creditors have to thank Mr. Rucker for the extremely generous way in which he has dealt with his claims upon the entire assets of the Company. There is no question in our mind that the creditors have a very substantial chance of obtaining their money back ultimately, as there is little doubt that New and Mayne (Limited) have valuable assets, which, if properly worked, should, under the coming condition of affairs in the automotor industry, result in the building up of a very valuable business.

Leather-Shod Wheel Company.

A LARGE company of shareholders met at the works of the Leather-Shod Wheel Company (Limited), at Bow Road, E., last month, for the purpose of witnessing a demonstration of the process by which the Company manufactures leather tyres and applies them to wheels of all kinds. It is claimed for the leather tyre invented by Messrs. Pierrou and Klein in 1895—the patent rights of which for the United Kingdom the Leather-Shod Wheel Company (Limited) was formed to take over—that it is at once elastic, durable, quiet, cheap, and light running. In the year mentioned works were started in Vienna, and the Austrian Government very soon began to use the wheels in several of their departments.

Upon the formation of the English Company, among the first orders given was one for wheels for the trolleys in the House of Commons. Then the Secretary of State for War gave an order for wheels for military carriages, and another came from the Director of Clothing of the Royal Army Clothing Department. Instructions were also received before many weeks had passed to prepare trial sets of wheels for the General Post Office, the London Road-Car Company, the Maxim-Nordenfelt Guns and Ammunition Company, Messrs. Merryweather and Sons for fire-engines, and a set of wheels for use on one of the London Tramways. In all these cases it is said the trials made have proved satisfactory, and orders have been sent in for wheels, not only for ordinary carriages, cars, and vans, but also for trucks, trolleys, machine pulleys, roller skates, friction wheels for transmitting power, rollers for bridges and gates, seed crushers, &c.

It is stated that, in addition to the quiet running, it is so elastic that a wheel dropped on a wooden floor will rebound about one-fifth of the distance. In Vienna it is found that the leather tyres last nearly as long as iron tyres, and three to four times as long as tyres made of rubber. As to cost, a whole wheel fitted with the leather tyre can be supplied at the same price as a rubber tyre alone. It is further claimed that considerable economy is effected in repairs of vehicles using these tyres, it being found that vehicles using elastic tyres last much longer than others. Moreover, it is contended that the tyre will stand such heavy weights that a tread as narrow as two inches can, if desired, be used for vehicles carrying loads of five tons upon each wheel, and in support of this statement are instanced the leather-shod wheels used for artillery purposes by the well-known firm of Fried. Krupp, gun-makers, of Essen. Any existing wheel can have the tyre attached rapidly and cheaply.

The process of manufacture, as explained to the shareholders by Mr. H. S. Fearon, the Company's engineer, is as follows:—Strips of leather are first passed into a machine and stamped into dies, which, having also been glued in the operation, are pressed into a cylinder and then delivered into racks in long segments. A whole tyre is made up and placed into a frame, which holds it tightly, and it is then several inches in diameter larger than the wheel for which it is intended. Upon being placed around the wheel, to the rim of which a vertical channel has already been attached, it undergoes a very great circumferential hydraulic pressure, and is contracted into the channel, the edges of which are subsequently turned in upon the leather, thus holding the whole firmly in position. A large factory is in course of construction, and in a few weeks it is expected that the Company will be manufacturing wheels in considerable quantities. The tyring machines are capable of turning out 300 wheels per day, three feet in diameter, with only 60 workmen.

British Motor Syndicate.

THE report of the directors of the British Motor Syndicate (Limited), with balance-sheet and profit and loss account from the date of incorporation to 30th September, 1897, to be submitted to the general meeting to be held at Coventry on the 18th inst., states that the gross profits, before charging directors' fees, amount to £446,285. Dividends and bonuses have been paid absorbing £217,173, and the Board have thought it wise at this time to utilise a considerable portion of the balance of profits in writing liberal sums off the cost of patents, freehold property, furniture, &c., as shown in the accounts. The cost of patents amounts to no less than £413,682, whereas the capital issued to the same date is £250.000, so that nearly half the cost of the patents has been paid out of the profits, and not out of the capital. Last year the Board's efforts were principally directed towards obtaining the necessary funds for purchasing controlling patents—the motor car as now used being quite a modern invention. This year attention has been given to the manufacture of motor-cars in this country, and the industry has now been thoroughly established. The progress made is seen by the fact that, whereas last November no British-made motor car was in existence, to-day upwards of 200 motors and motor-cars have already been turned out by the Company's various licensees at Coventry, and motor-cars are being delivered weekly. So far all attempts to excel the patents and inventions belonging to this Syndicate have signally failed, and all tests, public and private, indicate that their Systems are the only practical ones of any value, and will be found the controlling powers in the industry for years to come. All the international competitions and races have again this year been won by motors in accordance with the patents held by the Syndicate. The directors further report the continued success of their litigation. All points hitherto contested in the Law Courts have been won by the Syndicate. It has been deemed prudent to restrict the issue of new licences for the present, in view of the rapid developments now taking place. With reference to the Syndicate's electrical patents, no better evidence could be given than the electrical cabs now running in the streets of London under the Company's licence. The able management of the London Electrical Cab Company has silenced misrepresentations with reference to electrical motors. The oil-motors have a long list of records for the year in speed. In certain Government departments they are being submitted to severe tests, and the reports to date are in every way favourable. It is a matter for congratulation that in less than two years this Syndicate has obtained the premier position in this country. More progress is shown here than even in America or Germany. Only in France has this been exceeded, where, after the most thorough testing, the motor is being adopted by the railway companies, the post office, the army, and is rapidly coming into general use for large establishments, as effecting great economy in time and money. The state of the share market and the Jubilee year have deferred the launching of any new enterprise this year. Time is, however, in the Company's favour, as the motor is each day gaining ground, and the position is strengthening. The directors are now preparing plans for extensive developments next year.

With the report is issued a circular announcing that an extraordinary meeting of the Syndicate is to be held at the close of the ordinary meeting for the purpose of passing certain resolutions to alter the articles of association (which alterations are rendered necessary in order that the Syndicate may apply for a Stock Exchange quotation, and by reason of the extension of the Syndicate's business which is now transpiring), and to divide the existing capital of the Syndicate into two classes of shares—preference and ordinary. The meetings will be held at Coventry in order that shareholders may inspect the motor-mills there situated, which are proposed to be taken over.

I have examined the books of the British Motor Syndicate (Limited) from November 21st, 1895, the date of incorporation, to September 30th, 1897. Payments in relation to the Motor-Car Club, amounting to £4,378 8*s*. 2*d*., have been charged in the accounts as an expense. A sum of £1,664 13*s*. 4*d*. has been paid in respect of income-tax, but no reserve has been made for the balance payable, as yet unascertained. Subject to the foregoing remarks I am of opinion that the balance-sheet, which is in accordance with the books of the Syndicate, correctly exhibits the position of the Syndicate's affairs.

ERNEST BOOTHROYD, Chartered Accountant,
London, *November 1st*, 1897. Auditor.

Roller-Bearings Company.

THE ordinary general meeting of shareholders of the Roller-Bearings Company (Limited), was held on 28th October. Major-General Hutchinson, C.B., in the chair, during his speech said:—

The accounts of the Company relate, as will be observed from the balance sheet and profit and loss account, to a period of 15 months, from 2nd July, 1896, to 30th September, 1897, and, bearing in mind that the Company started to build up an absolutely new business, and had not the advantage of taking over a working concern, it will, we trust, be allowed that the results obtained during that period are not unsatisfactory. With reference to that paragraph in the report dealing with the number of bearings supplied, it may be interesting to state the various uses to which the bearings manufactured by this Company are being put.

For railway work considerable progress has been made during the last 12 months with the railway companies, both in this country and on the Continent. The London, Brighton, and South Coast Company, after experimenting themselves with these bearings for upwards of two years with satisfactory results, have now decided to adopt them for main line passenger traffic, and they, it is hoped, will shortly be fitted to their bogie stock. The South Eastern Railway have also determined to give them an extensive trial. The North Eastern Railway have been supplied with these bearings, and the Lynton and Barnstaple Railway, now approaching completion, have fitted the whole of their rolling stock with these bearings. With regard to electrical railways, the City and South London (King William Street to Stockwell) have fitted trains with them, and the directors are glad to announce that they have secured the contract for the whole of the rolling stock of the Waterloo and City Railway, and the whole of the carriages upon the Liverpool Overhead Railway are being gradually fitted with their bearings. The Mono-Rail Lightning Express Train at the Brussels Exhibition was fitted throughout with these bearings, and the directors have reason to believe that the results were satisfactory. The Company was awarded a silver medal diploma at the Exhibition for their exhibits. With respect to tramway works, the bearings have been supplied to gas, traction, and electrically worked cars for Blackpool, for cable cars at Edinburgh, and for horse tramways at Burnley, Worcester, Deptford, and Northampton. For motor-car work the bearings have already been supplied to Scarborough and Queensland; and bearings for shafting, furnace-cars, trollies, cranes, and ventilating fans for machinery have also been supplied by this Company, and negotiations are now in progress for fitting up electrical cabs, omnibuses, and other vehicles. Space has been taken at the Crystal Palace, where two loaded wagons are on view, one fitted with ordinary axle-boxes and the other with roller bearings. In conclusion, the demand for these roller bearings is steadily increasing, and the results obtained from their practical application in every-day use justify the directors in believing that the experimental stage of roller bearings is now passed, and that as their many advantages become more widely known and appreciated their success is assured, and their general adoption is only a question of gradual, if not of rapid, development. I now beg to move the adoption of the report and accounts.

Mr. W. SHELFORD seconded the motion, which was agreed to unanimously.

The Daimler Motor Company.

WORK ACCOMPLISHED—OUTLOOK FOR THE INDUSTRY AND DIVIDEND PROSPECTS.

THE second ordinary general meeting of the Daimler Motor Company (Limited) was held last month, under the presidency of Mr. H. J. J. Sturmey (the Chairman of the Company).

The Secretary (Mr. E. M. C. Instone) read the notice convening the meeting.

The CHAIRMAN said when he had the pleasure of meeting the shareholders at Coventry the Company was on the point of commencing actual deliveries of motors. That was in May, and although this balance-sheet took them very little into the actual period of production, he was inclined to congratulate the shareholders upon what he considered was a very successful result for their first year's working, in view of the fact of the long time necessary to organise the works. Remembering that they had undertaken the manufacture of an entirely new article, and that practically no one in this country was acquainted with it, he thought the time had not been wasted in any way upon it, and that the progress made had really been rapid. As would be seen from the balance-sheet (which was published in the October number of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL), the whole of their capital was subscribed. In regard to the item, plant and machinery, £17,752, if any of the shareholders were engineers, the directors most cordially invited them to make the most careful inspection of the works; whilst if they were not engineers, the Board would welcome the visit of any trained practical engineer in whom they might have faith and like to send. He thought that an inspection would show that for "up-to-dateness," completeness, and suitability for the work in hand they had the finest installation of plant and machinery in the trade, either in this country or abroad. For many months the work was that of preparation, and he need not tell the veriest novice at mechanical work that they could not make a complete article until they had every part—motor-gear, wheels, tyres, chains, and everything else. At the same time the work of producing those parts in quantity had been going on, so that although they had very few carriages actually finished, they had the parts ready for a very large number. When they had every part finished and ready to the hand of the builders it took something like a fortnight to erect the motor, and then various times, from a fortnight to as much as five weeks, for the motor to go through the testing shops for its many little adjustments and putting through tests in such a way that the Company could be satisfied that the motor was of the highest efficiency, and be need scarcely say that no motor was allowed to leave the shops until the Company's experts were thoroughly satisfied on that point. Then when the motor was finished there was quite as much work in the frame, gearing, &c., as in the motor itself. It took about three weeks to put the motor into its frame, and then there was the carriage builder's work, which was necessarily slow, paints and varnishes having to be used. The highest class of carriage took 16 coats of varnish, every one of which had to dry and then be rubbed perfectly smooth before the next coat was applied.

The Company had now 24 carriages going through the shops; they were finishing them now at the rate of four a week, and hoped before many weeks had passed to increase the number to six. With regard to the item leasehold land and buildings, £9,686, plus £3,894 spent on additions, he should explain that the first amount was entirely a profit transaction. The directors were fortunate in securing at Coventry a fine property of 13 acres of leasehold land with a double factory upon it. It had been built as a cotton factory, but had been burnt out, and was rebuilt by the insurance company: but the cotton company being wound up, it had not been occupied since. It came into the market at an absurd price—less than what the factory alone cost to build—and the directors lost no time in securing it, especially as at that time the British Motor Syndicate was floating the Great Horseless Carriage Company and searching for works in which to install it. They agreed to pay a fair price to the Daimler Company for one of the factories, that price being a sum which gave them a cash profit on the transaction as well as leaving them with the second factory and the surrounding land. The valuation of the land and buildings had been taken at the insurance value. The only portion of the report which at first sight might appear not at all satisfactory to shareholders, was the fact that although they had made a substantial profit they did not recommend the payment of a dividend. But it must be remembered that the profit be had shown was not a cash profit. The £9,686 was entirely in land and buildings, and not a trading profit in the ordinary sense of the term, so that it could not be distributed. Then, although upon the balance-sheet they had £10,000 on deposit, the directors had since had to pay for additional plant, and erect new workshops for building purposes, which had taken a considerable amount. It would have considerably hampered the future operations of the Company to have paid a dividend; but the directors were hoping that next year they would be able to do so, and that it would be the first of a very long series of highly-satisfactory dividends. It was important for this object that the public should purchase motor-cars in the same way in which they were purchasing in France, and he was glad to say that all signs pointed at the present time to an excellent business in the future for the Company. The chief enemy of the motor industry was a certain section of the press. At first they had nothing too good or too hopeful to say of them. They knew nothing about it, but from their writings gave the public the idea that the motor-car was a sort of thing that could be purchased for a small amount, cost nothing to keep, and that they had only to press a button and the motor would do all the rest. Since then many French and German carriages, many of them worn out before they got to this country, had appeared on our streets, and had not been altogether a success, with the result that a section of the press had turned right round and represented the motor car as a crude thing which ran for five miles and then stopped and was at any time liable to explosion. However, a great many people were having the cars, and he was pleased to say that everyone who had been supplied had been entirely satisfied with the result. With regard to their cars he could say positively that there was absolutely no smell which reached the occupants, and no vibration which would be noticed unless it were specially looked for, while with the exercise of ordinary care, such as had to be used in regard to gas, an explosion was practically impossible. There was absolutely no danger of the car running away; for they had no less than eight means of stopping it, and they could not very well all fail. He, personally, had a car delivered on September 9th, and up to the present he had driven it 1,029 miles. He had driven it from John o'Groats house and came right through the centre of Scotland, and not a single hill, up or down, had given him any trouble whatever. In future the directors' fees would be some £200 less, because they had received a letter that morning from Mr. Harry J. Lawson, stating that he found his time fully taken up with the work of the British Motor Syndicate, and felt obliged to resign his seat on this board, but he added that he should be happy always to afford the Company any help in his power. The Chairman then concluded by formally moving the adoption of the report and accounts.

MR. JAMES A. BRADSHAW seconded the motion, and said he had put his car to an exceedingly severe test, having taken seven passengers, including luggage and a reserve of oil, from Coventry to Liverpool at an average speed of 12 miles an hour, up hill and down dale. He thought that spoke volumes for the possibilities of the Daimler motor. The car was, as far as it was possible to judge at the present moment, almost perfect.

After a short discussion, the motion was unanimously carried.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

	Capital.
Beeston Motor Co., Ld.	£110,000
Blenheim Cycle Co., Ld.	100
Craven Cycle Co., Ld.	2,000
Cyclists' Chalet Co., Ld. (Coxston, Somerset)	30,000
Davidson's Air-Car Construction Syndicate, Ld.	20,000
Dunlop Motor Co., Ld. (14, Regent Street, W.)	25,000
Edward Foster & Sons, Ld. (Halifax and Bradford)	50,000
Edwin Clark & Co., Ld. (Banscombe, Rodborough, Gloucestershire)	3,500
G. R. Blot & Co., Ld. (33 St. Swithin's Lane, E.C.)	75,000
Kodak Cycle Co., Ld.	100
Licensed Tyre Synndicate, Ld.	10,000
Perambulator and Manufacturing Co., Ld.	10,000
Power and Traction, Ld.	10,000
Scottish Motor-Omnibus and Car Co., Ld. (66, Cadzow Street, Hamilton, N.B.)	5,000
Self-Generating Electric Vehicle Light Syndicate, Ld. (3 and 4, Crooked Lane, E.C.)	5,000
Shakespeare, Kirkland, & Frost, Ld. (274, Stratford Road, Birmingham)	15,000
Starleys, Ld. (Aitken Chambers, Cannon Street, Birmingham)	1,000
Thames Rubber Co., Ld. (14, Coventry Street, W.)	35,000

AN AUTOMOBILE HOUSE.

M. RENODIER, of Paris, sends us an account and a drawing of a house on wheels, which owing to the pressure on our space we are unable to reproduce, which has been constructed by M. Jentaud, the well-known French carriage-builder, and purchased by the former gentleman. It was originally intended to have been entered for Les Poids Lourds Competition, but could not be completed in time. The carriage, which in some respects resembles a large railway omnibus, is divided into two bedrooms—each containing two beds, a dressing room, bath room and lavatory, a kitchen, and sundry cupboards. The various apartments are entered from a corridor on the port or left-hand side of the carriage. The bedroom can be transformed at will into a dining or day room. There are two entrances, one on the side and the other at the rear end opening into the kitchen. All the rooms are tastefully furnished and well lighted by windows with lifting panes, as in railway carriages. The beds are 1·80 metre by 0·70 metre. The carriage is 7·70 metres long, 2·50 metres wide, and 2·40 metres high inside. The two bedrooms are each 2·0 metres by 1·80 metre; and the kitchen, 1·50 metre by 2·40 metres. The water supply for the kitchen, &c., consists of a tank which holds 200 litres. On the imperial are seats for 12 persons, and space for their provisions and baggage for a run of 400 to 500 kilometres. The carriage is supported by two wheels, and the fore end rests upon the tail of the tractor, which is by De Dion et Bouton, and is rated at 30 H.P., and which can carry water and fuel sufficient for a run of 500 kilometres. This tractor can haul a load of eight tons at a speed of 16 kilometres, and can easily take 10 per cent. gradients. The cost of fuel coke runs out at about 15 centimes per kilometre.

John o'Groat's to Land's End on a Motor Vehicle.—We congratulate Mr. Henry Sturmey, of the *Autocar*, on the successful completion of what we think is the longest continuous tour yet made in the British Isles in an automotor vehicle. He started from John o'Groat's House on the 2nd ult., and after travelling by easy stages, varying from 36 to 86 miles per day, arrived at Land's End at 4.35 p.m. on the 13th ult., having accomplished the journey of 929 miles at an average speed of just under 10 miles per hour all through, notwithstanding the fact that such elevations were crossed as the Ord of Caithness, the Grampian Mountains, the Pass of Killiekrankie, Kirkstone Pass into Ambleside, and the extremely hilly country between Exeter and Bodmin. Throughout the journey no breakdowns occurred, and all roads were traversed without trouble of any kind. Mr. Sturmey was accompanied by one servant, and carried between 200 and 300 lbs. of baggage, including a sufficiency of oil for the journey. The car used was of English manufacture, having been built by the Daimler Motor Company, and was fitted with a 4 H.P. motor propelled by benzoline. Part of the object of the tour was to prove the capabilities of the new mode of conveyance to surmount all hills which a capable bicyclist can master, and to travel successfully and without failure upon any high road in the kingdom, and in this Mr. Sturmey claims to have succeeded. Mr. Sturmey has since returned to Coventry, viâ London, on his automotor vehicle, which is none the worse for its long journey of over 1,500 miles.

THE HEILMANN ELECTRIC LOCOMOTIVE.

THE following are some particulars of the automotor which is being tried with great success on the Western Railway of France. The net weight is about 124 tons, the locomotive proper weighing 75 and the tender 49 tons; the latter can carry 19·6 tons, or 4,386 gallons of water. In appearance the locomotive is massive, but without being clumsy, it gives one the idea of concentrated energy. The design is well worked out. In working order the total weight of the engine, tender, coal water, &c., is 200 tons. There are eight pairs of wheels, each pair being driven by a 100 H.P. motor. These motors receive current from two dynamos of 1,000 ampères at 450 volts, but this output can be easily increased. These electric generators are mounted one at each end of verti.al engines, which are divided in two groups, each with three cylinders working on the compound system. These engines have been construoted by Willans and Robinson, and with them there has been overcome one of the difficulties experienced with the experimental engine, whereby excessive vibration was set up; the arrangement of the six cylinders gives effective balancing. The motor gives off 1,400 H.P., and at this power it can haul a train of not less than 588 tons weight at a speed of 37 miles per hour, or at a speed of 68 miles per hour it can haul a train of 245 tons weight. The heating surface of the boiler is slightly under 2,000 square feet, while the steam pressure is 200 lbs. The locomotive is 93 feet long over all, 9 feet wide; the chimney is 13 feet 9 inches above the rail level. Whether the comparatively light permanent way adopted in France will stand such heavy traffic is, however, doubtful; our own opinion is, that before the undoubted advantages of the Heilmann locomotive can be enjoyed rails of much heavier section, closer spaced sleepers, &c., must be employed. The first public trial trip took place on the 12th and was most successful. It may be mentioned that the famous McIntosh engine for the Caledonian Company, known as the Dunalistair, is 53 feet 4 inches long, including the tender, and weighs 86 tons. The corridor train taken by her weighs 354 tons, so that the Dunalistair's performance, especially over Beattock, is almost as good as the Heilmann.

AUTOMOBILISM AND THE FIRE BRIGADE OF THE LARGEST CITY OF THE WORLD.

ACCORDING to the report of the Fire Brigade Committee of the London County Council for the year ending March 31st last, issued a few days ago, the staff of the Brigade numbers 963. Firemen employed on watch by day at the stations throughout London number 140, and at the engine and escape stations by night 375, making a total of 515 in every 24 hours. The authorised strength of the Brigade includes 963 officers and men, comprising coachmen, pilots, and men under instruction; 58 land fire engine stations, 3 sub-stations, 16 permanent street stations, with fire-extinguishing and life-saving appliances, 204 fire-escape stations, 60 hose-cart stations, 11 hose and ladder truck stations, 5 river stations, 8 steam tugs, 13 barges, 9 carrying engines (4 being used as store barges), 9 steam fire engines on barges, 58 land steam fire engines, 66 6-inch manual fire engines called "curricles," 35 miles of hose, 115 hose carts and hose reels, 14 hose and ladder trucks, 7 horse tenders and fire-escapes combined, 12 vans for carrying hose, coal, fire-escapes, and stores, 4 wagons for street stations, 7 vehicles for use of officers when inspecting stations, &c., 226 fire escapes (inclusive of 11 small fire-escapes kept at police stations), 5 long fire-ladders, and 9 vans to carry the same, and 139 horses. The actual disbursements during 1896-7 on maintenance, including pensions, were £164,728, and on capital £75,031 2*s.* 7*d.*

Speaking generally, it must be said that most of this enormous plant is antiquated and obsolete in design, and generally inefficient: there is not a single steam motor which works at anything more than 150 lbs.—a comparatively low pressure. There is not a single electric pump. Flexible metal section hoses are things utterly unknown to the Fire Brigade, as are water towers and other improved means for dealing with fires. Lastly, *there is not a single automotor fire engine in the first city of the world.* Can it be wondered at that London fires are so frightfully destructive and so costly? Little or no improvement has been made in the plant of the Fire Brigade since the days of the old Metropolitan Board of Works.

LECTURES ON PATENT LAW.

A VERY important course of six lectures is now being delivered by J. Fletcher Moulton, Esq., Q.C., on "Patent Law," under the auspices of the Council of Legal Education, in the Middle Temple Hall. The first lecture was delivered on Tuesday, November 2nd. at 7.45 p.m., and the lectures will be continued at the same hour on subsequent Tuesdays. The following is a syllabus of the lectures:—

Lecture I.—Nature of Grant by Letters Patent.—Their Legal Status prior to Act of Monopolies.—Effect of that Act.—Practice and Procedure in the Sixteenth and Seventeenth Centuries.—Modern Developments.—Legal Status of Letters Patent under Existing Law.

Lecture II.—The Invention.—Difficulty of Definition of the Word "Invention."—Essential Characteristics of a Patentable Invention.—Negative Canons Derivable from Judicial Decisions.—Delimitation of the Invention in the Specification.—Origin and Function of Claims.—Their Interpretation.—Colourable Imitation.

Lecture III.—Conditions of Validity.—(1) Novelty:—Prior User.—Secret User.—Experimental User.—Prior Publication.—Its Sufficiency.—Conflicting Decisions.—Distinction between Public Knowledge and Common Knowledge.—Publication by the Inventor Himself.

Lecture IV.—Conditions of Validity (*continued*).—(2) Sufficiency of Specification:—Double Duty of the Patentee.—Difficulties arising therefrom.—Examples.—(3) Utility:—Origin and Nature of the Condition.—Meaning of the Term in Patent Law.—Commercial Utility.—(4) Conformity:—Origin and Nature of the Condition.—Fair Development.

Lecture V.—Procedure.—Mode of Obtaining the Grant.—Amendment of Grant.—Revocation of Grant.—Rights and Remedies of Patentee.—Rights and Remedies of Public.—Action for Threats.—Compulsory Licences.

Lecture VI.—Defects of English Patent Law.—Foreign Systems.—Relative Advantages.—Possible Improvements.—International Rights.

The lectures will be open to all members of the Inns of Court free, and to gentlemen non-members on payment of a fee of one guinea for the course. Tickets to be obtained at the office of the Council, Lincoln's Inn Hall, W.C.

Automotor Vehicles in Berlin.—A society has just been started in Berlin to promote the introduction of motor-cars on the Continent. In discussing this enterprise, the *Elektrotechnische Zeitschrift* brings forward certain statistics to show that the electric car, with accumulators, is not so very far behind the petroleum motor-car in weight and speed, and that for certain purposes, such as for cabs and parcel vans, the electric car has the advantage. A comparison is made between a Daimler benzine car and an electric car made by Kühlstein. Both these cars are capable of carrying five persons. If five persons are taken as weighing 400 kilogrammes, the comparison between the two cars is shown in the following table, using the figures given by the manufacturers:—

	Daimler.	Kühlstein.
Weight, fully loaded.. ..	1,550 kg.	2,000 kg.
Average speed per hour ..	12 miles.	8·4 miles.
Maximum speed per hour ..	15·6 miles.	12·8 miles.

The electric car contains 30 Correns cells, with a capacity of 250 ampère-hours. According to experiments by Correns, the Lundell motor on this car required 35 ampères on good stone pavement, 42 ampères on asphalt, and 60 ampères on the ordinary roads. One charge is sufficient to run 42 miles. The battery weighs 750 kilogrammes, and gives, with an average discharge current of 46 ampères, 14 kilowatt-hours or 1 kilowatt hour per 53 kilogrammes of battery. The London electric cab, carrying three persons, weighs 1,500 kilogrammes, and has an average speed of 9·6 miles per hour. Its horse-power, compared with Kühlstein's car, is as 24 to 28, and the weight of the batteries as 70 to 75. Since the London cabs run 41 miles with one charge, the product of weight × run is 72 mile-tons, while with the Kühlstein car it is 84 mile-tons. Our German contemporary concludes, from these figures, that Kühlstein's car is 9 per cent. better than the London cab in power developed per unit weight of battery.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale: BRETT AND Co., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham: J. McCANN, 37, Union Street.
Manchester: JOHN HEYWOOD, Deansgate.
Newcastle-on-Tyne: C. C. ROSS, 35, Side.
Paris: HOMÈRE MOREAU, 97, Rue Nollet.
Victoria (Australia): PHILLIPS, ORMONDE, AND Co., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

NOVEMBER 16TH, 1897.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

1897.

Nov. 19-27	..	Motor-Vehicles at the Stanley Show, Agricultural Hall, London.
Nov. 26	..	Opening Session of Self-Propelled Traffic Association (Liverpool Centre). Address, with lantern illustrations: "Self-Propelled Vehicles, 1896-7," by Worby Beaumont, M.I.C.E., &c.
		Motor-Car Club Annual Meet. Hôtel Métropole, London, 11 a.m. Drive to Sheen House Club, Richmond Park. Returning at 4 p.m.
Dec. 13	..	Yorkshire College Engineering Society—"The Daimler Motor and its Application to Auto-Cars" (illustrated), by J. Sidney Critchley (Daimler Motor Co.).

1898.

Jan. ..	..	Exhibition of Locomotion and Engineering, Rifle Barracks, Belle Vue, Bradford.
Jan. 11	..	Liverpool Cycle and Motor-Car Exhibition, Liverpool.
Jan. 20-29	..	Midland Cycle and Motor-Car Exhibition, Bingley Hall, Birmingham.
Feb. 3-12	..	Sheffield Cycle, Motor-Car, and Accessories Exhibition, Drill Hall, Sheffield.
Feb. 14	..	Yorkshire College Engineering Society—"The Steam Turbine Engine and its Applications," by John D. Bailie (C. A. Parsons and Co., Newcastle).
May 2, 9, 16, 23		Society of Arts Cantor Lectures—"Electric Traction," by Prof. Carus Wilson.
May 24	..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
June ..	..	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
July 5..	..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
1899 ..	..	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900 ..	..	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

G. A. (Sheffield).—Copy sent as desired. We thank you for your expressions of appreciation.

J. G. (Carnoustie).—We have sent your letter on as desired. For future guidance, however, you might note the postage is 2½*d.* The address is 13, Boulevard Malesherbes, Paris.

H. EVANS (Worcester).—We thank you for returning the paper. The address of Mr. J. S. Bickford is Camborne.

J. P. HITCHIN (Rochdale).—A Company is in formation for working the English patents, and will shortly be carried through. A lorry upon this principle has already been constructed in England, and the Company hold the patent rights for Great Britain. The registered offices of the Company are 7, Poultry, London, E.C.

W. B. B. (Hayward's Heath).—The only bath chair motor attachment which we know is one supplied by the Britannia Motor-Carriage Company, of Woodstock Road, Shepherd's Bush. Mr. John Ward, of 246, Tottenham Court Road, has, we believe, one on view at his premises. The motor is electric. You might try New and Mayne, Woking.

A. A. C. (Bedford), R. C. F. (Gloucester), J. B. (Kenilworth), J. E. (Invicta).—We regret it is impossible to supply you with No. 1, Vol. I. The only form in which you can procure it, we are afraid, is in a bound volume at one guinea, which price is likely to increase. Practically all the rest of the numbers can be obtained at the ordinary price.

J. E. F. J. W. (Llandudno).—You did not send your change of address. Hence the reason of your not receiving the paper. We are now forwarding back numbers as desired.

J. W. (Southend-on-Sea).—The address of M. Peugeot is Mandeure, Doubs, France.

THE SELF-PROPELLED TRAFFIC ASSOCIATION'S COMPETITIONS.

ELSEWHERE in the present issue we publish the rules drawn up by the Self-Propelled Traffic Association for the conduct of the competition to be held next year in Liverpool. As will be seen, considerable care has been taken in framing them so as to not only secure the object that the Association has in view, but also to give designers the widest possible latitude. In order to ensure the former the judges will be selected from the Council of the Association, and no difficulty should be experienced in finding suitable men for this purpose. Inasmuch as the S.P.T.A. was largely, we had almost said entirely, formed to develop motor traffic in goods on commercial lines between large towns, the nature of the problem to be solved is not altogether the same as that which existed in *The Engineer* and Les Poids Lourds Competition. In these a more catholic idea was sought to be achieved. In the S.P.T.A. the problem is more definite. The loads to be carried, the work the vehicles will have to do, the routes to be traversed, are all known, and hence judges conversant with the Liverpool and Manchester trade will no doubt be able to make a more suitable choice—that is for their own local conditions. In the district named much produce is carted to and from the docks in large "floats." These are easily laden, the "lift" being not more than a foot or so. The cotton, Jaggary, hides, &c., are usually carted away on four-wheeled open-sided wagons, whose platform is about 3 feet 6 inches or 4 feet from the ground. We mention these things as being possibly serviceable hints to intending competitors. Indeed, we should strongly recommend the latter to study the local conditions on the spot, because it is certain, as can be gathered from the rules, that the competition will be a drastic one. The Liverpool merchants are quite prepared to place a large order with the maker of a vehicle that meets their views, but they won't spend sixpence on an experiment; and competitors will do well to remember that a motor-vehicle which might suit London traffic might not be acceptable in Liverpool. As will be seen, money prizes will be offered, but we do not think this an inducement. The problem, although, as we say, a definite one, is yet a difficult one. The desired motor-van is to have a net carrying capacity of 10 tons, a platform area of 110 square feet, and a mean speed of four miles per hour. It must also of necessity comply with the Locomotives on Highways Act, that is, its weight must not exceed (tare) three tons. If one runs out the salient features of a design (as we have) it will be seen that in order to get within the Act a very special design is called for. It was, we think, the difficulty of complying with the conditions laid down by *The Engineer* and the Act of Parliament that rendered the competition of our contemporary so nugatory. One cannot study the Locomotives on Highways Act without concluding that it appears to have been drawn with the evident intention of delaying the introduction of heavy automotor vehicles as long as possible. It is well known that both in the Lords and Commons there was an influential opposition to the measure, and this had to be so far placated as to render the Act partially inoperative by this limit of three tons, and also by insisting upon a low speed. We are not at all sure that the S.P.T.A. will not be well advised if it directs its energies towards obtaining an amendment to the Act in the next Parliament.

When we remember, too, that in and around Liverpool the gradients are often such that ample motive and braking power are absolutely essential, it will be realised that the problem is, as we say, a most difficult one. One of the conditions that we do not quite see the reason of, is that the mechanism shall be below the platform. Considering that the loading brows in the docks are not more than 2 feet 6 inches or 3 feet high, and that the platform must hardly be higher than this, we think this condition unnecessary. It will be noticed, too, that while the length of the vehicle is determined it is permissible to make it articulated, that is, it can consist of a long "float," the forepart of which rests on a motor-vehicle. We do not think this design will commend itself owing to the additional weight involved in the extra pair of wheels.

We have not the slightest doubt that both the conditions of the S.P.T.A. competition and the Act of Parliament can be amply fulfilled. What we do hesitate about is, whether there will be a sufficiency of competitors. One might produce a successful vehicle, but it might fail in some minor point, and even a prize or certificate of merit would not compensate the manufacturers for time and materials expended. There is, however, no doubt that the S.P.T.A. is making every effort to solve the problem of heavy automobilism, and we sincerely trust that it will be successful.

In conclusion, we would point out that the subject of automotor vehicles capable of carrying loads of 5-10 tons has now been before the engineering community for twelve months. Ample time has been afforded for the elaboration of designs, and we would ask English engineers—Is this problem of heavy automobilism to be solved on this side of the channel, or will it be left for the highly-trained and technically-educated French or German engineers to show us how it's done?

Owing to the pressure on our space this month we are obliged to hold over much important matter relating to the proceedings of the engineering societies dealing with automobilism.—Ed.

OUR IDEA ENTIRELY.

In the July number of the Automotor, on p. 415, we propounded, in an article entitled "The Automotor Industry, and How to Foster It," the idea of establishing an exchange. We wrote:—"We propose that in London and the large provincial cities, such as Liverpool, Glasgow, Manchester, Birmingham, &c., there should be formed Automotor Exchanges—that is, manufacturers and designers of automotors should form a parent Association, with branches in these towns. At each branch there would be a depôt, with examples of each type of motor. A would-be purchaser would thus be able to inspect the whole industry at a glance, and obtain the fullest technical information. Trials could be arranged, and purchases effected with the least trouble, and with the best possible guarantee that the purchaser had obtained what he required. A trial might well be made of this idea in London to start with. It is, of course, not intended to have anything in the nature of, or savouring of, an 'Exhibition.' Our idea is that of a purely business Exchange, where one could see samples of motors and obtain quotations exactly in the same way as one can go into the Corn or Wool Exchange and obtain samples and prices of these articles."

We, of course, are only too pleased that our contemporaries should adopt this idea, but, without wishing to claim any credit for it as a brilliant inspiration, we think that inasmuch as such Exchanges as we mentioned will undoubtedly be established, and as a matter of historical accuracy for the guidance of future writers on the history of automobilism, not to mention such minor considerations as journalistic etiquette, it should be clearly understood that the idea in question was first promulgated by this journal. We mention this because we see *La Locomotion Automobile* lays claim to the inception of the idea, and the *Autocar*, in its issue of October 16th, says with charming naïveté:—"Our contemporary, the *Locomotion Automobile*, has suggested that the difficulty could be overcome by establishing a permanent exhibition of autocars, and of industries attaching thereto. Such a show has become so indispensable that one wonders why it was not thought of before." Really! It has been thought of before.

STABLE FIRES.

One of the many evils attending the housing and accommodation of horses is that the risk of fire is always present, and cannot well be eliminated. As the number of horses is increased, so does the risk of fire become greater, and the Fire Insurance Companies regard stables with well-founded dislike. In London where space is so costly, it has become the practice to house the horses in flats, and when it is considered what a large amount of dry hay and straw is required to feed even a moderate stable of 50 horses, and how this dry and easily-ignited material is scattered about, it will be seen that the risk is a serious one. That it is so is from time to time demonstrated by the fires which take place in connection with stables. Quite recently the well-known carriers, Messrs. Carter, Paterson, and Co., had their stables in the Goswell Road burnt out. Fortunately, owing to the prompt assistance of the Fire Brigade, nearly all the horses were saved, but the damage done to plant, goods, &c., was very great. The firm in question had a very complete and well-arranged block of stables, and it is difficult to account for the fire, unless it be attributed to carelessness or malice. Inasmuch, however, as some explanation had to be given, it occurred to certain scribes to attribute it to the motor-car. The chain of reasoning by which this conclusion is reached is not very strong, but it will serve the purpose of those newspapers which—sticklers for the old order—seek to discredit automobilism. It seems that Messrs. Carter, Paterson, and Co. use motor-vehicles for their business, and hence what more likely than that these new-fangled things caught fire or exploded? As David might say to Acres, "I suppose there ain't been so merciless a beast in the world as your loaded—motor." At any rate this is the idea that not a few writers on the Press—whether from knowledge, which we doubt, or silly prejudice, which we think—entertain. Thus the *Globe* in an inconsequential paragraph said :—

"The pros and cons of motor-car *versus* horse continue to oscillate with nicety, and a large con was registered yesterday when a conflagration broke out in Messrs. Carter, Paterson's depôt through, it is believed, an explosion of stored gas for the Company's motor-cars. It is true that your motor-car needs no oats; but, on the other hand, your horse never spontaneously combusts himself and his surroundings. If the horses which were rescued with difficulty from yesterday's fire could have given their opinions of motor-cars, we might have obtained something more interesting than printable."

On seeing this we immediately communicated with the firm in question, and these gentlemen informed us that there was absolutely no evidence to connect the fire with the motor-vehicles. It is easy to see that the writer of the above precious paragraph knows nothing whatever of motor-vehicles or he would not talk about "an explosion of stored gas." If he and others after his kind would store their brains with a few elementary facts of engineering science they would do their papers more credit and their profession also. The ignorance of a large section of the daily Press on this and similar subjects is truly pitiable. However, here is another lie exposed.

RACING ON ROADS AND HIGH SPEED ON ROADS.

THE National Cyclists' Union has at length, we are glad to say, prohibited road racing or pacing, and the reason is that such locomotion may be dangerous to the public. No sane person will, we think, dispute or deny this danger, and, for our part, we think that all persons who "scorch" on any kind of vehicle, and who thereby lessen the safety of the public to any degree whatever, ought to be severely punished; much more severely, in fact, than has been customary. While saying this it must be distinctly understood that driving a vehicle other than an automotor-vehicle at a high speed is not *per se* unlawful, it is only so when danger to the public is caused, or is likely to result. This view of the law was recently laid down by the Lord Sheriff Brown in the Aberdeen Court (*vide* AUTOMOTOR for October). The learned Judge said :—"If a bicycle was a carriage, and so declared by statute, the prosecutor had never yet succeeded in obtaining a conviction against a driver of a carriage for furious driving, except on proof that in point of fact danger to the public had emerged."

So far as cycles and horse-drawn vehicles are concerned, high speeds may be lawfully indulged in within this limitation. It is, however, because cyclists have shown such a disregard for the rights of pedestrians that they have now to take united action against those of their own body who would use the road for racing purposes. Racing is an unlawful act, as the highway is not, and never has been, recognised as a racing track. It is very necessary that all who use the road in any way, and especially those who administer the law as to vehicles and highways, should have clear ideas on the subject. At present convictions for furious driving are based not upon whether there was or was not danger to the public, but upon the evidence of some illiterate policeman and the personal predilection of some magistrate, who in too many cases is a distinctly prejudiced party. Police evidence is naturally and of necessity biassed. We must remember that the policeman is keenly and personally interested in obtaining a list of convictions with as little personal risk to himself as possible, because the more convictions he obtains the quicker his promotion. It is to his manifest interest to secure a conviction, and cyclists afford an easy and grateful prey.

British law is rarely logical, and the term "furious driving" well exemplifies this. It is not the actual velocity of a mass which does harm, but it is the amount of kinetic energy contained in it which determines the results. A swallow, weighing a few ounces, will fly at a speed of 30 miles per hour against the glass of a lighthouse, and the kinetic energy it develops, while harmless to the glass, is taken up by the bird with the result that it fractures its limbs. A cycle and its rider, weighing 180 lbs. and travelling at 12 miles per hour, will develop 765 foot lbs. of energy. This is, of course, more than sufficient to capsize any pedestrian, but if instead of a human body, it is a wall with which the cyclist collides, the chances are that he will be maimed for life and his machine will be past repair. It is a very common sight to see in London a van drawn by a pair of fresh horses being driven at a rate of eight or nine miles per hour, but it is very uncommon to see proceedings taken against the drivers. The weight of the van (empty) and horses will be certainly not less than $3\frac{1}{2}$ tons and at 8 miles the kinetic energy will be 16,660 foot lbs., yet a motor-van, weighing (empty) 26 cwt., would have to go at a speed of over 13 miles per hour to develop this amount of kinetic energy. Notwithstanding that the motor-van could be stopped in one-fourth to one-third of the distance that the horse-drawn van could be, and could be manœuvred so much more easily, the intelligent policeman and the sapient magistrate would undoubtedly convict the driver of the motor of "furious driving," utterly oblivious of the fact that it could not possibly do more damage than a van weighing nearly three times as much, but only going about two-thirds the speed. It is this failure to recognise the science and the law of the thing which makes many of these prosecutions for furious driving so unjust, not to say ridiculous. Defendants in these cases would do well to consider this view of the question. It, of course, may be urged that it is easier to get out of the way of a heavy brewer's dray than it is to get out of the way of a "scorching" cyclist. It is; but the mere fact that it *is* necessary to get out of the latter's way establishes "furious driving" on his part and the law provides for this.

G. H. L.

THE THAMES STEAMBOAT SERVICE.

As will be seen from a report that we publish elsewhere, there is every likelihood that the great problem of the congestion of the streets of London will be partially solved by the establishment of an efficient service of river automotors. That London in this particular matter should be so far behind other capital cities is to many people inexplicable, but if we remember that for many centuries the banks of the river, say, from Westminster to Blackwall, have been occupied by private owners, and that access to the river can even now only be obtained at certain points, and that by traversing dark and devious passages not always free from danger, the gradual diminution of the popularity of the river as a means of passenger transport is easily accounted for. Take, for instance, the approaches to Wapping Stairs or Cherry Gardens Pier. No one having valuables upon them would care to seek out these piers after dark. As will be seen, the first step is to acquire the piers, at present owned by the Thames Conservancy; and if the Council succeeds in this the next thing will be to sell them again to the "knacker." These piers are, for the most part, "dummy" lighters, with no proper accommodation or protection against the weather, they are all very old, rickety things, not worth repairing or reconstructing, and fit only for "scrap." Larger and more commodious pontoon piers, with glazed and warmed waiting-rooms, should be built; these should be moored at more convenient stations than are the present ones. The approaches to the piers should be wide and well lighted, and the connecting bridges should be covered in and glazed. As regards the vessels, considering that the Council will eventually acquire them, as they have the trams, there will be no excuse for not providing much better boats than those in use at present. These vessels are utterly obsolete in every way. Their design is wretched, and their accommodation as bad as can be; there is no efficient subdivision, and no adequate protection for buoyancy. In fact, there has been little or no substantial improvement in these river vessels ever since the "Princess Alice" disaster. The Council will, we trust, insist upon the Company that proposes to work the traffic complying with a pretty tight specification as regards hull, machinery, &c. A mean speed of not less than 15 knots should be insisted upon. The machinery should consist of oil-fired water-tube boilers supplying steam to horizontal three-stage compound engines driving dynamos which, by means of electro motors, would drive the twin screws; or perhaps a better arrangement would be to use Parsons's turbines; the object in each case being to get all the machinery below the main-deck, and to have absolutely no vibration. The modern but obsolete torpedo-catcher engine-room practice should be avoided. As regards the design on deck, this should be a radical departure from the existing open-deck arrangement. American river boat practice might be to a certain extent followed.

Lastly, but of equal importance, is the question of *personnel*. The boats must be properly manned; the public will not trust themselves to rough, uncouth, uncertificated watermen; at least, no one cares to do so. The Council should insist that all the mates and masters should at least have home trade certificates, while the engineers should be required to hold, at any rate, a second's ticket. We have thrown out these few suggestions as the result of our own experience with vessels in various parts of the world, and in the hope that they may serve to guide those concerned, and of others desirous, as we are, of seeing the Thames become the favourite route. We congratulate the Rivers Committee and the Council on their efforts so far, and we feel assured that the ratepayers will cheerfully lend their aid to further this scheme of municipal and nautical automobilism.

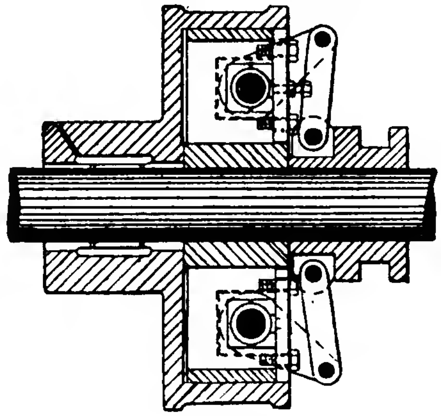
G. H. L.

Curious Collision between Motor Vehicles.—In the afternoon of October 13th a curious accident occurred in Charing Cross Road. A motor-van, belonging to a parcels delivery company, was crossing from Shaftesbury Avenue in the direction of the Palace Theatre, when two omnibuses drove across in front of the van, the drivers making disparaging remarks to the motor man. Behind the omnibuses was a second motor-van, belonging to a patent medicine company, and the driver of the first motor vehicle, turning, it is said, to answer the omnibus drivers, did not see the second motor, with which his own came into collision. The wheels of the two became locked and remained so for some time, the crowd laughing, and cabmen and omnibus drivers jeering. One of the motors could not start again for ten minutes, and when it did move (with the aid of boys pushing) the crowd cheered lustily. Beyond the damage to the paint the motors seemed to be none the worse for the accident. It is to be regretted that steps are not taken by the owners of motor vehicles to check the vulgar and offensive abuse of omnibus and cab drivers. The Police Regulations are quite clear as to the offence in question.

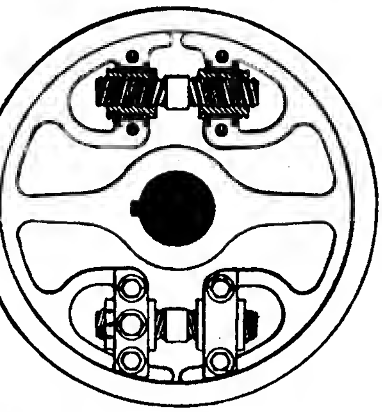
A New Motor-Car and Cycle Club.—Mr. Howard Fenney, a director of Messrs. Hearl and Tonks, is about to establish a club in Birmingham, where those interested in automobilism can meet. The building is a new one, and is rapidly approaching completion; the cost is said to be £12,000, which has been found entirely by Mr. Fenney. When finished, it is intended to let the building, furnished complete, to a limited liability club, at an annual rental to be fixed by an independent valuer. The accommodation will be of the very best, and will comprise in the basement a show-room, where cases containing samples of the goods manufactured by each member may be on view, as also stalls for the sale of all the chief cycle and trade newspapers. The ground floor will be formed into a kind of cycle exchange, where members may meet their customers and transact business, discuss the market quotations, and effect "deals" in cycle shares, &c. Further ahead will be reading, writing, smoking, and general reception rooms, as also a large dining-room, where meals can be obtained at any time of the day. Then, of course, there will be the necessary recreation and billiard rooms, all furnished in the most luxurious style. It is intended to conduct the club on the soundest lines, the membership being limited to principals only, and already a number of the most influential gentlemen connected with the trade have promised to take an active part in the management.

HALSTEAD AND HORSBURGH'S FRICTION CLUTCH.

For those automotor vehicles in which oil-motors are employed, a clutch which permits of rapid engagement and disengagement without shock is an essential fitting. As is well-known, oil-motors have to be run at practically a constant speed, and any variation in the speed is best effected by means of a good clutch which enables the various gears to be quietly thrown in and out of gear. The accompanying illustrations show the clutch invented and manufactured by Messrs. Halstead and Horsburgh. It consists of a split ring which, by means of two right and left-handed screws and toggle levers, can be expanded so as to grip the internal periphery of a shell pulley. As will be seen, provision is made for adjusting two of the nuts



with which the screws engage, so that the effects of wear may be readily compensated for. When correctly adjusted the toggle levers assume the position shown in the sectional view when the clutch is in gear, thus relieving the brasses or starting levers of any pressure, and rendering the clutch self-locking. A further advantage is that the clutch, being perfectly symmetrical, is naturally balanced, and can therefore be used at the highest speeds.



Messrs. Halstead and Horsburgh claim the following advantages for this clutch:—It transmits more power than any other friction clutch of equal diameter. There are no parts liable to get out of order or lock; and any required adjustment may be made whilst engine is running; all parts are interchangeable. It is also self-locking when in gear, and there is no end thrust on brasses or starting levers; it also works vertically or horizontally.

NOTES OF THE MONTH.

A CYCLE, motor-car, and accessories exhibition will be held at the Sheffield Drill Hall, from February 3rd to February 12th, 1898.

THE Kensington Vestry is going to try an automotor vehicle instead of horses, to see if there will be any saving to the ratepayers.

WITH due appreciation of the fitness of things, the members of the Hammersmith Vestry, on the occasion of the recent inauguration of their New Central Electric Light Station, drove to the scene of the function in electric cabs.

THE De Dion Tricycle which the Hon. C. S. Rolls recently acquired is, we understand, turning out a great success. It is particularly suitable for racing, Mr. Rolls having recently paced a cycling friend for 100 miles, which was accomplished in 5 hours 4½ minutes.

THERE will again be a gathering of motor-cars during the Stanley Show this month at the Agricultural Hall. They will be on view in the King Edward's Hall, the exhibiting firms being Humber and Co., Daimler Motor Company, and the Great Horseless Carriage Company.

THE Dunlop Company have decided to embark upon the manufacture of motor-vehicles, and have recently started a subsidiary company with a capital of £25,000 for this purpose. Mr. A. Herschmann is their chief draughtsman, and their works will be situated at Bournbrook, near Birmingham.

WE hear that it is proposed to establish a service of motor-vehicles from Lincoln to Brigg and back, a distance of 42 miles, and passing no less than 29 villages *en route*. We should think that the scheme has every promise of success in it. Mr. E. Danbney, of 9, Chaplin Street, Lincoln, is the Secretary *pro tem.*

WE regret to chronicle the death of Mr. W. Arnold, of the firm of Messrs. Arnold and Sons, engineers, of East Peckham, at the age of 78 years. The deceased gentleman had devoted much time and thought to automobilism, and was the inventor of the very successful type of motor-vehicle which bears his name.

The G.P.O. Authorities are using an electric motor van for the conveyance of mails, parcels, &c., between St. Martin's-le-Grand and Victoria. It makes five journeys per day. So far it has proved itself to be a distinct success in every way, and we hear that the G.P.O. contemplates the use of such vans in the larger provincial cities.

No less than 400 patents have been granted for acetylene gas; and 12 companies, having over half a million of capital, have been formed, and yet only one factory is producing calcium of carbide. Although there are 16 works elsewhere, several of them are on a small scale, and the production is due to the inflated price obtained for the carbide. The only British factory is at Foyers, N.B.

Animals' Friend, in speaking of the automotor, says:—"Patronise the motor-cab and car. It will abolish the tired and broken-down horse from the street and highway, the public thoroughfares will be more sanitary, and there will be no more equine suffering in the wet and cold of wintry nights when masters and mistresses are pleasuring." Our humane contemporary adds that "the horrors of the midnight cab rank have yet to be told."

THE Yorkshire Motor-Car Company, of Albert Buildings, Bradford, has arranged for an exhibition of motor-cars, motor-wagons, motor-cycles, accessories, &c., to be held during December or January, at the Rifle Barracks, Belle Vue, Bradford. Mr. J. E. Tuke, with his usual energy, is the moving spirit in this exhibition, which we wish every success. The Company over which this gentleman presides is thoroughly up-to-date, and prepared to supply all the best forms of motor-cars and tricycles at moderate prices, ranging from £75 upwards. At the latter figure the price list includes a vehicle capable of running 100 miles at the stupendous cost of 1*s.* for fuel!

ON the 25th of last month the Scottish Motor, Omnibus, and Car Company (Limited) started the running of motor-cars between Hamilton and Larkhall and Hamilton and Blantyre; a service for Hamilton, Bothwell, and Uddingston being also started on the 26th. The cars run every hour, at moderate rates. They are elegant and light, and are seated for six outside, with accommodation for one or two more beside the driver. From reports to hand they are being well patronised, numerous groups watching their departure and arrival. The crowd of would-be riders increases every day, and is far beyond the power of the Company to cope with. No doubt by next year arrangements will be made to increase the number of motor-cars upon the route.

THE Lord Mayor's Show was characterised by the presence of a couple of vehicles—the one representing the uncomfortable lumbering, gaudy, stuffy, jerky, and dilatory stage coach, and the other a motor-vehicle which was capable of carrying more for a greater distance at a higher speed, and with less cost, and with greater care, safety, and comfort than any stage coach ever built. It is, of course, too much to expect that the next Lord Mayor will discard that awfully hideous, lumbering vehicle, called the State carriage, but as the schoolmaster continues to make his influence felt in the coming generation we hope the time is not far distant when carriages in all State processions will be propelled by mechanical means, and that in future Lord Mayors' processions the present State carriage will be exhibited as an example of the kind of State vehicle in use in the unenlightend period of the nineteenth century. However, we must not be ungrateful for the recognition that has been bestowed upon automobilism by the city fathers.

THE *Westminster Gazette* is remarkable for two things—an unreasoning and silly dislike of the Right Hon. Mr. Joseph Chamberlain, the Colonial Secretary, and motor-vehicles. We could understand such an attitude on the part of a professed Tory organ, but it seems just a trifle inconsistent to see a so-called "Liberal" journal adopting it. In a note in a recent number the *Westminster Gazette* says:—"If the arrival of the motor-car and the increase of the cyclists in crowded streets has given the Commissioner of Police in London some anxious moments, the state of the traffic in Paris would be enough to break down Sir Edward Bradford altogether. There the motor-car is daily responsible for a growing list of accidents, for the Paris *cocher* is not at the best a careful driver compared with our London cabby, and when his animal sees one of the monstrous motor-vans bearing down on it, with a noise like a siren, and in a cloud of smoke, its rickety form is galvanised into a wild desire to get into the nearest place of refuge, which may happen to be a shop window or the side of a house. Such pranks are extremely disconcerting, not to say alarming, for the man in the street. The Englishman in Paris who has learnt the terrors of the street will be glad to hear, for the sake of his less experienced fellow-travellers, that the Municipal Council has determined to make inquiries into the question of unrestricted motor-car traffic."

WE are absolutely certain that the arrival of the motor-car has not in the slightest degree caused the Chief Commissioner to have any "anxious moments." Indeed, the suggestion is so childish that it needs no refutation. What, may we ask, *is* a "monstrous motor-van"? Does this refer to size or to some immoral trait in its character? Were the *Westminster Gazette* even tolerably well informed, it would know that the size of motor-vans is strictly regulated by the Police in Paris, and nothing monstrous is permitted; hence a motor-van that made a "noise like a siren" and in a "cloud of smoke," would be promptly seized and the driver rather heavily fined. We might enlarge upon the matter, but our time and space are too valuable to be unduly occupied in refuting every absurd and mendacious statement concerning motor-vehicles that appears in a section of the London Press.

THE Paris correspondent of the *Morning Advertiser* writes:—"If M. Paul Mayan's public statements respecting the almost stationary condition of the automobile car industry here are based upon sound information, the reason for the slow production of those vehicles in France must be sought in the paucity of workmen possessing the requisite mechanical skill. M. Mayan says that the builders have provided themselves with the factories and the necessary machinery, but that a year or two must elapse before the technical training has been disseminated among French artisans to an extent empowering the manufacturers here to meet the active demand for motor-carriages. The French artisan, nevertheless, has been the first in the field, and was engaged in the construction of motor-cars long before the latter were seen in England. A more probable explanation would seem to be that while the French workman is perfectly competent and ready for the work, the French manufacturers themselves are not altogether satisfied with the types of the motor-car yet evolved, and are holding back. An instance of the ingenuity with which this idea of the automobile has been elaborated by the Paris designers and makers has just been furnished by a firm in the Avenue Victor Hugo. The finishing touches are being put in the workshop there to an auto-mobile cottage. The movable habitation thus constructed contains two bedrooms, a dining-room, a bath-room, and a kitchen, with a balcony on the first floor."

OUR contemporary, the *Graphic*, has shown a commendable enterprise in obtaining an electric cab for the use of its staff. Instead of its reporters having to rush hither and thither in noisy and dangerous "hansoms," they now proceed on their business in the swift and secure automotor. Needless to say, the appearance of this cab in Fleet Street has evoked feelings of the most intense jealousy among the journalists. It has been said—we know not with what truth—that since the acquisition of this cab, the *Graphic* men refuse to recognise common journalists who ride in vulgar hansoms. While counselling humility to the scribes of our contemporary, we would suggest that other newspapers might also purchase automotors, and thus remove any chance for what the servant girls call "stuckupness." As regards the performances of the new vehicle, the *Graphic* men speak highly of it. One man writes: "I had the advantage of a long trial of the new vehicle on the occasion to which I refer, and I had experience of its capabilities in crowded thoroughfares, in open roadways, up hill and down dale, and I must say that I was perfectly surprised with the result. The driver seemed to have the most perfect control over his vehicle; the ease with which it could be turned, and the small space it could turn in, the way in which its pace could be moderated, and the quickness with which it could be brought to a full stop, was in the highest degree commendable. One of the drawbacks—which I am told, in time, will be got rid of—is the burr of the machinery. Another is that a different bell should be provided; the present bell is too much like that of the cycle, and when foot-passengers turn round expecting to see a bike and find instead a horseless cab they are naturally somewhat startled. When these two defects have been remedied, one will be able to thoroughly enjoy the ease and the gondola-like movement of the new invention, which ought to achieve a tremendous success."

CONTINENTAL NOTES.

THE De Dion firm has started a line of tractor omnibuses between Melun and Meaux.

A COMPANY is being formed to take over the business of M. Delahaye, the well-known automotor manufacturer. The capital will be 6,000,0 0 francs.

AN association of automobilists for Central Europe has been formed at Berlin, and it rejoices in the name of Mitteleuropaisoher Motorwagen-Verein.

THE municipality of Bordeaux has decided to establish lines of automotor-omnibuses. The London County Council does not know what these things are—apparently.

THE Self-Propelled Traffic Association has become affiliated with the Automobile Club of Paris, and membership of the one carries honorary membership of the other.

HERR THIEN, a Berlin electrician, has built an electric drosky, which will go 42 miles, on one charge, at a speed of 13 miles an hour. The accumulators are of the Currens type.

IT is said that an English firm has taken premises at Puteaux for the manufacture of electric automobiles, capable of going 120 miles without recharging. We should like to see that cell. By the way, Puteaux has been christened by *Les Sports* Automobilopolis.

SINCE the French Government has decided to tax motor-vehices on the pretence that they are articles of luxury, why, it is asked, should not yachts be taxed? The answer is simple, the French Government is extremely desirous of doing all it can to increase its naval strength, and actually gives bounties to shipbuilders and shipowners.

THE French military authorities have recently put the "Scotte" tractors through some very severe trials in hauling baggage, wagons, cannons, &c. The experiences have been most satisfactory; the military men are loud in their praises of this new adjunct to warlike operations, and it is certain that automotor vehicles will ere long form an indispensable part of the equipment of every modern army.

LES POIDS LOURDS.—After a somewhat lengthy delay the commission appointed by the Automobile Club to conduct Les Poids Lourds trials has issued its report. The report is a compendious volume of 55 pages, and it contains a large amount of useful matter. We shall deal fully with it in our next issue. M. le Comte de Chasseloup-Laubat is to read a paper on the trials at one of the meetings of the Société des Ingénieurs Civils.

IT will be remembered that on the occasion of the Paris-Dieppe race the special train broke down, and the intention was expressed of claiming an indemnity. That there was a good cause for action is apparent when it is remembered that the special train arrived after the race had been run, and thereby defeating the very object for which the "special" was chartered. The indemnity agreed upon was 10,000 francs, which has been paid to the Automobile Club.

M. MICHELIN has furnished some particulars to *La Genie Civile* as to the cost of running a steam brake, using coke as fuel and carrying six persons. The weight of the brake is 2,050 kilos. = 4,510 lbs. tare. It has journeyed over 7,700 kilometres, or 4,774 miles, and the cost works out at—for coke, ·0616 franc per kilometre, oil for lubrication, ·0346 franc per kilometre, and total cost of running, ·1065 franc per kilometre. The mean speed was 16 kilometres, or 9·6 miles per hour. The repairs are put at 50 francs per month.

ALEXANDRIA, which was the home of a high civilisation when London was an uncouth collection of mud huts, and which boasted of fleets and libraries when British naval architecture was represented by coracles made of wattles sheathed with skins, still maintains its ancient reputation. It has a modern and fully equipped electric tramway system. London is content with a wretched system of horse-drawn tramcars. We would suggest that a deputation of members of the London County Council should visit the ancient seaport of the Pharaohs and see how it's done.

MR. PENNINGTON is, perhaps, hardly sufficiently appreciated on this side, but in France he has at any rate succeeded in arousing the enthusiasm of *Les Sports*, which paper thus pours itself out:—"Pennington the great, the illustrious Pennington, he who has invented the war automobile," and so on, and so on. *Les Sports* then goes into raptures about the magnificent apartment which this distinguished gentleman occupies at the Grand Hotel, and loses itself over the contemplation of the boxes of cigars and the bottles of champagne produced.

OUR French friends have a genius for taxation. Is there any single article of commerce in France which is not taxed in some way? We think not. So long as motor-vehicles were in the experimental stage they escaped taxation, but a vigilant Minister of Finance had got his eye upon them, and when he saw that they were articles of regular manufacture and employed for commercial purposes, he, worthy gentleman, issued his decree, and in future automotor-vehicles with two places will pay 60 francs, and the others 100 francs; in communes of more than 40,000 inhabitants they will pay 40 francs and 75 francs respectively; in communes of from 20,000 to 40,000 inhabitants, 30 francs and 60 francs; in communes of 10,000 to 20,000 inhabitants, 25 francs and 50 francs; in communes of 5,000 to 10,000 inhabitants, 20 francs and 40 francs; in communes of less than 5,000 inhabitants, 10 francs and 20 francs.

THE reason for the imposition of the tax is that the Finance Minister is 30,000,000 francs to the bad in his Budget, and hence there is some excuse for it. At the same time, we fail to see why the residents of large towns or districts should be discriminated against in favour of those who reside in the small ones.

SOME time ago the French Minister of Public Works appointed a Commission to discuss the condition under which services of public motor-vehicles should be subsidised by the State. The Commission has reported that the State is authorised by law regulating public transport to pay subsidies to automotor companies subject to an engagement not exceeding a period of 10 years. Subsidies, however, can only be granted to companies possessing sufficient rolling stock to be able to carry daily over the whole length of the system at least 10 tons of merchandise at an average speed of four miles per hour, and of 60 passengers with two tons of luggage at an average speed of seven miles. The subsidy for each year is calculated according to the total distance covered by the vehicles, and their capacity for carrying passengers, luggage, merchandise, and the like. The amount cannot exceed 250 francs for every kilometre of road comprised in the daily service, or be more than half of the total subsidy allowed by the departments or the communes. Nevertheless, it can attain 300 francs and 350 francs per kilometre, and the three-fifths and two-thirds of the total subsidy respectively in departments where the amount received in taxation does not exceed a certain figure, that is to say, districts which are only poorly or sparsely inhabited. The report is very generally approved in Parliament.

Automotor Cabs in Paris.—The Paris correspondent of the *Daily Telegraph* writes:—The London electric cab that was recently sent over to Paris has been tested with success. It has been taken up the steepest hills, has made the round of Paris, has created no little sensation among the promenaders in the Bois de Boulogne, and has exceeded the 70 kilometres agreed upon with a run of 80 kilometres, after which its motive powers were moreover not exhausted. Representatives of some of the principal companies and a number of engineers have followed these experiments with equal interest and delight, and the problem of ways and means is being attentively studied. It is believed that something can be done towards reducing the weight of the vehicles, nor will the entire cab system be revolutionized at once. A certain number of these cabs will be started as an experiment, and if the public, as is expected, takes kindly to them, they will be rapidly increased. It is affirmed, by the way, that the reason why more horseless vehicles have not been brought out in Paris is that the manufacturers have great difficulty in procuring the requisite amount of skilled labour, so that all the local builders together do not produce between them at the rate of more than one horseless carriage a day.

An Electric Delivery Wagon.—Our American contemporary, the *Electrical Age*, gives an illustrated description of an electrically-propelled delivery wagon constructed by a Chicago firm. The electrical equipment consists of 44 storage batteries, having an individual capacity of 100 ampères per hour, weighing only 13 lbs. each, and connected with a 3½ H.P. motor, iron-clad and waterproof, of the four-pole pattern. The charging apparatus consists of an automatic stationary rheostat, which is equipped with meters indicating the proper volume of current and the number of ampères stored in the vehicle batteries. These have an apparatus which automatically disconnects them from the charging circuit when fully charged. The plugs of the connections, the binding posts of the batteries, and the rheostat are correspondingly marked positive (+) and negative (−), so that no possible error can be made in placing them. The guiding lever is at the driver's left hand, and a smaller lever at the seat on the right reverses the machinery. The wheels bear on frictionless ball-bearing axles, and have three-inch pneumatic tyres. One of the wheels carries an odometer, and this has proved that as great a distance as 64 miles has, under favourable circumstances, been run with one charging of the batteries. The batteries occupy very little space, and they can, therefore, be so placed as not to injure the appearance of the vehicle. It is stated that from the odometer record it has been found that the electricity costs about one halfpenny per mile. The wagons register from 30 to 42 miles a day each, and even then the batteries are not half empty at night.

Military Automotor Vehicles.—The Paris correspondent of the *Daily Telegraph*, writes:—"Military authorities in this country cannot be accused of neglecting to turn recent inventions to profitable account. Cycling has been encouraged in the army to a considerable extent, and now it is the motor-car which is claiming its share of attention. With a view to ascertaining how it could be utilized for the transmission of communications at a rapid rate and over long distances, Général Billot, Minister of War, has just got up a very practical experiment, which has been duly carried out by a committee of officers, under the direction of Colonel Feldmann. Two hundred kilometers were to be covered between dawn of day and night, with an hour's interval for rest. Such was the programme, and the worst roads that could be pitched upon were expressly selected for the purpose. The start was effected from the Place St. Thomas d'Aquin, between 6 and 6.30 a.m. Eight vehicles were pressed into the service, and the majority of them conveyed specially appointed delegates, among whom may be mentioned Captain Mangin, Commandant Sainte Claire-Deville, Captain Barisier, and Captain Parra. With the exception of one, all the cars were provided with motors of six-horse power. Each vehicle followed a separate road, there being three equidistant convergent points: to wit, Dreux, Fontainebleau, and Villers-Cotterets. Among the drivers of the cars were M. René de Knyff, Mr. Archdeacon, and Mr. Morse, and all were delighted with the expedition, which, moreover, gave the officers complete satisfaction. The roads were as bad as could possibly have been wished, and any amount of skill was needed to deal effectively with the obstacles which presented themselves on the various routes. The military committee has since visited the establishments of the chief constructors, in order to study the different types of vehicles under the superintendence of Colonel Feldmann.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

LIVERPOOL AND DISTRICT CENTRE.

President of the Association: Sir David Salomons, Bart.

LIVERPOOL CENTRE.

President:

The Right Honourable The Earl of Derby, K.G., G.C.B.

Vice-Presidents:

H. Percy Boulnois, M. Inst. C.E.; Alfred Holt, M. Inst. C.E.; Alfred L. Jones, J.P.

Members of Council:

Trials of Motor Vehicles for Heavy Traffic, May, 1898.

PARTICULARS OF COMPETITION.

(Issued by the Liverpool Centre and approved at Head Centre.)

Objects of Trials.—The chief object of the trials is to arrive at a type of heavy motor-wagon suitable for trade requirements in Liverpool and neighbourhood, which shall be capable of economically taking the place of horse haulage and of competing with the existing railway rates, in the transport of heavy loads of goods over considerable distances.

Nature of Trials.—Trial runs will be made from Liverpool, over minimum distances of 30 miles, on four successive days. All vehicles will be required to traverse the prescribed routes, without alternative, and to perform such manœuvres as are hereinafter specified. No route longer than 40 miles will be selected.

Route-maps will be issued for each course on the mornings of the respective runs.

Date of Trials.—The trials will begin on the morning of Tuesday, May 24th, 1898, and will conclude on the afternoon or evening of the Friday following.

Judges.—Three members of the Liverpool Council and two members of the General Council will be chosen by their respective Councils to act as judges. As soon as these gentlemen have been appointed their names will be published.

Awards.—Money prizes of £100, £75, and £50, also certificates of merit, will be given at the discretion of the judges.

A full and exhaustive report on the trials will be issued by the judges and circulated by the Association.

Intending competitors are also referred to the special notice below.

General Regulations Applicable to all Vehicles.

(I.) The vehicle shall be self-propelled. The part carrying the generator or motor, or both, may be articulated and detachable, but the propulsion shall be effected by utilising the load for adhesion.

(II.) The vehicle shall be propelled by mechanical power alone, but (with the reservation that the judges may disqualify and prohibit from competition any vehicle or motor which, in their opinion, is faultily constructed or dangerous from any cause whatever) there shall be no restriction on the source of such power or the nature of the agents used.

(III.) The vehicle shall be capable of going anywhere that a horse-drawn vehicle carrying the same load can go, and of being placed in the same positions and withdrawn therefrom without external assistance.

The particular manœuvre most generally called for is to work into and out of a loading berth when "cramped" for room. This requirement arises in the case of embayments, or of confined spaces between other vehicles in a line receiving or discharging goods. Carters usually back into such positions obliquely, and bring the vehicle into line by turning the leading wheels at right angles to the rear wheels and again backing.

(IV.) The vehicle shall be capable of working into and out of an embayment of one-and-a-half times its own length.

(V.) The vehicle shall conform in all respects to the requirements of the Locomotives on Highways Act, 1896, and, in the case of its being oil-propelled, of the "Regulations as to Petroleum," issued by the Home Secretary under Section 5 of this Act.

(VI.) All working parts shall be properly encased.

(VII.) The tare of the vehicle shall be recorded, both inclusive and exclusive of any water, fuel, or accumulators used for the purpose of propulsion.

Vehicles Eligible for Competition.

Class I.—Vehicles capable of carrying a minimum load of two tons of goods. (Vehicles entered in this class may be open or covered.)

Class II.—Vehicles capable of carrying a minimum load of five tons of goods. (Vehicles entered in this class shall have level platforms only without any covers.)

Regulations Applicable to Vehicles According to Class.

(I.) The average speed during the trial runs, inclusive of stoppages, shall reach—

(*a*) In Class I, six miles per hour.
(*b*) In Class II, four miles per hour.

(II.) The vehicle shall have a level platform area of not less than—

(*a*) In Class I, 60 square feet.
(*b*) In Class II, 110 square feet.

(III.) In Class II the height of the floor line from the ground shall be not less than 3 feet 9 inches, and shall not exceed 4 feet 3 inches.

RULES AND CONDITIONS.

(I.) The vehicle shall carry at least the minimum weight of goods, or any weight in excess declared by the competitor, throughout the continuance of the trials. Suitable ballast will be provided by the Association.

(II.) Each competitor shall himself make all arrangements for the necessary staff and appliances to work his vehicle or vehicles. Accommodation for the vehicles, in Liverpool, will be provided by the

Association. Vehicles intended for trial shall be registered as "arrived," at this depôt, not later than 3 p.m. on Monday, May 23rd, 1898.

(III.) An official observer will accompany each vehicle during the trial runs, to take notes of behaviour, fuel and water consumption, &c., and no repairs will be permitted without his knowledge and consent.

(IV.) Any vehicle withdrawn from competition during the trials, except under the written authority of the judges, shall not be eligible for a prize or for commendation.

(V.) Six photographs of each vehicle, together with one perfect negative, shall be furnished by the competitor, not later than May 16th, 1898.

These must be delivered in good order at the Liverpool Royal Institution, addressed to the Honorary Secretary, Self-Propelled Traffic Association.

(VI.) Full drawings of any vehicle shall be submitted to the judges in confidence, if required by them, prior to the final adjudication.

(VII.) Entries shall be made on printed forms (to be obtained from the Honorary Secretary) at any time prior to 12 noon on the last day of March, 1898, and shall be accompanied by an entrance fee as under:—

	£	s.	d.
For one vehicle	5	5	0
For each additional vehicle by the same competitor	1	1	0

Entries shall be addressed, under cover of a registered letter, to the Honorary Secretary, Self-Propelled Traffic Association, The Royal Institution, Colquitt Street, Liverpool.

(VIII.) A complete list of particulars shall be lodged with the Honorary Secretary not later than May 16th, 1898.

The description must be type-written or printed, and six copies must be furnished. The tare weight of the vehicle, both exclusive of any water or fuel and in complete running order, must be given, also, as briefly as possible, any peculiarities of construction or of working to which the competitor desires to draw the attention of the judges.

(IX.) Each competitor shall arrange to have his vehicle or vehicles ready for inspection by the judges at 9 a.m. on the morning of Tuesday, May 24th, 1898, in the depôt that shall be used as head-quarters during the trials.

(X.) All vehicles shall be stored over-night at the depôt or depôts provided by the Association.

(XI.) Lots will be drawn to determine the order of starting. It is intended to begin the runs shortly after 9 a.m. on each of the four days, the vehicles following one another at intervals of about 10 minutes.

(XII.) At the conclusion of the trials, any vehicle, or motor, or part thereof, shall be opened up, in confidence, for inspection by the judges, if required.

The judges reserve to themselves the right of absolutely disqualifying any competitor for any infraction of these rules.

While obeying in all respects the instructions of the judges and the conditions of the competition generally, it is to be fully understood and agreed by every competitor that no responsibility, legal or otherwise, is to attach either to the judges or to the Self-Propelled Traffic Association, in respect of anything, or for any damage or injury caused to any person or thing, but that all responsibility of every sort and kind, whether pecuniary or otherwise, is to attach to the competitor, and is to be borne by him.

THE FOLLOWING ARE THE POINTS WHICH WILL BE TAKEN INTO CONSIDERATION BY THE JUDGES IN MAKING THE AWARDS.

(a) *Cost.*—Economy of working, including attendants.

(b) *Control.*—Stopping, starting, changing speed, steering and reversing, particularly under adverse conditions, such as on inclines or in confined spaces.

(c) *Working.*—Noise, smell, visible vapour, dust, or other nuisance when travelling; number of mechanical operations requiring attention from the driver; efficiency of brakes; time occupied in preparing the vehicle for service on the road; ability to start from rest on an incline of 1 in 16; speed—within legal limits; distance run without taking or receiving supplies of fuel, oil, gas, electrical or chemical materials or electrical current, water, or of any agent employed for actuating the motor or assisting its working; ability to complete the course without stopping to effect repairs, adjust parts, apply lubricants, or for any other purpose or cause not provided for in the itinerary; freedom from a break-down of any nature.

(d) *Construction.*—Strength of frame and working parts; quality of workmanship; efficiency of springs; freedom from complicated or over-refined parts; facility with which repairs can be effected; capacity of bunkers, oil and water tanks; ratio of available to total platform area—preference will be given, as regards vehicles entered in Class II, to a system that gives the entire platform, from end to end, free for goods; ratio of tare to power of motor; ratio of tare to weight of freight carried during the trials.

(e) *Steam-propelled Vehicles.*—Action of feed-pumps or injector; ample supply of steam; consumption of fuel and water per mile; leakage of steam or water; arrangements for stoking.

(f) *Oil-propelled Vehicles.*—Efficiency of ignition; regularity of carburation and explosions; range and gradation of speed of vehicle, and smoothness with which changes of gear are effected; circulation and weight of cooling water; consumption of oil per mile; leakage of pipes or tanks.

The decision of the judges, expressed in writing on any point, shall be final and binding on all parties, and they may withhold any award, or any portion thereof.

Three printed copies of these rules will be issued with each form of entry, one of which, signed by the competitor, must accompany each entry when forwarded to the Honorary Secretary. In signing and returning this copy of the rules, the competitor shall accept all the conditions herein imposed upon him, and shall agree to be bound in all respects by them.

Each vehicle will be allotted an official number which must be displayed during the continuance of the trials.

LAWRENCE JONES, Honorary Solicitor.
E. SHRAPNELL SMITH, Honorary Secretary.

Royal Institution, Liverpool,
November 16th, 1897.

SPECIAL NOTICE TO COMPETITORS.

A prominent member of the Association has intimated to the Honorary Secretary that he is willing to receive, on the recommendation of the judges, one or more vehicles to work in the heavy goods traffic of Liverpool and neighbourhood, on trial, during a period of one month, and, further, that he is prepared to purchase fifty vehicles in all.

Provided—

(a) That the vehicle shall carry five tons of goods during the official trial runs, and that it is capable of carrying up to ten tons when required.

(b) That the vehicle shall comply with the regulations applicable to Class II.

(c) That during the month's trial, the vehicle shall work generally to his satisfaction.

(d) That during the month's trial, the cost of working shall not exceed 3·5*d.* per net ton-mile, calculated on the basis set forth below.

During the continuance of these additional practical trials, the expenses of working, up to 3·5*d.* per net ton-mile, will be borne by the member in question.

This offer is not to be taken in any sense as a contract of a binding nature at law.

SCHEME [referred to in Provision (*d*)] FOR ASCERTAINING THE COST OF WORKING.

The cost of working per net ton-mile, inclusive of interest at 5 per cent. per annum, depreciation at 15 per cent. per annum, maintenance, attendance, and all other charges shall not exceed 3·5*d.* This cost shall be calculated on the basis of 60 per cent. of maximum load (10 tons) being carried 15 miles per day, and the same distance being traversed "light" (*i.e.*, without load), on 260 days per annum. An example of the method of calculating this figure is appended:—

Load designed for	5 to 10 tons.
Active work per annum	260 days.
Distance traversed with 60 per cent. of load (6 tons)	3,900 miles.
Distance traversed light	3,900 miles.
Prime cost, say	£600.

Assumed Expenditure.

		£ s. d.
Interest at 5 per cent. per annum, say		30 0 0
Depreciation at 15 per cent. per annum, say ..		90 0 0
		120 0 0
*Fuel—13 lbs. of furnace coke per vehicle-mile, 13 lbs. × 30 × 260 = 45 tons at 15s. per ton	33 15 0	
*Oil, grease, and waste	10 0 0	
*Wages—Driver at 30s. per week ...	78 0 0	
Boy at 7s. 6d. per week ...	19 10 0	
Stabling—Proportion	5 0 0	
*Water	10 0 0	
Licence	5 5 0	
*Repairs	20 10 0	
		182 0 0
Total per annum		£302 0 0

TRAFFIC—
6 × 3,900 = 23,400 net ton-miles.
Cost = 3·10d. per net ton-mile.

* Cost determinable during the month's trial.

The Second Session of the Self-Propelled Traffic Association (Liverpool Centre) will be opened at 8 p.m. on Friday, November 26th, when the President of the Association, the Right Hon. the Earl of Derby, K.G., G.C.B., is expected to take the chair. The meeting will be held at the Royal Institution, Colquitt Street, Liverpool. The inaugural address—"Self-Propelled Vehicles, 1896-7" (with lantern illustrations)—will be delivered by Mr. W. Worby Beaumont, M. Inst. C.E., M. Inst. Mech. E., Cantor Lecturer on Modern Road Vehicles, and Member of the General Council of the Self-Propelled Traffic Association. The hon. President during his visit upon this occasion will be the guest of Mr. Alfred L. Jones.

London Cab Fares.—A writer in the *Daily Telegraph*, discussing the question why cabs are dear, says:—"But the great recommendation of the omnibus is its cheapness; and the great drawback to the cab is its admitted dearness. Moreover, taking the cab system of the metropolis and contrasting it with the facilities obtainable abroad, or even in our own provincial cities, the deficiencies of London are at once apparent. The real trouble rests in the difficulty of adjusting fares, and herein lies the whole secret of the failing tendencies of the cab trade. It wants a person having the courage of his convictions to pay a cabman no more than his legal fare, and it is only a man who knows his London well who would dare to dispute, at the risk of being publicly insulted in the streets, cabby's dictum as to distances. Many men, rather than incur odium of the kind, wilfully pay the driver much more than his due, and thus encourage him to expect the next fare to be equally liberal; whilst many ladies, rather than pay more than is just, avoid the cabman altogether, and thus it happens that his custom diminishes and his prospects tend to grow more gloomy, with the keener omnibus competition, and that of the network of underground railways already in existence, or now in course of construction. It may also be recollected that the new electric cabs have come to stay. In the view of competent judges they are doing very well, and it is expected that as the winter approaches these weather-protected coaches will be preferred to hansoms. The advent of the electric cab, it is no secret, is necessitating an entire revision of the regulations applying to licensed public carriages, but the Secretary of State and the police have no power whatever to revise fares, and only a magistrate can settle a dispute as to any hiring. Recent alterations in the law, by what is called the Bilking Act, no longer oblige a cabman to drive his fare to a police-station, should any quarrel arise between them. But in the interests of the public, and if cabs are to continue to exist as licensed vehicles, reform is demanded; and it is argued that the electric cab proprietors, as they become firmly established, instead of falling into the old rut and letting out their cabs, as though they were hansoms or 'growlers,' at a daily charge, might take steps to obtain the Parliamentary revision of cab fares. In the best informed quarters motor-cabs are expected to bring about a reduction of fares, and it is also thought that the four-mile radius must shortly be extended to five. If cabs could be run as 'buses or trams then a charge by distance, as recorded by the cab itself, could be made."

AN IMPROVED DIFFERENTIAL GEAR FOR MOTOR-VEHICLES.

Mr. R. Jas. Urquhart, C.E., of Liverpool, has effected several improvements in ordinary differential or "Jack-in-the-box" gear, which we herewith illustrate and describe.

His invention relates to differential reducing gearing for the high-speed engines of automobile vehicles, and consists in improvements in the construction and arrangement of such gearing which embodies an epicycloidal train, the object being to produce a compact gearing from which can be obtained several reduced speeds in both directions without reversing the direction of the primary shaft. In the arrangement illustrated the primary shaft drives the secondary or low-speed shaft through an epicycloidal train, which may gear directly with the primary shaft or indirectly by means of intermediate gearing. One element of the epicycloidal train is fixed so as to drive the low-speed shaft; this is the carrier which carries the intermediate or planet pinion or pinions. The other two elements of the train are so arranged that they can be driven from the primary shaft in both directions.

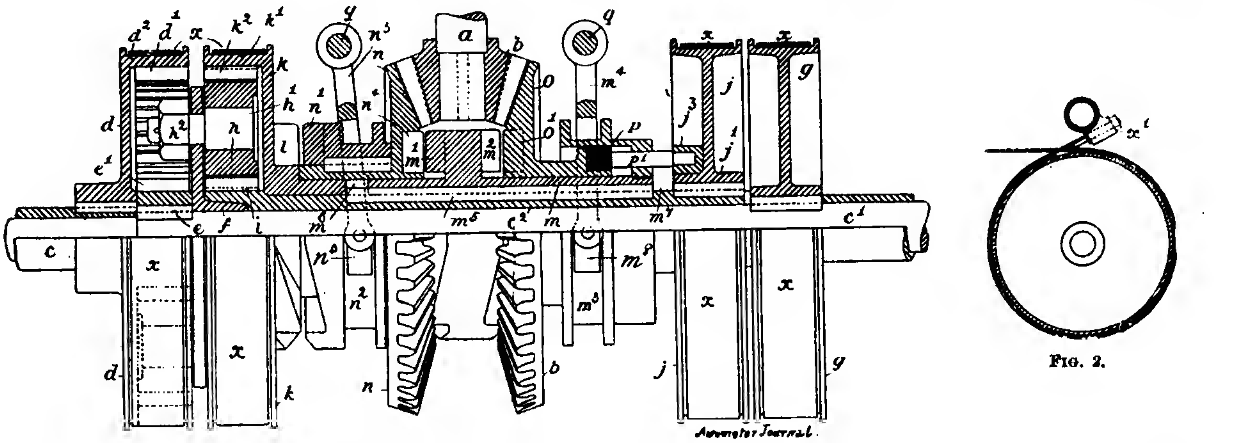
Each of the two elements driven from the primary shaft is provided with a brake drum and band or equivalent friction clutch, by which it can be fixed or allowed to slip at will. When it is required that the primary shaft shall continue to rotate without the epicycloidal train, the primary shaft is provided with a suitable clutch or clutches by which such train may be driven or not as desired. The elements of the train are the two differential wheels and the planet wheel.

The accompanying drawings illustrate the best method of construction of the improved arrangement of gearing. Fig. 1 illustrates an elevation of the gearing showing the upper half or so in section. Fig. 2 shows the method adopted of securing or fixing the two elements of the epicyclic train to prevent their rotation and checking their rotation. In the arrangement illustrated, bevel gearing is employed to rotate the two elements of the epicycloidal train, the latter being preferably formed with spur wheel teeth. The arrangement is also shown as applied to the axle of two driving wheels of a road vehicle, and as driving through a differential or balance gear to allow of one wheel over-running the other when the vehicle is passing round a curved path.

Referring now to Fig 1, a is the high-speed shaft, and it may be the motor-shaft or a shaft in direct gear with the motor-shaft. In many cases it will only rotate in one direction, but in some cases it will be required to rotate in either direction. When it is required to rotate in either direction the motor is provided with reversing gear or the shaft, d, is driven from the motor through a reversing clutch arrangement. The bevel pinion, b, is keyed to the shaft, a. The travelling or driving wheels' axle is in two parts, c and c^1; to each part is keyed one of the travelling wheels. To the part c is keyed the element, d, of the differential or balance gear, which is preferably formed with spur teeth. To the part c^1 of the axle is keyed the spur pinion, e, and freely on the axle is mounted a carrier or disc, f, upon which are mounted a stud or studs. Each stud carries a spur pinion which gears with the teeth, d^1, of the element, d, and the teeth, e^1, of the element, e, at the same time.

The element, d, of the balance gear is provided with a flanged rim, d^2, fitted with a band brake, x, of ordinary construction, the band of which is fixed at one end, x^1, Fig. 2, to the structure carrying the gearing, and at the other end is attached to any suitable lever arrangement by which it can be drawn tightly round the flanged rim. By so gripping this part of the balance gear, the travelling wheel fixed to the part, c, of the wheel axle can be braked. The part, c^1, of the axle to which is fixed the second travelling wheel, is also provided with a flanged rim or pulley, g, fitted with a brake band, x, operated in a similar manner. The two brake bands are preferably so coupled together by rods and levers that they operate in unison.

The elements of the epicycloidal train are arranged that the angular speed of the last or driven element, f, has the lowest value. The element, f, forms the carrier for the planet wheel, h. Preferably three planet wheels are arranged round the disc, f. Each planet wheel, h, is carried upon a stud, h^1, fixed to the disc, f, preferably by a screwed nut, h^2. The element, i, or sun wheel of the epicycloidal train is mounted free upon the part, c^1, of the axle and has a long sleeve, c^2, at the end of which is keyed a flanged brake pulley, j, fitted with a suitable band brake, x, similar to those fitted on the flanged rims, d^2, and g^2, or other suitable known form of clutch, and by which it may be prevented from rotating or checked to the desired extent. The element, k, of the epicycloidal train is preferably mounted upon the sleeve, c^2, so as to revolve freely thereon. It is also provided with a flanged rim, k^1, and a band or other friction brake by which it may be held stationary or allowed to revolve at will. The internally cut teeth, k^2, are in gear with the pinion or planet wheels, h. A clutch box, l, is also formed on the element, k, by which it is rotated. A sleeve, m, provided with clutches, m^1 and m^2, is mounted upon the sleeve, c^2, and is provided with a shipping collar, m^3, and forked shipping lever, m^4. The sleeve, m, is fixed so as to rotate with the sleeve, c^2, by the key or feather, m^5, but is capable of a sliding movement in the line of the axle or shaft, c^1, spaces, m^6 and m^7, being provided as clearance. Upon the sleeve, m, are loosely mounted two toothed bevel wheels, n and o, in gear with the toothed bevel pinion, b. Each of these bevel wheels is provided with clutch boxes, n^4 and o^1. A clutch, n^1, is also keyed to the boss of the wheel, n, to rotate therewith but free to slide lengthwise thereon. This clutch is provided or formed with a shipping collar, n^2, and shipping forked lever, n^3. In order to keep the bevel wheel, o, in gear with the pinion, b, a collar, p, is fitted loosely upon the end of the boss of the bevel wheel, o. A similar loose collar, j^3, is also fitted upon the boss, j^1, of the pulley, j, the two collars are fixed together by rods, p^1, passing through openings formed in the collar, m^3. The shipping levers, n^3 and m^4, are fixed to rods, q, which are moved by hand levers or



IMPROVED DIFFERENTIAL GEAR.—FIG. 1.

FIG. 2.

equivalent means. The clutches, n^1, m^2, and m^1, and the corresponding clutch boxes, l, n^4, and o^1, are formed in the case illustrated to drive each in one direction only, but in other cases when the same speeds are required when travelling in either direction the clutches and clutch boxes are formed accordingly. Sliding boxes, m^8 and n^5, are disposed in the grooves of the shipping collars, m^3 and n^2, and the forked ends of the shipping levers, m^4 and n^3, are pivoted to them. Also when the element, k, is free to rotate through its brake drum, k^1, not being clutched and the element, i, is driven through the clutch, m^1 or m^2, being in gear with the bevel wheel, n or o, or when the element, k, is driven through its clutch, n^1, and the element, i, is free to rotate through its brake drum, j, not being clutched, the gearing may rotate without communicating motion to the shaft or axle, c^1. If, however, the elements, k and i, be clutched to the bevel wheel, n, so as to rotate therewith an aggregate speed in the disc, f, or the same as that of the bevel wheel, n, is obtained; but by clutching the element, i, to the bevel wheel, o, so as to rotate therewith a certain differential speed of the disc, f, is obtained. According to this arrangement of gearing two further different speeds of the disc, f, in one direction can be obtained, first by clutching the element, k, to the bevel wheel, n, and fixing the element, i, by its brake drum, j, and, secondly, by clutching the element, i, to the bevel wheel, n, through the clutch, m^2, and fixing the element, k. Also the disc, f, can be made to rotate in the opposite direction by fixing the element, k, and clutching the element, i, to the bevel wheel, o. It is obvious that in some cases the balance gear can be dispensed with, as when one travelling wheel only is driven, in which case the element, f, is fixed directly to the hub or axle.

The claim made by the inventor is the improved construction of gear for transmitting the motion of a shaft rotating at a uniform angular speed to produce certain reduced angular speeds in the travelling wheel or wheels of a vehicle in both directions substantially as described and illustrated in the drawing.

The specification is numbered 19,559 of 1896.

LAW REPORTS.

J. R. FREEMAN, of J. R. Freeman and Sons, cigar manufacturers, Hoxton, was, at the City Summons Court, on November 5th, fined 10s., including costs, for causing a motor-van to be used without having the name and address of the owner painted on it according to law.

ON the 10th inst., before Mr. Justice Wright, sitting as an additional Judge of the Chancery Division for the purpose of hearing petitions for the winding-up of companies, a petition was presented by Mr. E. R. Evans, a shareholder, for a compulsory order to wind up the Ward Electrical Car Company (Limited). The Company was formed in 1888. It had, said counsel, never done any business, never owned any omnibuses, nor had any commercial existence. There was no opposition, and his lordship made the necessary order for winding up the Company.

THE petition of Messrs. J. K. and R. Lord for an order for the compulsory winding-up of New and Mayne (Limited), of London, electrical engineers, was before Lord Justice Vaughan Williams recently, in the Companies' Winding-up Court. Mr. Baker appeared for the petitioners, and explained that they were judgment creditors for £159 11s. He had received support for the petition from eight other creditors, but no notice of opposition, except from the liquidator and the debenture-holders. Mr. Hamilton, who appeared for the liquidator, asked that the petition should stand over until there had been held a meeting of the creditors to consider a scheme of arrangement. The liquidator would show that if there was a forced sale of the property, the unsecured creditors and the shareholders would receive nothing; whereas if the scheme of reconstruction were entered upon, not only the creditors would be paid, but the shareholders would also benefit. The further hearing of the petition was then adjourned until the first petition day after November 10th.

ON the 8th inst., at Highgate Police Court, Bernard Boverton Redwood, residing at Slewathen, Ballard's Lane, Finchley, was charged on a summons with driving a light locomotive—viz., a motor-tricycle—and refusing to stop when called upon to do so by Police-constable Coe, 101 S. Mr. Paterson, solicitor, defended. Coe deposed that at 12.30 p.m. on Sunday, October 24th, he was on duty in Ballard's Lane, Finchley, when his attention was called to a horse attached to a landau which had bolted down the lane. He succeeded in bringing it to a standstill, and was trying to quiet the animal down when the defendant approached from behind on a motor-tricycle. Witness held up his hand and called on defendant to stop, but he took no notice, and, in passing the horse, frightened it again. Jonathan Hunt, a coachman, said that he was engaged to take a customer home from chapel on the day in question. He was waiting outside the chapel when defendant passed him on a motor-tricycle. His horse was frightened, but, notwithstanding that, he passed him four times. The fourth time the motor-car caused the horse to bolt. The policeman and a man named Bell stopped the horse, after the horse had smashed the fore-carriage of the landau. Whilst the horse was being held by Coe the defendant rushed by again, and refused to pull up when called upon to do so by the policeman. Dr. Orton told defendant that the full penalty was £10, but, as this was the first case of the kind brought before the Court, the defendant would be fined 20*s*. and costs only.

REVIEWS OF BOOKS.

We have received No. 1 of Vol. XVII of *The Indiarubber World*, which abounds in well-written matter of great interest to trade readers.

We have also received the *Journal of the Western Society of Engineers of Chicago*, which contains, among other useful matter, a paper on "Causes of the Variable Efficiency of Steam Boilers and their influence on Tests."

The Carriage Monthly (Philadelphia) is, as usual, worth the attention of carriage builders. Some novel and well-worked out designs of typical American vehicles are given, accompanied by working drawings and specifications. A new motocycle by the Block Manufacturing Company of Indianapolis is illustrated and described, and there are also some good articles on varnishes, colours, &c.

"Birch's Manual of Cycle Companies."—This is the first edition of what will doubtless prove a "hardy annual." That a good work of this kind is needed is apparent when we consider that at the time of publication there were no less than 223 Limited Companies, having an authorised capital of £30,000,000, engaged in the cycle industry. At the present time this amount has been largely increased by the formation of other Companies. The work before us comprises a list of companies, giving the names of directors, officers, capital, dividend, &c. This is accompanied by an index, so as to facilitate reference. There is also a chronological list of registrations, and a directory of directors' officials. A chapter is devoted to the law of cycles and motor-vehicles, and another to patents. The imports and exports of, and duties levied on, cycles and their component parts follows, and a copious index concludes the volume. The work is well arranged, and the printing, &c., excellent; but the list of motor companies is sadly deficient.

The Thames Ironworks Quarterly Gazette.—This quarterly is to hand, and, as usual, it abounds with instructive matter for all connected with nautical automobilism, but is more interesting to those connected with the great shipbuilding works on the Thames. There is a good account of the career of the unfortunate H.M.S. "Captain," contributed by that veteran naval designer, Mr. G. Mackrow, who has, next to Sir W. H. White, designed more warships than any other man living, and remarkably good ships they have proved themselves to be. This gentleman also describes the final departure of his latest creation, the Japanese battleship "Fuji," and excellent photographs of this vessel and the "Captain" are given. A good picture is that of the Queen reviewing the Baltic Fleet in 1854 from the yacht "Fairy," also built at this historical shipyard. It is not generally known that this Company, the "Thames (Limited)," as it is usually designated, is a centre of light in the East End. Mr. A. Hills, the chairman, is a model employer, and strikes are unknown under his rule. There are science classes and cricket and football clubs in connection with the works, while the encouragement of thrift is a great feature. Savings-bank, medical, and other clubs, are established, to which all have to belong. We have only one wish for the "Thames (Limited)," and that is, may its yard be full of work!

The Engineering Magazine for October contains no less than ten original articles on subjects which are just now largely occupying the attention of the capitalist, the engineer, and the general public. Professor Geo. Forbes discusses the problem of electric power for trunk-line railways. After referring to some early American lines, the professor says:—"It can be proved that if the railway companies of Scotland were to combine to work their trunk lines by means of electric locomotives, the electric current being developed by the water power which exists in that country, then the whole of that service might be carried on without the use of steam locomotives." This is a direct statement, and no doubt Professor Forbes has not made it without due consideration. If we accept it, then it follows that the Scottish railway directors are neither studying the interests of their shareholders nor the public. Few people are more conservative than railway and tramway directors, and they really seem to think that a locomotive and a two-horse tramcar represent the most perfect means of locomotion. As showing the advantages of electric traction, Professor Forbes gives the following particulars:—The cost of running the City and South London Electric Railway is 6·48*d*. per train mile; that of running the Liverpool Overhead Railway is 3·84*d*. per train mile; while the Metropolitan District Railway is 11·76*d*. per train mile. "Modern Wharf Improvements," by Foster Crowell, is interesting in view of the present crude methods of loading and discharging vehicles in London. One hundred years ago wagons were backed up against the street kerb—just as they are now, and brewers lowered their casks of ale into publicans' cellars by means of a rope stretching across the pavement—just as they do now. One has to go to a port such as Marseilles or Hamburg to see how freight can be and ought to be handled. In Liverpool and London the art is not known or imperfectly understood. "The Enormous Possibilities of Rapid Electric Travel," by Messrs. Charles Davis and F. S. Williamson, is the discussion of a scheme for placing New York and Philadelphia, which are 85 miles apart, within 36 minutes of each other—in other words, trains are to be run by electric means at an average speed of 141¾ miles per hour. Of course, very special plant is needed for this. The cars are to have no less than 12 7-feet diameter wheels each. The axles would be 15 inches diameter. The details seem to be boldly worked out, and no doubt the general scheme is feasible enough. "Cost-Keeping Methods in Machine Shop and Foundry" may be studied with advantage by the clerical staffs of large engineering works. No magazine which pretends to be up to date can well avoid discussing Klondyke, and under the title of "Exploring and Exploiting a Gold Country," this new El Dorado is described by Mr. Albert Williams. From this we learn that gold mining is by no means the easy digging that many imagine. "Progress in the Perfection of the Rock Railway," by Mr. E. L. Corthell, gives a succinct account of the various mountain railways in existence, principally in Central Europe. "The District Distribution of Energy," by Mr. Chas. Emery, is an account of the steam supply to the public in New York, but no new developments are mentioned. "The Esthetic (*sic*) Treatment of Engineering Work," by H. Heathcote Statham, has already been criticised in the engineering Press. The author's ideas may be gathered from his opinion of the Tower Bridge:—"It is the most terrible and monstrous piece of sham ever erected." As our readers know, this bridge is really a steel cantilever and suspension structure clothed in a masonry garb. If, as Ruskin, Carlyle, and other teachers have it, truth is the basis of all art then, and we agree with Mr. Statham, his strictures are merited. The Forth Bridge, in its naked simplicity, is a noble thing. Clothe the central towers in masonry as was proposed so as to make it harmonise with its environment (to use the spurious art jargon), and it would be, as Carlyle would say, a sham. We are glad that Mr. Statham has entered his protest against this kind of thing—it is badly needed at present, when it is deemed necessary that the latest railway coaches on the London and North-Western Railway and Great Western Railway shall resemble as much as possible the obsolete mail coach of 50 years ago. A very different subject is "Ericsson's First Monitor and the Later Turret Ships," by Geo. L. Fowler. This is a readable and well-illustrated article, but the writer, with pardonable patriotism, makes the common mistake of attributing the invention of the turret to Ericsson, whereas it was that of Captain Cowper Cowles who practically demonstrated the advantages of the turret in the Crimean War of 1854, whereas Ericsson's "Monitor" did not appear till 10 years later.

CATALOGUES.

WE have received from the Pope Manufacturing Company, of Hartford, U.S.A., a handbook containing directions for the care and advantageous operation of their motor carriages. This contains many useful hints to those who own or operate any kind of electric automotor vehicle. The value of the work would be enhanced if it were accompanied by drawings showing the connections, &c.

AMONG the more successful designs of gas-engines the "Forward" occupies a deservedly high place both for excellence in construction and economy in consumption. Messrs. T. Barker and Co., of Birmingham, have sent us their catalogue, which gives full particulars of this motor, the indicator diagrams being specially interesting. We note the consumption is as low as 21·9 cubic feet per B.H.P.

M. Th. CAMBIER, of Lille-Saint-Maurice, a well-known manufacturer of automotor vehicles and launches, sends us his catalogue of motors, &c. He makes six distinct types of vehicles, ranging from the "Duc à two places" to the "Diligence à 18 places," all operated by horizontal petrol motors. The information given is, however, of a very general kind, and hardly sufficient to decide an intending purchaser.

JUDGING by the price list to hand of the Motor-Car Company, 15, Red Lion Square, W.C., there should be no difficulty in the public obtaining practically any type of motor-vehicle for which they may be in search. There appears to be every class of machine, new and second-hand, from £30 upwards, and the Company are also prepared to deal upon the "Hire System." No doubt the Company are endeavouring to fill the usual "long-felt want," and their example should speedily find a host of imitators.

THE names of Edison and Swan are inseparably connected with the practical introduction of electric lighting, and the "Ediswan" Company have taken advantage of the present Jubilee year to issue a special catalogue, which includes a well written "Historical Review of the Introduction of the Electric Light into England," prefaced by an "Historical Review of the Company." There is also an interesting chapter upon incandescent lamps and their use. The Ediswan Company claim to be the only one which manufactures a lamp right through. From the prices given we should say that good incandescent lamps are now within everyone's reach.

WE have received from Messrs. Measures Brothers, the well-known iron and steel merchants of Southwark, a large sheet containing full-sized sections and dimensions of angle, tee-iron, channel, and other bars; also a handsome little pocket book, forming a useful catalogue of iron and steel work in general. Steel is now largely employed in situations in which a few years ago it was unknown; for instance, in building construction, steel girders and cast-iron columns have entirely replaced masonry and timber. Similarly, for railway carriages, trucks, and carriage work generally, steel is replacing timber. For motor-wagons it seems to us a *sine quâ non* to use steel channels or angles for the frames.

THE Electrical Power Storage Company's latest catalogue is of special interest just now, having regard to the large use of secondary batteries for motor-vehicle propulsion. This Company has succeeded in producing a cell which, so far, has given every satisfaction for this purpose. This cell is, we learn, the joint production of M. Faure, the original inventor of the secondary cell, and Mr. F. King, the Company's manager. It is fully described in the catalogue, as are the other cells made by the Company. The business in secondary batteries is really a very large one. Central stations can hardly be said to be properly equipped without a large amount of current stored in cells. And now that electric vehicles are becoming common, the E.P.S. Company will, we are sure, have a prosperous career. This catalogue is excellently got up, and printed on very superior paper.

MESSRS. ROBEY AND Co., of Lincoln, made a reputation very many years ago as manufacturers of high-class motors, and have steadily increased this by keeping well abreast of every modern improvement. In their latest catalogue, which by the way is a fairly thick, well printed, and copiously illustrated book of 150 pages, is an interesting account of their vast works. We note that Messrs. Robey make everything about their engines except the iron ore, and no doubt they would make this if they could, and so be quite independent. As regards their various types of motors, these are so well known and appreciated both by farmers and central station engineers—to mention two extreme classes of customers—that it is not necessary to say anything of them. We note that Messr.s Robey do not manufacture traction engines, and that they rate their boilers by nominal horse-power—a vague and meaningless term. On the other hand, the principal point of excellence about this catalogue is that dimensions, weights, &c., are given not only in British units but also in metric units, a great convenience to the foreign buyer. Manufacturers would do well to imitate Messrs. Robey in this respect.

EXPLOSION OF A TRACTION ENGINE.

THE following is an excerpt from the official report of an inquiry held under the Boiler Explosions Acts, as to the cause of an explosion of the boiler of a traction engine that occurred on June 14th, while the engine was going from Netherton to Halesowen.

The engine was owned by Messrs. H. and T. Danks and Co. (Limited), Crown Boiler Works, Netherton.

The engine driver, William Thomas, was scalded.

The boiler is of the locomotive type, and forms part of a traction engine. It is made of mild steel, with the following exceptions:—Fire-hole ring, foundation ring, and internal stays, which are made of wrought iron.

The cylindrical portion of the shell is 2 feet 6¾ inches in diameter and 5 feet 5¼ inches long; the shell plates are ⅜ inch thick, the longitudinal joints being double riveted and the circumferential seams single riveted. The rivets are ⅝ inch diameter and 1⅞ inches pitch. The mean length of the outer shell of the firebox is about 3 feet 4½ inches by 2 feet 8½ inches mean width, and its height about 4 feet ¾ inch; the back, front, and top plates are ⅜ inch thick, and the sides are ½ inch thick. The firebox is about 2 feet 11 inches long by 2 feet 3 inches mean width, and it is about 3 feet in height. The crown, front, and side plates are about ⅜ inch thick, and the sides are supported from the shell by 42 screwed and riveted stays, ⅞ inch diameter, made of Yorkshire iron, and pitched 4 inches by 4½ inches apart. The crown plate is supported by 35 stays about ⅞ inch diameter, which are screwed into the plate and fitted with nuts. The ends of the boiler are supported in the steam space by longitudinal stays attached to tee-iron brackets. The tube plates are $\frac{9}{16}$ inch thick; the one at the smoke-box end of the boiler is flanged to meet the shell, the other is also flanged and forms the back plate of the firebox; 41 tubes, 2 inches diameter and 12 B.W.G. thick, made of wrought iron, are fitted. The barrel is connected to the firebox "throat plate" by a single riveted joint. The mountings of the boiler consist of:—One pressure gauge, one glass water gauge, two test cocks, three blow-off cocks, four mud doors, one manhole door, two feed check valves, one filling plug, one fusible plug, two safety valves, 1½ inches diameter, loaded by springs to 140 lbs. per square inch.

The traction engine was built in 1892 by Messrs. John Fowler and Co., Leeds. No big repairs have been necessary, but a new internal feed pipe was fitted about six months previous to the explosion. The boiler was not insured; it was inspected periodically by Mr. Joseph Jewkes, foreman fitter to the owners of the engine, Messrs. H. and T. Danks and Co , and the last inspection was made on the 1st July, 1897.

The cause of the explosion was that the thread on the feed pipe gave way, and the check valve was blown off, steam and water escaping with great force through the orifice, and this was brought about by the defective condition of the thread upon the feed pipo.

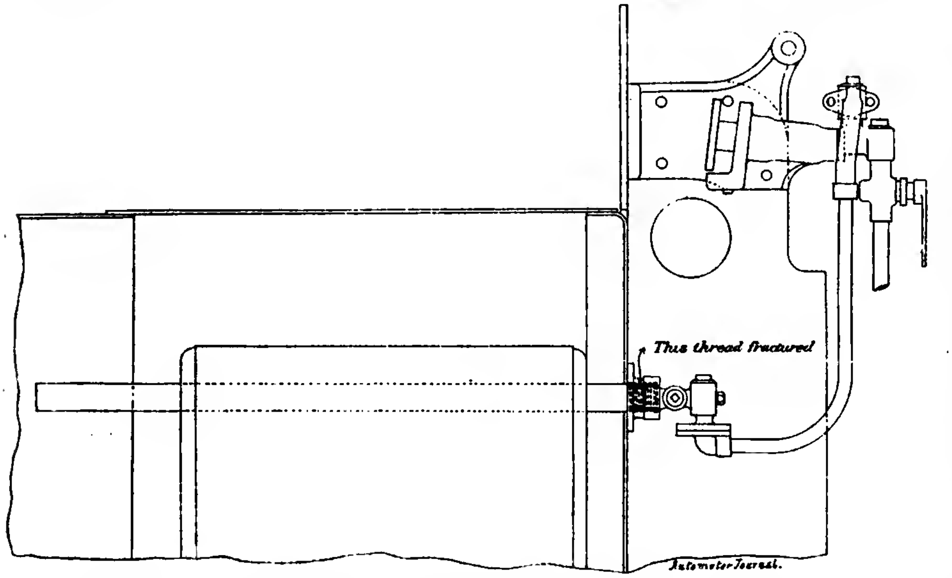
General Remarks.

The pipe which gave way was fitted to the boiler six months previous to the explosion on account of the internal part of the old pipe being split, the screwed part, it is said, being in good condition; the new pipe was made of iron, and was 2⅜ inches outside diameter, and $\frac{3}{16}$ inch thick, screwed at one end for a length of 2¼ inches, with 11 threads to the inch; this end is screwed through an iron plate riveted to the boiler front, and projects 1 inch; to this projecting part the check valve is screwed, and a joint is made between the nut on the valve chest and the plate on the boiler front; the remainder of the pipe, 3 feet 6 inches long, acts as an internal feed pipe.

The rough work that these engines do, and the vibration set up by their passage over bad roads, necessitates the constant overhauling of the machinery. Messrs. H. and T. Danks and Co. give instructions to their drivers that in case of any repairs becoming necessary, a report is at once to be made to the foreman fitter, who is responsible for doing what is required.

Observations of the Engineer Surveyor-in-Chief.

This explosion appears to have been caused by the failure of the thread of the feed pipe to which the check valve was attached. The joint of the valve was reported to be leaking, and was remade on the morning of the explosion, when the thread in question was observed to be defective, and it is said to have been arranged that a new pipe should be fitted, although no immediate danger was apprehended. The thread on the pipe appears, however, to have been in a worse condition than was thought, and its holding power proved to be insufficient to resist the vibration caused by the engine passing over rough roads.



Unfortunately one man was injured, and the case furnishes another illustration of the importance of insuring that the means by which all such fittings are attached to a boiler are in good condition.

THE electric tramway system of Montreal comprises 75 miles of track, traversed by from 170 to 200 motor-cars per diem; these cars run about 7,000,000 car-miles per annum, and carry in round numbers 30,000,000 passengers. The speed at which they travel through the streets is 7½ miles an hour, and the service is kept up, according to the requirements of the town, from 5 a.m. until 2 o'clock the next morning. The averages of some three years' operations of the power station are appended :—

Coal consumed per car-mile	7 lbs.
Coal consumed per ton-mile	1 lb.
Coal consumed per electrical horse-power	2·75 lbs.
Power consumed per motor-car mile	2,000 watt-hours.
Power consumed per ton-mile	293 "
Resistance to haulage per ton (draw-bar pull)	147 lbs.

CORRESPONDENCE.

THE ENFIELD STEAM CARRIAGE.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

DEAR SIR,—I have had great pleasure in reading your very able report upon the heavy self-propelled vehicles in France. It proves one thing: that an omnibus of four tons tare, carrying 20 persons, can be propelled 14·7 miles at the cost of 8*d.* for fuel, and if we say water and oil at one halfpenny, total 8½*d.*; it is therefore a little over one halfpenny per mile. The tanks hold 100 gallons, which would be sufficient for a journey of 23 miles.

Please compare the above with the vaunted economy of the spirit motor. Coventry Bollée, weight 3¼ cwt., carrying two persons and a portmanteau, cost per mile said to be one halfpenny; Sterling motor, carrying three persons and 100 lbs. of baggage 100 miles, 4*s.* 7*d.*, which is over one halfpenny per mile.

I wish to bring to your notice the splendid performance of the Enfield Steam Carriage which ran in the year 1849. Number of passengers on carriage, 50; average speed, 37 miles per hour; average consumption of coke per mile, 11·48 lbs., or under 1*d.* per mile. We must not forget our worthy friends, Messrs. Merryweather and Shand and Mason, who, I think, in the year 1862 stood a very severe trial at the Crystal Palace with their fire engines, 100 lbs. pressure of steam from cold water in 10 minutes 25 seconds in the one case, and 10 minutes 51 seconds in the other.

What a lot we have learned since the above periods when we are obliged to fit our warships with a French boiler.

That the De Dion and Bouton omnibus gave every satisfaction is a great credit to the designers, but to me there are some very grave errors in the construction, both in the vehicle and the boiler.—Yours faithfully,

HENRY SPORTON.

Enfield.

[Our correspondent must not forget that the more important advances in engineering science during the last 30 years have with few exceptions been of French or German origin. French boilers, viz., the "Belleville," Du Temple, Niclausse, and others are fitted in British warships simply because of their practical advantages. The De Dion boiler is in our opinion one of the most suitable boilers for road locomotion, as it provides the maximum of heating surface with the minimum of weight.—ED.]

A WORD FOR ELECTRICITY.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Though it is not to be doubted that for heavy, long-distance traffic on common roads, steam-power will eventually be employed in some form or other, it must be admitted that for lighter work it is totally unsuitable. For steam machinery, with its numerous complications, skilled attendance is a necessity, and two responsible officials will always be required on a steam vehicle: one to drive and the other to attend to the boiler and engines; and for a small private vehicle this is quite out of the question. Where steam fails, however, there electricity may perhaps step in. Storage batteries are terribly heavy, no doubt, and not suitable for extended journeys into remote wilds (at least, not at present), but against this manifest weakness on their part may be set the following theoretical advantages that are perhaps not impossible of practical attainment :—

1. The employment of wind and water power in country districts to charge cells automatically — a most important economy not involving great outlay.

2. The possibility of converting the motor into a dynamo while descending hills (instead of using a brake) and charging the cells, thus regaining some of the energy expended before in going *up* hill.

Then of course there are the admitted advantages of non-vibration, cleanness, absence of noisome products, and ease of manipulation. If, as suggested before, we suppose *three* pairs of wheels to be provided, we obtain double battery space with the same steering facility as in shorter vehicles, and the weight of the cells disposed symmetrically on both sides of the central driving axle. There is no reason, surely, why we should not make our "horseless" vehicles quite as long as the horse and cart which now dominate our roads.—I am, &c., A. J. A.

November 3rd.

[There is no reason why three pairs of wheels should not be employed. We have always maintained that the effective length of a horse-drawn vehicle is the distance between the nose of the beast and the tail board, and motor-vehicles should be at least as long as this.—Ed.]

MOTOR-CARS AND THE LORD MAYOR'S SHOW.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—My directors will feel obliged by your inserting the following correspondence, which has taken place between us and the Lord Mayor and Sheriffs Company. My directors naturally feel they have been treated unfairly.—Yours faithfully,

The Elieson Lamina Accumulator Co. (Ltd.).
W. S. Naylor, Secretary.

4, Greenland Place, Camden Town, N.W.,
November 8th, 1897.

Lord Mayor and Sheriffs Committee, Guildhall, E.C.,
October 21st, 1897.

Dear Sir,

I am desired by Mr. Pannell to thank you very much for your letter and the photograph, and to inform you that upon full consideration the Committee do not see their way on the present occasion to include a motor-car of any description in the procession.

Yours faithfully,

W. S. Naylor, Esq., J. W. Sandy, Asst. Secretary.
Elieson Lamina Accumulator Co. (Ltd.).

On November 5th a printed circular to the following effect was received :—

Lord Mayor and Sheriffs Committee, Guildhall, E.C.,
November 4th, 1897.

Dear Sir,

I herewith enclose the Police instructions as to the time and place for your electric carriage to join the procession. Be kind enough to acknowledge the receipt, in order that I may be assured that all arrangements are completed, so far as you are concerned.

Yours faithfully,
J. W. Sandy, Asst. Secretary.

The previous circular was acknowledged on the 5th instant, and the following letter was received on the 6th instant :—

Lord Mayor and Sheriffs Committee, Guildhall, E.C.,
November 5th, 1897.

Dear Sir,

A letter intended for someone else was posted to you last night in error. The letter contained a direction for an electric carriage to be in Coleman Street, on Tuesday next, to take part in the procession.

Please to understand that this letter was intended for someone other than yourself, and that, as you have been already informed, the Committee cannot use your motor-car on this occasion.

Yours faithfully,

The Secretary, Wm. H. Pannell, Hon. Sec.
Elieson's Patent Electric Motor-Car Co.

THE BERLIN FIRE BRIGADE STEAM TRICYCLES.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—In your October, 1897, issue, you say, on p. 15, that in Berlin the fire brigade employs steam tricycles. Will you be good enough to get us particulars of these to carry one and two persons, along with best cash prices to trade and illustrations, as we are open to buy if satisfactory, and take up agency to sell? Your kind attention will be much esteemed and oblige.

Harrison and Co.

Pocklington, *October 29th*, 1897.

[We would suggest to our correspondents that they write to the Berlin Municipal Authorities, and to the British Embassy, at Berlin. In both cases they will, we are sure, be given every information. They might also place themselves in communication with the nearest German Consul. Or again, they might communicate through their local Chamber of Commerce, or through the London Chamber of Commerce. We ourselves can hardly be expected to act as commercial agents for individual firms.—Ed.]

LOAN OF LECTURE SLIDES.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Will you allow me to say that I shall be happy to lend my series of lantern slides of motor-carriages to any responsible individual for lecture purposes.

There is so much ignorance in some localities as regards this new means of locomotion that I hope lectures on the subject may be of some use.

My slides now number about 60, some unfortunately are rather thick, so a good light is necessary. John Henry Knight.

[We have much pleasure in giving publicity to our correspondent's offer, and quite agree that lectures such as he himself gave recently at the Camera Club would be of distinct educational value in the country districts.—Ed.]

DESIGN OF STEAM MOTOR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir.—As a constant reader of your interesting paper, I should be pleased to hear if you could help me with a steam motor-car I am having built here.

1. Can you give me address of maker of oil (paraffin) burners?

2. Is there any suitable condenser made for steam cars, and who should I apply to for design?

3. The car I am building is to have four wheels—ought the power be applied to the front or the back pair? which would give the most hill-climbing power?

Any information you can give me will be gratefully received.—Yours truly, Louis Knoblauch.

Leith, *November 2nd*, 1897.

[(1) and (2). Apply Liquid Fuel Engineering Company, Cowes, Isle of Wight; also to Thorneycroft's, Chiswick. (3) The power should be applied to the after-wheels.—Ed.]

WANTS AUTOMOTOR VEHICLES.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir.—I am badly wanting to find the very best motor carriages for a foreign country, to carry two, three, or more tons slowly. Also light motor-cars and tricycles of the very best kind. I have heard of a foreign motor tricycle, said to be perfect, and of which there are some half-dozen in England, or coming, but I cannot trace them.

If you can help me by advising me where to apply please do so, or by sending me any copy or copies—back numbers of Journal—which give the requisite information, please send them, and I will send the money for them by return of post.—Yours faithfully,

Bexley, *November 2nd*, 1897. F. I. Cooke.

[We could not advise as to the "best" or "very best" motor vehicle. Most of the better-known makes of motor vehicles advertise in our columns, or, if our correspondent can wait till our Diary for 1898 is issued, he will find therein a very complete directory of makers, &c. Copies have been sent as requested.—Ed.]

THE VALUE OF ADVERTISEMENTS IN "THE AUTOMOTOR JOURNAL."

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—Please continue my advertisement this month and until further notice.

I am pleased to inform you I have received 165 answers up to now from the last advertisement, some of them from important business people whom I had previously no idea were in any way interested in motor-cars.

Wishing your much-appreciated journal continued success, I remain, yours sincerely, F. Frentzel.

November 10th, 1897.

FLASHING BOILERS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I duly received No. 1, Vol. II, of the Automotor, &c., Journal, and sent P.O. and stamps (6*s.* 6*d.*) in payment of the remaining numbers, and 7*d.* for a copy of the "A. and H. V. Handbook."

Can you give me any information about flash boilers?—Yours truly, Alex. Douglas.

Stranraer Foundry, Stranraer, N.B.

[The flash boiler, which is an old English invention dating from 1736, depends upon the principle of supplying a large excess of sensible heat to a very small quantity of water enclosed in a very strong chamber whereby the evaporation is instantaneous. In practice very thick tubes, ·39-inch to ·45-inch thick, are flattened or curved to a U section till the internal space is about ·125 inch in width. The tube is heated to about 800° to 900° C. (a red heat). Water is injected into the thin lamina-like space, and is instantaneously converted or flashed into steam. The pressure depends upon the heat supplied directly, and upon the quantity of water injected inversely. The best-known form of flash boiler is the Serpollet. This system has often been described in the technical journals, and a good account of it will be found in "Farman's Auto-Cars" (Whittaker and Co.). We shall in a near issue describe the Serpollet tramway system as used in Paris.—Ed.]

A VARIABLE SPEED GEAR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—If I can produce a variable ratio and reversing gearing capable of reversing or varying the ratio from maximum to minimum in either direction from a motor running constantly in one direction, are you open, or can you tell me of anyone who would be, to negotiate for the patent rights in the same?

The variation is positive, and is not affected by the uncertain slip of a brake (although adaptable to that).

The whole of the operations of starting, stopping, reversing, or varying the ratio are controlled by one handle.

The gearing may be adapted to serve as anti-friction bearings for the shaft or wheel to which it is applied; and it is almost impossible for the motor to stop through being overloaded, as in one form the ratio is altered by the load itself when too great. There is scarcely any loss by friction in the gearing; I should say about as much in the entire gear as there is in a ball bearing.

It may be used either as tooth or friction gearing, or both. It will transmit a good power as friction gearing, because of the large number of contact points we are able to provide by this arrangement.

An exhaustive search has not found any anticipation.

Several cycle makers and engineers who have seen it pronounce it to be just what is wanted, and are negotiating for licences at varying royalties, but I want to get an influential gentleman who could put the thing on the market properly to take it up before accepting their offers of 5*s.* per gear.

The chief objection to all friction gears has been that the whole of the power has to be transmitted through one, or at most two, points of contact. I can use 20 or 30, or more.

Another fault is, so much pressure must be put on the bearings to give sufficient grip that the metal crushes, and also a lot of power is lost through friction in the bearings, due to the excessive pressure. Mine has none of these objections.—Yours respectfully,

5, Strand, Southampton. W. Woolidge.

[A good variable speed gear has undoubtedly a large field for employment. We could not take steps to negotiate any business matter, but no doubt the publication of your letter will cause some of those interested to communicate with you.—Ed.]

THE DURYEA MOTOR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Can you tell your readers what has become of the Duryea motor-car? After seeing the excellent running of these American cars on the trip to Brighton last year, one is surprised not to see them more in evidence here.

A report has been whispered that the inventor was bribed by another firm or rival company to take his ingenious vehicle back to the States. Perhaps you can tell me if there is any truth in the report. I enclose my card. N. Y. T.

November 2nd.

[We have no knowledge of the "bribery" mentioned by our correspondent. The Duryea motor-car was temporarily in the hands of Mr. McKim, of Cannon Street, who was adjudicated bankrupt some little time back, since which this car seems to have dropped quietly away. We believe, however, that a personal representative of the Duryea Company has for some months past been in England in connection with introducing the car to the British public, and no doubt he has carried on active negotiations with various people to that end, the result of which we shall probably see presently.—Ed.]

THE AUTOMOBILE CLUB OF FRANCE AND THE SELF-PROPELLED TRAFFIC ASSOCIATION.

The following letter has been received from Mr. Andrew W. Barr, the Secretary of the Self-Propelled Traffic Association, and we have very much pleasure in giving it publicity in our columns:—

To Sir David Salomons, Bart., *President of the Self-Propelled Traffic Association.*

November 4th, 1897.

Dear Sir,—I have the pleasure to inform you that at a meeting held yesterday, the Committee have finally appointed the Self-Propelled Traffic Association to represent the Automobile Club de France in Great Britain.

This step has been taken both as an acknowledgment of the interest of which you have given us so many proofs, and as a mark of sympathy with the Association over which you preside, and whose members include so many distinguished elements with whom we are happy to be identified.

As a result of this decision the members of your club when staying in Paris may, upon the written request of the President of the Self-Propelled Traffic Association, have extended to them for the time being all the advantages enjoyed by our colleagues of the Automobile Club of France.

Such members will receive for the purpose a personal card of invitation, signed either by myself or by a member of the Council of Administration.

Yours, &c.,

Baron de Zuylen de Nyevelt.

PROCEEDINGS OF TECHNICAL SOCIETIES.

Mechanical Propulsion on Canals.*—(*continued.*)

It is important to know how the resistance of the same boat, loaded to the same draught, alters in passing from a canal of one section to a canal of another. Some experiments upon this point were made in 1894, of which the following is a brief account. It may be premised that the ratio $n = \frac{\Omega}{\omega}$, which the wetted section Ω of the canal bears to the immersed midship section ω of the boat, obviously cannot sink below unity; and also that, the more nearly the ideal conditions of smooth water are approached, the more nearly does the ratio $n = \frac{\Omega}{\omega}$ approach infinity. As a limit, therefore, it may roughly be said in a general way that, when $n = \frac{\Omega}{\omega} = 1$, $\frac{R}{r} = \infty$; and when $n = \frac{\Omega}{\omega} = \infty$, $\frac{R}{r} = 1$. In Table 7 is given the values of the ratio of sections $n = \frac{\Omega}{\omega}$ and of the ratio of resistances $\frac{R}{r}$, obtained from experiments made with the "Jeanne," a boat of the "Flûte" class, 99 feet long and 16·44 feet wide, towed in the River Seine and in four different canals, with draughts of 3·28 and 4·27 and 5·25 feet, and at speeds of 0·82 to 4·10 feet per second or 0·56 to 2·80 miles per hour. In the River Seine, where the minimum value of the ratio $n = \frac{\Omega}{\omega}$ was not less than 72·5, the ratio $\frac{R}{r}$ which the resistance R in a canal bears to the resistance r in a river, can without appreciable error be taken as 1·00. From Table 7 it will be seen that, with a draught of 4·27 feet and at a speed of 2·46 feet per second or 1·68 mile per hour, the ratio $\frac{R}{r}$ of the resistances of the "Jeanne" is only 1·38 in the Dérivation de Joigny, where the ratio n of sections attains a value of 6·39; while in the Canal du Nivernais, where the ratio n of sections falls to 2·04, the ratio $\frac{R}{r}$ of resistances rises to 3·82: that is, for a reduction to a little less than half in the ratio of the sections, the ratio of the resistances is nearly tripled. This example shows how great an influence the ratio of the sections has upon the resistance. The figures given in Table 7 are purely experimental, and not arrived at by any mathematical calculation. At the speed of 0·82 feet per second it will be noticed that the resistances in the River Seine are the same at draughts of 3·28 and 4·27 feet; this is probably due to the fact that the resistances were measured to the nearest kilogramme, and therefore a difference of less than 2 lbs. would not be noticed in converting the readings from French into English measure.

Formulæ.—The foregoing results obtained by M. de Mas afford a means of checking the formulæ usually adopted for the resistance of boats to traction upon canals. The two following are believed by the author to be the formulæ most generally employed, in which $n = \frac{\Omega}{\omega}$:—

$$R = K\omega V^2 \frac{1}{n+2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

$$R = K\omega V^2 \left(\frac{n}{n-1}\right)^2 \quad . \quad . \quad . \quad . \quad . \quad (2)$$

The first formula was propounded by Du Buat in the last century, and has been applied by D'Aubuisson to the resistance of boats upon the Midi Canal. The second is deduced from the formula used for an open expanse of water—namely, $R = K\omega V^2$—by substituting for the absolute speed of the boat in open water its relative speed in relation to the water flowing backwards past it, on the assumption that the water would pass back from bow to stern at a uniform speed through the narrowed section $\Omega - \omega$. From the results now obtained by M. de Mas are deduced the three following conclusions:—First, for a boat hauled at a given speed, V, the resistance to traction is not proportional either to $\frac{\omega}{n+2}$ or to $\frac{\omega\, n^2}{(n-1)^2}$; second, for a boat kept at a constant draught the resistance to traction is not proportional to V^2; and, third, for a given boat the proportions $\frac{R\,(n+2)}{\omega\, V^2}$ and $\frac{R\,(n-1)^2}{\omega\, V^2\, n^2}$ are neither of them independent of the speed. Hence it will be seen that the two above formulæ can give only wrong results. Recently M. de Mas has been engaged on experiments with a view to determine the variation of resistance offered to a boat when the area of cross-section of a canal is kept the same, while its width and depth are altered; his results, however, have not yet appeared.

TABLE 7.—*Ratios of Sections* $\frac{\Omega}{\omega}$ *and of Resistances* $\frac{R}{r}$ *of boat "Jeanne" in different Waterways.*

R = resistance to traction in canal; r = resistance to traction in river.

Draught.	Waterway.	$\frac{\Omega}{\omega}$	0·82 ft. per sec.			1·64 ft. per sec.			2·46 ft. per sec.			3·28 ft. per sec.			4·10 ft. per sec.		
			R	r	$\frac{R}{r}$	R	r	$\frac{R}{r}$	R	r	$\frac{R}{r}$	R	r	$\frac{R}{r}$	R	r	$\frac{R}{r}$

It has been found over and over again that, as the depth of a canal is augmented, the ease with which a boat can be towed is increased. In the discussion upon the late Mr. F. R. Conder's paper upon "Speed on Canals" ("Proceedings Inst. C.E.," 1884, vol. lxxvi, p. 160), it was stated by Mr. Robert Gordon (p. 198) that within the limits of his experience retardation of speed and deficient steering power "were much more strikingly developed in shoal water, with only a few feet between the bottom of the vessel and the bed of the canal, whatever the breadth of the stream might be, than in a restricted narrower section of greater depth." On the Forth and Clyde Canal, on which there is steam navigation, and where,

* Abstract of paper read by Mr. LESLIE ROBINSON at the Institution of Mechanical Engineers.

according to Sir Arthur Cotton, the ratio of wetted section Ω of canal to immersed cross-section ω of boat amounts to 3 : 1, it is found that a higher speed than five miles per hour cannot be adopted, because above this speed the water is not delivered quickly enough at the stern to admit of effective steering. In the discussion upon Messrs. Clegram and Healy's papers in 1866 ("Proceedings Inst. C.E.," 1866, vol. xxvi, p. 1) the two following conclusions were drawn by Mr. William Beardmore (p. 43):—"Firstly, that with any flat-bottomed vessel propelled by a screw, immersed to its full diameter in a canal where the sectional area of the vessel was less than one-seventh part of that of the whole waterway, the speed was sensibly affected (independently of the laws of motion of bodies through narrow canals) wherever the depth below the vessel's bottom did not exceed two-thirds of the diameter of the screw. Secondly, that when the sectional area and depth of canal were less than the above proportions, the velocity at which the screw could be worked with advantage was limited by the speed with which the water could pass beneath the boat so as to feed the screw. In other words, if a speed were obtained beyond that at which the water would pass to the screw, the engine power was wasted in churning the bottom water."

Speed.—The speed attainable upon a canal must necessarily be limited by the consideration of the preservation of the banks. Up to a speed of three miles per hour it was found by Dr. Pole that no waves were formed which had an injurious effect on the sides of the canal; but above that speed breaking waves became developed, and had a most destructive effect upon the banks. At moderate speeds it has been found that the wasting of the banks extends only about 1 foot above and below the water level. The difficulty of preserving the banks was one of the great hindrances to the use of steam power upon canals. When it was first determined about 1860 to try towing by steam upon the Ashby-de-la-Zouch Canal, the railway owning the canal objected; and the matter was referred to Dr. Pole, who tried a boat propelled by a screw at different speeds, with the result already mentioned, namely, that no damage was done up to three miles per hour, but that above this speed breaking waves were formed. The highest speed allowed in France is from six to eight kilometres, or about 3¾ to 5 miles per hour, while in England three miles per hour is the usual speed. In narrow canals, and in tunnels such as that on the Canal de Saint-Quentin, the speed has to be further reduced, owing to the heaping up of the water in front of the boat. An instance is cited by Lermoyez in 1863, in which the last of a train of barges was left on a dry keel, owing to the water not being able to flow backwards past the boats quickly enough to supply the void caused by their passage. They acted indeed like the plunger of a pump, forcing the water before them: and the only way in which they could be moved along was by waiting for intervals of 20 minutes until the water had returned to its normal level in the canal. Even in a moderately wide canal, by keeping the traffic moving continuously in the same direction over a distance of 30 miles for a whole day, Scott Russell found the water raised 18 inches higher at one end of the canal and lowered 18 inches at the other, making a total difference of level of three feet.

With regard to altering the shape of the boat in order to gain increased ease of traction, the experiments of M. de Mas may be again referred to. He has experimented with two builds of boat already mentioned, which are known locally as a "Péniche" and a "Toue" (ferry-boat), having the same length of water line and the same width amidships. The "Péniche" is but slightly rounded at each end, and the bottom is only slightly cut away at the stem and the stern; the boat is therefore full-bodied, the coefficient of fineness being 99 per cent., that is, the ratio which the volume of the displacement bears to the parallelopiped circumscribing the immersed hull is 99 per cent. The "Toue" is square at the stern, but rather more cut away at the bow than the "Péniche," and its coefficient of fineness is consequently reduced to 97 per cent. Both these builds of boat have flat bottom and parallel sides. With a draught of 4·27 feet and at a speed of 1·68 miles per hour the resistance of the "Toue" is 232 lbs. less than of the "Péniche," while with a draught of 5·25 feet and at the same speed the decrease is 366 lbs. The loss of carrying capacity in the "Toue" consequent on the difference in shape, is 5·9 tons; so that for this small reduction in carrying capacity there is a considerable diminution of resistance to traction, and a consequent increase in speed might be obtained. The resistance of boats to traction is also increased in going round curves; and M. Flamant ("Annales des Ponts et Chaussées," 1881, vol. i, p. 214) has shown that the power required to tow a boat round a curve of 328 feet radius is just double that required on a straight stretch of canal having the same cross section as the curve. French canals, however, are usually made of extra width in curves; and it is then found that a curve of 328 feet radius does not materially increase the resistance to traction on a canal intended to carry boats of 125 to 128 feet length and 16½ feet width.

Mechanical Propulsion.—There are four different methods in use for the mechanical traction or propulsion of boats upon canals, which will be taken in the following order:—(1) propulsion by screws worked either by steam, by petroleum motors, or by electricity; (2) hauling upon a submerged chain or wire rope lying along the bed of the canal; (3) attachment to an endless running rope working along the canal bank; (4) towing by a locomotive running along the canal path. These the author believes are the only plans at present in use on canals, or passing through the experimental stage. Upon the Continent a few stern-wheel steamers are in existence on rivers; but they are seldom used on canals, because they occupy so much room in the locks, and the stern wheel takes up a good deal of valuable space that might be occupied by cargo.

(To be continued.)

Some Points in Cycle Construction.*

THE rapid development of the modern bicycle is mainly if not entirely due to the influence of the racing track in securing the extinction of the least fit. The advance has been made by a lengthy and expensive process of trial and error; but this process would have been far more tedious and expensive, if it had been left to the judgment of the average rider to decide what constituted fitness. It is in the final struggle at the end of a well-contested race that the fine shades of difference in the speed of machines have been discriminated. This method of experiment may eventually give place to others more scientific and more exact; but the latter are hardly likely to be so popular. It is now generally understood that the property of speed, possessed in such various degrees by cyles, is mainly a negative property; that is, it is the absence of any means of dissipating the energy transmitted through the mechanism; in fine, the whole question is one of efficiency. The best machine both for racing and for ordinary riding is that which is most efficient. The principal causes of inefficiency in a cycle are—want of rigidity, and friction:—A cycle which should be absolutely rigid and entirely without friction would have an efficiency of 100 per cent.; that is to say, it represents an ideal perfection which cannot be exceeded, and cannot actually be attained.

Rigidity.—Of these two sources of inefficiency, it is probable that want of rigidity is the most important. It is in this particular that cycles differ far more than in friction; and it is invariably found that the more rigid machine is also the faster. The cause is twofold. Firstly, the work done in springing the frame out of shape at each stroke of the foot is not spent in driving at the end of the downstroke, but only in lifting the foot at the beginning of the upstroke. The amount of exertion wasted in this way may be fairly estimated by sitting on a machine with the wheels fixed, and alternately applying and relieving the pressure of the foot on the pedal; the more springy the machine, the greater will be the fatigue experienced. Secondly, the springing of the frame causes a general condition of instability, due partly to the alteration of the balance through lateral movement of the pedals, and partly to the wheels being forced out of line, thereby causing the machine to swerve from side to side, instead of running a true course. Although the loss of efficiency from this cause may seem slight, the sense of instability has a disastrous effect in marring a sudden effort or in aggravating a steep hill.

Friction.—In a machine with well-constructed bearings, friction is mainly due to the chain. The consequent loss has been variously estimated, as low as 1 per cent. of the total power has been recently given. If this were correct, chain driving would be the most efficient means of transmitting power at present known. Probably, however, the loss was measured when the chain was not doing any work, which would make the test fallacious. About 5 per cent. seems nearer the truth. The means of avoiding these various sources of inefficiency may be considered in detail; and at the same time the means by which the ordinary stresses in a vertical plane may be met with the minimum of material.

Factor of Safety.—It has been said that the factor of safety for a cycle frame is about 1¼. If this is understood to mean that a machine designed for a 12-stone rider should not be ridden by one exceeding 15 stone, it is probably not far out in most cases; yet

* Paper read by Mr. F. J. Osmond, of Birmingham, at the Institution of Mechanical Engineers.

a well-built frame will carry a steady load of at least 10 times this weight without injury. The difference between these two statements is due to the fact that the front part of the frame is exposed to shocks which must cause bending stresses near the head; for if the two front tubes are arranged so that their axes intersect vertically above the axle of the front wheel, the stresses are only pure tension and compression, so long as the force acting through the front axle is purely vertical. It is evident that this is not the case when the front wheel meets a brick or other obstacle which represents a force acting obliquely; whilst when the wheel drops on the other side of the obstacle there is a shock which is vertical. It is thus impossible to avoid bending; and the best compromise is obtained by making the axes of the two tubes meet some distance behind the perpendicular through the front axle. This consideration is sufficient to justify the present shape of frame with short head and horizontal top-tube. Any considerable obstacle surmounted by the front wheel causes two distinct shocks, the first oblique and the second vertical; and these shocks will in general tend to bend the front tubes first in one direction and then in the other. The bending moments are greatest close to the head, just where the tubes have been weakened by brazing; it is, therefore, necessary to provide some local strengthening. This, the author gives by shrinking a reinforcement about 4 inches long upon the outside of the tube ends; the tubes are brazed together at the ends, tapered in a lathe, and the whole then brazed into the lug. By this means the part weakened by the brazing is kept within the reinforcement, and breakage is practically impossible.

Large Tubes.—Although there is an evident advantage in increasing the diameter of tubes subjected to bending and tension, yet, as the thickness must be reduced in order to retain the same weight, a limiting ratio of diameter to thickness is soon reached, which cannot be exceeded without danger of the tube failing through buckling induced by some small local stress due to dents, &c. This ratio is much smaller when the tubes are curved, as in handle-bars, which, if made of too thin metal, will fail at the bend, and not at the junction with the stem, where they ought to fail first if their strength is calculated from the bending moment only. In multicycles, where heavier tubes are necessary, the diameters may be considerably increased with great advantage to the general strength and rigidity. For tandem and triplet cycles the author makes tubes 25 per cent. larger in diameter than for single machines, which gives about 50 per cent. more rigidity for the same weight.

Aluminium Frames.—The advantages of aluminium and its alloys, as compared with steel, have been so often urged that a few facts may be interesting. The best aluminium alloys have about 16 per cent. less strength and rigidity when drawn into tube than a steel tube of the same weight and outside diameter; but owing to its much greater thickness the aluminium tube can be made of larger diameter without danger of buckling. For handle-bars aluminium has greater advantages, and if it could be readily plated, it would be really valuable for this purpose. The difficulty of jointing is much against it in most cases. For the comparison of strength and rigidity the tubes tested were both 1 inch outside diameter, and practically of the same weight per foot; the steel tube was 20 gauge or 0·036 inch thick, and the aluminium alloy 12 gauge or 0·110 inch thick. The superiority of the steel tube was due to its greater mean diameter; making allowance for this, the strengths and stiffnesses of the two materials are nearly equal. The maximum stress in the steel tube was 52 tons per square inch, and in the aluminium alloy 18·7 tons per square inch. The effect of a brazing heat was to reduce the strength of the steel by 45 per cent., thus bringing down its maximum stress to 28·6 tons per square inch; the stiffness was unaffected.

Testing of Tubes.—In testing tubes it is necessary to take special precautions in order to avoid buckling by local stress. For example, if the tube is supported at the ends and loaded at the centre, it should be of considerable length, say 3 feet for 1 inch diameter, and the load should be suspended by a broad leather strap, so as to distribute the pressure over a large surface. Through the neglect of these precautions the results of many published tests have been rendered entirely misleading. The advantages so often claimed for "webbed" tubes are apparent only when the tube is tested in short lengths and loaded in the centre. Under these conditions a plain tube is crushed in at the point where the load is applied, which is also the point of maximum compression stress due to the bending. It therefore fails prematurely from a local stress, which has no counterpart in the working stresses of a cycle. When tested with proper precautions, webbed tubes are both weaker and less rigid, weight for weight, than plain tubes, a result which accords with theory. The same may be said of various other sections. It is in many cases better to test by brazing a solid plug into one end of the tube, and having clamped this end, to load the other end; in this way all unfair stress is avoided. Corrugated tubes have the advantage of resisting local stress better than plain tubes; but they are less rigid, weight for weight, and present difficulties in jointing. Nickel steel is as rigid as carbon steel, and has the advantage of a higher elastic limit; it is therefore well suited for the two front tubes of a cycle, which are the most subject to vibration. In other parts, where the elastic limit is not so nearly approached, it has no advantage over ordinary steel. It is a mistake to suppose that the mildest steel is the safest under vibration; owing to its low elastic limit it is more liable to break off short from vibration than harder steel containing up to 0·8 per cent. of carbon.

Means of Securing Rigidity.—In considering the design of a safety bicycle frame, too little attention is generally paid to what may be called the driving stresses; that is, those set up by the pressure of the foot upon the pedal, which causes lateral distortion of the frame. There are two distinct cases to be considered—first, when the pressure of the foot is balanced by a pull at the handle on the same side; and second, when there is no pull at the handle. In the first case, when the pressure of the foot is balanced by a pull at the handle on the same side, the distortion is confined mainly to the front part of the frame, consisting of the head tube, the upper and lower front tubes, and the seat-socket tube. Each member of this quadrilateral is subjected to both torsion and bending. If any one of these members is so strengthened that its bending and twisting are diminished, then the strength of the adjacent members is also increased, so that much greater forces are required to produce a given distortion. Now the head tube being short compared with the other members, an increase in its thickness is accompanied by an increase in the stiffness of the frame out of all proportion to the increase of weight. This stiffness is also increased up to a certain point by shortening the head tube. The long heads in vogue a few years ago rendered the frame more springy, while the present pattern of frame, with horizontal top tube and comparatively short head, is much better in this respect. The torsion of the seat-socket tube is greatly diminished if the rear part of the frame is rigidly connected, instead of being merely bolted together. When the torsion of the head tube and seat-socket tube is thus minimised, rigidity is secured by providing top and bottom front tubes of suitable diameter and thickness. In the second case, when the pressure of the foot is not balanced by a pull on the handle, the distortion is not confined to the front part of the frame, but every member is twisted and bent simultaneously. The rigidity thus depends mainly on the joints throughout the frame. In a machine wanting in rigidity, the wheels and the frame are no longer in the same plane; the wheel inclines to one side of the vertical and the frame to the other, and the direction of the inclination alters at each stroke of the foot. The stresses thus set up are much the same as if the wheels were fixed, and the frame twisted by means of the seat pillar. If the joints are made merely by flattening the ends of the tubes and then bolting up, the frame is liable to be rickety, because under bending and twisting stresses such joints will give more than the whole length of the tube. This source of weakness is avoided in the author's practice by brazing the back forks and chain stays together, without any flattening or weakening of section, and by reinforcing the joint with a wrapping of sheet steel. At the junction of the seat-socket tube the back forks are also brazed on, and the solid end-piece, after brazing in, is recessed to take the seat-pillar bolt. This connection is so rigid as to permit of dispensing with the usual bridge above the back wheel. In the same way the ends of the front fork are stiffened so as to increase the lateral rigidity greatly, as compared with the usual make of flattened-tube fork-end. In the fork crown the weakest feature of the ordinary double-plate pattern is the smallness of the brazing surface, which sometimes results in the tearing apart of the joint. This is remedied by fitting the fork blades into a practically continuous socket joining the crown plates, thereby so greatly increasing the brazing surface as to reduce the maximum stress on the solder, and to eliminate all chance of breakage.

Chain Stays.—The chain stays are perhaps the most important part of the frame of a cycle; they are certainly the part about which the greatest difference of opinion exists. Before the extreme importance was realised of a narrow tread for constituting a straight-running machine, round chain stays of ⅞ inch diameter were often used, which gave ample stiffness; but now that there is a premium on every ⅛ inch under 5 inches clear width between the pedals, it is necessary to reduce this diameter to about ⅝ inch. Now a tube of round section ⅝ inch diameter is only abont half as stiff as one ⅞ inch diameter of the same weight, and has only about 70 per cent. of the strength. It therefore becomes necessary to use a section giving greater rigidity and strength than the ordinary round tube. The choice lies between oval, rectangular, and D sections. The last of these has been chosen by the author as the most suitable, in consideration of the nature of the stresses to be met. The weight of the rider puts the chain stays in tension; but this tension is small compared with that produced when the foot is exerting its maximum pressure on the pedal. The nature of the deformation produced by the chain tension may be investigated by tightening up the chain, and then squeezing its upper and lower spans together. It will be seen that both of the chain stays are thereby bent towards the chain side, because, being connected by the back axle, one cannot move without the other; and the final result is a bending in four places, two on each side, namely, close to the bridge and close to the back axle. The chain stays designed by the author are shaped with a slight bend in the middle, so as to clear the crank end. This construction has been criticised as causing a bending moment at that point, tending to buckle inwards the stay on the chain side; but experiment shows that the total bending moment is not a maximum at that point, and that consequently the slight inward bend does no harm. On the other hand a sharp bend near the bridge is a source of weakness, which is best guarded against by using a steel casting at this point, instead of merely bending the tube. The bending moment, which is due to the back axle not being exactly in line with the back forks in some portions of the "chain adjustment," amounts in extreme cases to about 70 inch-pounds, which means only a small stress on the D tubes that are used. The stress, moreover, is perfectly symmetrical, and causes no lateral distortion of the frame. The advantage claimed for the radial or swinging adjustment—namely, that the axle is always in the centre line of the back forks—is thus of small account, and is far more than counterbalanced by the want of lateral stiffness in that adjustment. By the "chain adjustment" is meant the path of the back axle along the slot provided for the purpose of adjusting the tension of the chain; when the back forks are bolted to the axle, the weight of the rider is taken direct by the axle; but when the frame is brazed together at this point, the axle moves away from the point where the centre lines intersect.

D Tubes.—On the subject of D tubes for chain stays there exists some amount of misapprehension. They were introduced by the anthor partly because the flat inner surface is convenient for the nut on the back axle to be locked against, and partly because, for the same width and weight, they are more rigid than either round or oval tubes. It must be borne in mind that, in order to attain the requisite rigidity, it is necessary in general to increase the section of chain stays beyond what is required for mere strength; it is therefore the rigidity of the different sections that has to be compared, and not their strength. It has been argued by a recent writer on cycle construction that, weight for weight, a tube of semicircular section is only 1 per cent. stronger than a tube of circular section, if both are of infinitesimal thickness. Now the D tubes employed by the author are not of semicircular section, and they are at least 20 gauge or 0·036 inch thick. A semicircular tube is about 16 per cent. stiffer than a circular tube, weight for weight, if both are of infinitesimal thickness; and when the thickness becomes finite, the advantage is still greater. A ⅞ inch semicircular tube of 20 gauge or 0·036 inch thickness is about 25 per cent. stiffer than a ⅞ inch circular tube of the same weight, since the thickness of the latter must be about 17 gauge or 0·054 inch, and its mean diameter is therefore less. The section used by the author, however, is not semicircular, but much more resembles the shape of the letter from which it takes its name. Theoretically, a rectangular section is the best possible; but its appearance on a cycle is so hideous as to be out of the question. If for equal weight the relative stiffness of a tube of circular section, ⅞ inch diameter and about 17 gauge thickness, be represented by 100, then the results of tests of oval and D and rectangular sections, all three rolled from a round tube of $\frac{13}{16}$ inch diameter, will compare as follows:—

Round tube,	0·85 diameter	× 0·054 thickness,		relative stiffness,	100.
Oval ,,	0·65 wide ×	1·125 deep ×	0·036 thick,	,, ,,	119.
D ,,	0·65 ,,	1·070 ,,	0·036 ,,	,, ,,	136¼.
Rectangular	0·65 ,,	0·825 ,,	0·036 ,,	,, ,,	146½.

It will thus be seen that the D section now adopted is only about 7 per cent. less stiff than the rectangular, which is the best that can be rolled out of a round tube of the same diameter and to the same width.

Various webbed sections have from time to time been proposed and advantages have been claimed for them on the strength of tests which mainly show resistance to local crushing in one particular direction, and give no indication whatever of the value of the section when made up into a cycle. Tests made on webbed D tube, by brazing a plug into one end and loading the other, show that it is 6 per cent. less strong and 15 per cent. less stiff than plain D tube of the same weight and external size. It is important to realise that the material of a tube should be kept as far away from the neutral axis as possible.

Multicycles.—The necessity for lateral rigidity is even more apparent in multicycles than in single machines. It is found that any want of unison in the efforts of the riders has a disconcerting effect, which greatly detracts from the pace and from the power of going up hills. It is only by the employment of tubes of larger diameter that the increased distorting stresses can be properly met. The form of frame now generally adopted was first used by the author in 1895, and has for its principal feature a horizontal tube running from the bottom of the head, parallel with the top tube which starts from the top of the head; the lower line of tube is braced by means of light diagonals to a single bottom tube of 1¾ inches diameter. This form of frame, whilst not superior in strength or rigidity to that having diagonals running from the top tube to the bottom without an intermediate tube, possesses a great commercial advantage in the fact that frames can be built of different heights without altering the angles of the lugs simply by raising the top tube. It is advisable to unite the rear end of the intermediate tube to the back forks by a short fork, which increases the lateral rigidity. There seems to be a general tendency to duplicate the back fork in multicycles; but greater rigidity can be secured by means of a single fork of large section, provided that it is properly connected to the top of the rear seat-pillar lug. In the same way a single tube of 1¾ inches diameter connecting the various crank-brackets gives greater rigidity than the more usual arrangement of two 1-inch tubes, placed either side by side or one above the other. The method devised by the author of fixing the back axle by nuts locking against the inner surface of the chain stays, gives a rather wider spread to the back forks than is usual, which is an advantage in improving the bracing between the axle and the seat-pillar lug.

Chains.—The great advantage of a roller chain, when exposed to mud or dust, led the author to consider why the block chain was so generally admitted to be the faster of the two; and the conclusion he came to was that it is a question of smoothness of running. The roller-chain links were at least 1 inch long from centre to centre of eyes, whilst those of the block chain were alternately 0·4 inch and 0·6 inch. By shortening the links, therefore, to half an inch, he concluded that the roller chain would run more smoothly, and consequently be faster than the block chain. It was found indeed that roller chains of ⅝-inch pitch were already contemplated by the chain makers; but as this length is slightly in excess of the longer of the block-chain links, there is no advantage in smoothness or speed. It was questioned whether the chain and wheel of ½-inch pitch could be made a success in practice, but experience has fully justified the expectations on this point. The smoothness of running with gearing of this pitch is remarkable, whilst its excellent behaviour when covered with mud or dust renders a casing almost superfluous.

Gear and Crank Length.—The question of gear is so closely connected with that of crank length that they cannot properly be considered separately. For it is evident that a gear of 60 inches does not represent the same conditions with a 6-inch crank as when one of 7 inches is used; and similarly it would not be reasonable to expect that a leg 36 inches long will be suited by a length of crank which suits a leg 32 inches long. The length of crank must be decided by the rider's natural length of stride, and the ratio of multiplication of gear to length of crank must depend upon his muscular development, both of which data may be approximately ascertained by measurement. The gear is then the product of the two factors so determined. The maximum ratio of multiplication for road riding is about 12 times, and the minimum about nine times. The maximum length of crank may be taken as about 7½ inches, and the minimum 6 inches. Hence the gear may vary from 90 inches down to 54 inches.

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

*** *At the request of a number of subscribers we are pleased to announce that for the future we have arranged to more thoroughly cover the field of completed Patents referring to the Motor-Car Industry, by reproducing the latest Specifications and Diagrams.*

Specifications Published.

14,756. Oil Engines for Propelling Carriages, &c. James Roots, 100, Westminster Bridge Road, London. July 3rd, 1896.

Fig. 1 shows the method of connecting the valve and power countershaft to the motor.

Fig. 2, the plan of a portion of the frame of an oil motor vehicle, showing the friction discs and rollers.

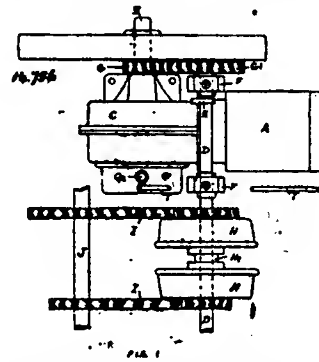
Fig. 4 is an elevation of a portion of an engine, showing the arrangement of the starting and automatic burners.

In **Fig.** 1, A is the cylinder, B the crank shaft, C the enclosed and airtight crank pit, D the half speed shaft, E the cam for operating the exhaust valve, F the bearings carrying the half speed shaft, which are fixed to the motor, a third bearing not shown is fixed to the vehicle frame, G, the chain wheel on the crank shaft, having half the number of teeth of the chain wheel, G 1; H, H, are friction clutches operated by a fork lever not shown, fitting in the groove, H^1, by which either of the chains, I, I, are thrown into gear to drive the axle or shaft, J.

The exhaust valve and the method of operating it by the cam, E, are not shown, and may be of the usual construction.

The bearings, F, are fixed to brackets which are bolted to the motor. The countershaft, D, is parallel to the crank shaft, and is driven by the chain and chain wheels, G and G 1, at half the speed of the crank shaft. It carries the cam, E, for operating the exhaust valve, and transmits the power of the motor to the shaft or axle, J. The countershaft, D, thus serves the double purpose, it is conveniently placed parallel with the other, and runs more silently, being driven by a chain.

In Fig. 2, K is the frame of the vehicle. L L the vehicle wheels, rigidly fixed to the portions of the axle, L 1 and L 2; M, M^1, are the friction discs fixed at the other ends of the axle shafts, L 1 and L 2; N, N^1, are the friction rollers, O is a toothed wheel keyed to the shaft, P, which is driven by the motor, it gears with the wheel, O^1, which is fixed to the shaft, P^1. The gear wheel, O^1, has the same number of teeth as the wheel, O, the shaft, P^1, therefore rotates at the same speed as the shaft, P, but in the opposite direction. The rollers, N, N^1, slide on feathers on the shafts, P, P^1, and are simultaneously operated by a lever (not shown) from the seat of the carriage. In the position of the friction rollers, N, N^1, shown, if they are moved nearer the bearings, P 4 and P 5, they cease to drive as the pressure lessens at the peripheries owing

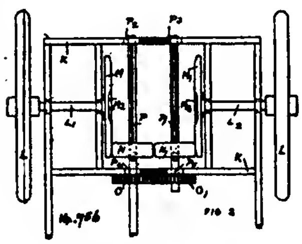


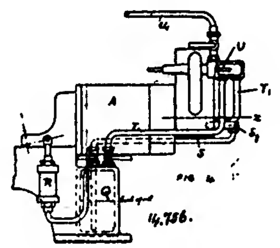
to the turned away edges of the discs, M, M^1. If the rollers, N, N^1, are moved toward the centre of the discs, they increase the speed of the vehicle until they reach the hollowed out centres, M^2, M^3, when they again cease to drive, if the movement be continued toward the bearings, P 2, P 3, then the vehicle is reversed. Means may be provided (not shown) for compressing the shafts, P and P^1, together when it is desired to reverse or to place the rollers at a different position on the discs.

The shaft bearings are fitted in a guide and pressed apart by a spring, but prevented from exceeding a certain adjusted distance by set screws, so that the shafts need not be out of the parallel by more than $\frac{1}{16}$ inch. One shaft may be the counter shaft of the motor, or may be driven by the motor in any convenient manner such as a chain and chain wheels, or flexible coupling.

A ratchet and pawl may be fitted, if desired, in some intermediate position between the wheels.

In Fig. 4, Q is the lamp reservoir which is not more than half filled, so as to allow room for compressed air at the top of the reservoir. R is the air pump operated by means of a bell crank lever connected to the side shaft of the engine (not shown). S is the pipe conveying the oil under pressure to the burner, S 1, a pressure burner of usual construction. T is the pipe conveying the air blast from the reservoir, Q, to the oil feeder, U (U 1 is the oil supply pipe). In the space round the oil feeder, U, which is operated in the usual manner, described in my former specifications, may be fitted cotton or other absorbent material.





From U the blast of air carries the oil fed thereto, by means of the pipe, T I, to the pipe or channel surrounding the flame and ignition tube within a casing. The pipe or channel terminates in a nozzle which directs the air blast flame upon the ignition tube. In starting the engine, Fig. 4, the cock on the pipe, T, is closed, air is pumped to a pressure of a few pounds per square inch in the reservoir, Q, the cock on the pipe, S, is opened and the burner, S 1, started in the usual manner.

After the engine is started, to obviate the uncertainty of the type of burner, such as S 1, the automatic burner is brought into action, by closing the cock on the pipe, S, and opening the cock on the pipe, T.

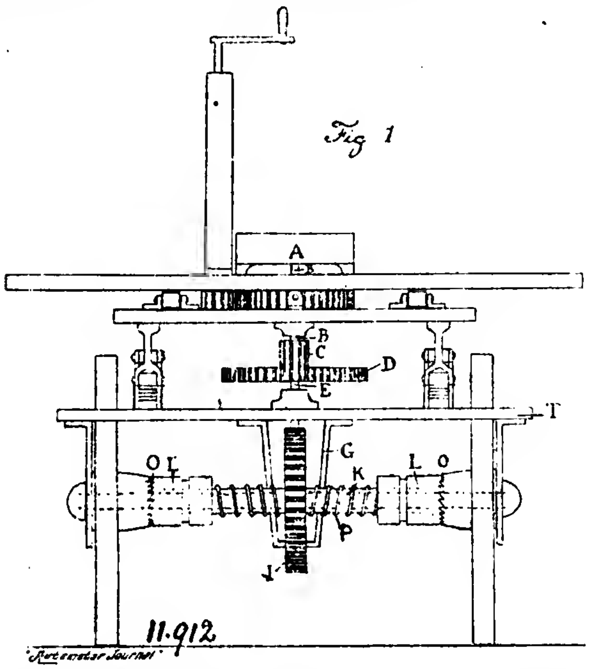
The engine continues to pump air by the pump, R into Q, which is conveyed by the pipe, T, and sweeps off the oil fed by the feeder, U, and both are conveyed by the pipe, T 1, to the coil, V.

In Fig. 1, the motor is started by the usual starting lamp with a separate reservoir. The air chamber, Q 1, is used as a cushion chamber only for the air blast, to prevent variation and intermittence in the air supply, and no oil is placed in it. Q 2 is the cap of the suction and delivery valves of the air pump formed by the front face of the working piston and the enclosed air-tight crank pit chamber, C. Air is delivered from the crank pit, C, to the chamber, Q 1, by the delivery valve under the cap, Q 2, and conveyed by the pipe, T, to the oil feeder of the same construction as U, in Fig. 4. The rest of the automatic burner is of the same construction as in Fig. 4.

11,912. Autocars, or Self-propelling Vehicles. Charles Casman, 4, Chaussée d'Aerschot, Louvain, Belgium. June 1st, 1896.

This invention has reference to autocars, or self-propelling vehicles, with a turbine as the motor.

A is the turbine (for instance, a steam turbine) for imparting motion to the vehicle. B is a vertical shaft, on which is a fluted or toothed pinion, C, by means of which it transmits the motion of the turbine to a fluted or toothed wheel, D, keyed on the upper part of a vertical shaft, E, which extends through the frame, T, of the vehicle, and whose lower end is mounted in a



hanger, G, in such a manner as to rotate freely therein. The vertical shaft, E, is, on a level with the axle of the vehicle, provided with an endless screw or worm, which gears with the teeth of a toothed wheel, I, keyed on a hollow shaft, K, in which or through which passes the axle of the vehicle. The hollow shaft is square in cross section, and each of its ends is provided with a clutch adapted to slide freely along the said shaft, and to engage with a toothed rim or ring of teeth, O, on the boss or hub of the adjacent wheel of the vehicle. Springs, P, arranged preferably around the hollow shaft, K, act to constantly press the clutches, L, into gear with the toothed rings, O.

The motion of the toothed wheel, I, is thus transmitted to the wheels of the vehicle by means of the shaft, K, and the clutch mechanism or coupling, L, O.

9,982. Gas, Oil, or other Internal Combustion-engines. Howard Lane, 184, Corporation Street, Birmingham. May 11th, 1896.

Consists in the application of a regenerator or heat interceptor within or in continuation of the cylinder of the motor placed in such a way in relation to the piston and the inlet and outlet orifice or orifices that all incoming air or combustible gases must pass in one direction through the regenerator to obtain access to the piston, and after ignition and expansion the products of combustion or the greater portion of same must pass in the reverse direction through the regenerator. The regenerator is constructed of layers of metallic wire gauze or other sheet material or of other permeable and subdivided form of rapid conducting and absorbing power offering a large surface, yet of such a structure that although individual portions of the fabric will quickly receive heat yet they will not readily impart that heat from one portion of the structure to another. Metallic gauze is suitable in that the points of contact formed by the places where the wires cross each other offer very small surfaces of contact between the sheets.

To intercept the heat that would otherwise be lost in the exhaust or discharge of the motor cylinder and by connection through its end, the regenerator in size and shape may coincide with the cross section of the cylinder and cover the end.

15,832. Motors for Road Carriages, &c. William Henry Dugard, Vulcan Mills, Bridge Street West, Birmingham. July 17th, 1896.

The motor consists of a turbine actuated by steam or other fluid pressure, the bucket disc of which turbine is arranged on a vertical spindle or shaft.

The invention also consists of providing the vertical spindle or shaft of the bucket disc with loosely-fitting bearings so as to permit the bucket disc and shaft to partake of a slight radial sliding or lateral motion under the centrifugal force of the rotating bucket disc, the space between the ends of the spindle or shaft and its bearings being occupied by steel springs for limiting and controlling the radial sliding motion or lateral movement of the spindle or shaft; the addition to or combination with the turbine of one, two, or more supplementary nozzles, the communications between which and the steam passage of the turbine are opened and closed by valves controlled by the pressure of the steam; the use of the variable speed belt gear consisting essentially of a series of pairs of pulleys on which loose bands are situated, one or other of the said pairs of pulleys being put into gear by the pressure on the band of a tightening or jockey pulley; and, lastly, of arranging the bottom bearing for the driving pulley shaft in a lever capable of being turned in the direction proper for bringing the periphery or acting surface of one of the driving pulleys in direct contact with the periphery or acting surface of the corresponding pulley on the driven shaft so as to obtain a reverse motion of the said shaft and effect the backing of the vehicle.

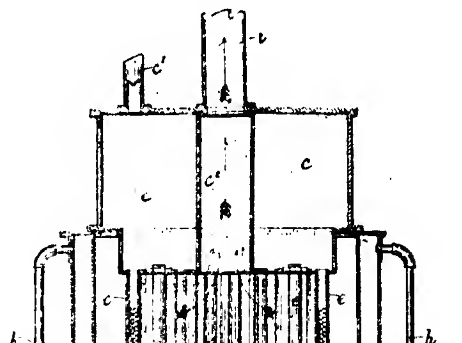
4,284. Cycles and Motor Cars. Laurence Redmond, 126, Sandford Road, Ranelagh, Dublin. February 11th, 1897; Accepted, May 29th, 1897.

This invention relates to improvements in cycles and motor-cars, and has for its object the application of leverage for the purpose of applying pressure to break rods.

It consists of the combination with a preferably curved handle pivoted to transverse handle bar with ball bearing joints or with loose, adjustable, detachable collars, or other joints, which are free to move on said transverse handle bar of a central lever also pivoted to transverse handle bar with ball bearing joints, or with loose, adjustable, detachable collars, or other joints, which are free to move on said transverse handle bar and engaging in said preferably curved handle. The depression of said preferably curved handle causes central lever to be also depressed, the lugs of central lever pressing against vertical piece of an inverted T-shaped crank, thus causing the other arms of said crank to rise and fall respectively, thereby applying pressure to break rods.

11,713. Steam Generators and Furnaces for Road Carriages, &c. Preston Davies, Spencer House, West Hill Road, Southfields, Surrey. May 29th, 1896.

A cylindrical or other casing, *a*, has a second casing or jacket, a^1, at a certain distance therefrom, so as to form an annular space, *b*, wherein is placed the naphtha or other volatile liquid intended for fuel. Upon or at the upper end of this annular casing is fixed a hollow ring, *c*, which communicates with a conical-shaped vessel, *d*, placed centrally and apex downwards, within the space contained by the casing, *a*, and which vessel, *d*, is suspended by and communicates through a set or series of tubes, *e*, *e*, with the above-mentioned hollow ring. The ring, *c*, is intended to form a steam space or dome, the tubes, *e*, and conical vessel, *d*, form the water or liquid space of the boiler, and the space, *f*, contained or enclosed by the annular casing, *a*, forms the furnace or combustion chamber of the generator; c^1 is the steam pipe for conducting the steam from



the steam space or dome, *c*, to the engine or the like; d^1 is a blow-off pipe, fitted with a suitable stop-valve for blowing off sediment or dirt from the conical vessel, *d*. The feed-water or other liquid is preferably introduced into the water or liquid space through one or more tubes, *g*, entering the lower extremities of one or more of the tubes, *e*, and the normal water level in the latter might advantageously be situated at a point about three-quarters of their length, as shown.

To introduce the vaporised liquid fuel into the furnace or combustion chamber, pipes, *h*, lead from near the upper part of the annular casing, a^1, at two or more points opposite each other; their free extremities terminate in nozzles, h^1, so situated as to impel the blow-pipe flames that would result from the burning vapour against the conical-shaped vessel, *d*, after impinging against which they take an upward course, and having passed between and enveloped the tubes, *e*, connecting the said conical vessel with the hollow steam ring or space, *c*, would finally pass away to the uptake, *i*, through the central aperture, c^2, in the said hollow steam ring, *c*.

ACCUMULATOR TRACTION ON RAILS AND ORDINARY ROADS.*

WHILE electric traction on the trolley system has proved on the whole an unqualified success, both from a technical and financial point of view, traction by means of accumulators could, until quite recently, only be pronounced a failure, and all that even its most ardent advocates can plead for is the substitution of the term "qualified success." However, at the present time, signs are not wanting that promise at last success for accumulator traction. The progress made in the manufacture of secondary batteries, and the experience gained with regard to the best mode of using them, not only warrant that belief, but, what will no doubt prove more convincing, relatively good results have already been obtained.

It will be remembered that ever since accumulators were produced on a commercial scale attempts were made from time to time to use them for traction purposes, but all these experiments up to a short time since—although frequently hailed with great enthusiasm—only led to disappointment, from a commercial point of view.

An investigation of the causes which militated against success might prove useful, and will show that they may be divided into two classes, viz., inherent defects in the accumulators themselves and mistakes in the mode of their application.

The various difficulties and losses can be obviated by adopting a system which will allow of the batteries being treated as a mechanically and electrically well connected whole, either by being placed in the cars or preferably slung to the frame, or carried on a separate car—apart from the sub-division in groups for coupling in parallel or series during discharge. Where the conditions of working render it desirable, the motor, or motors, could also be fixed in the battery car, which would then assume the character of an electric locomotive; but in any case, whether carried in the car itself or slung to the frame, or carried on separate wheels, the battery should not be sub-divided and handled in the old way, but should always be treated as an indivisible unit. The obvious advantages gained by this method are the absence of lifts or similar contrivances, good connection between cell and cell, no corroding contacts, no loss of current through leakage, less wear and tear of the batteries, and consequently easier management and reduced expenditure. The importance of obviating the exchanging of batteries has been fully recognised on the Continent, and the methods of working in Hanover and Paris offer interesting illustrations of how this object has been attained.

In Hanover, as is well known, a combined system of trolley and accumulators is in use. The batteries are charged from the trolley *en route*, and an additional charge is given to them on their return to the car shed. This installation is on a sufficiently large scale to render the financial results of commercial value, and it is gratifying to see from the official report that the results for the year 1896 were pronounced to be in every respect satisfactory. The cost of maintenance is said to have been accurately ascertained, and found to average per car and month 40*s.*, which, at an average mileage of 90 per car and day, corresponds with ·177*d.* per car mile. The directors anticipate that this cost will be increased somewhat, but they are also confident that it will in no case exceed 60*s.* per car and month (which amounts to ·266*d.* per car mile) even in those years when the quicker deterioration of the plates will occur. It must be understood that the cost of maintenance includes renewals of plates to keep the latter always in good condition, so that the additional depreciation is reduced to a rate not higher than that of the renewal of other parts of the machinery. Based on the actual experience gained, this rate has been fixed at 6 per cent., and with an accumulator car covering between 31,000 and 34,000 miles during the year on this mixed system, accumulator traction incurs an additional expenditure of ·4*d.* per car mile, as compared with the trolley. Taking into account that in the absence of the accumulators the trolley system would have to be installed throughout the whole line

* Excerpt of a paper read by L. EPSTEIN, Esq., M.I.E.E., &c., before the Institution of Electrical Engineers, November 11th, 1897.

at an outlay of £2,000 per mile of track, and further considering the maintenance of the overhead system and the saving in the wear and tear of the trolley, which is, of course, at rest while the accumulators are supplying the current, it is computed that even on the most unfavourable assumption the extra cost of the combined system compared with the overhead system alone does not in Hanover exceed ·2*d*. per car mile.

It may be of interest to mention here that the running expenses of the electrical system, including driver, amounted to 2·22*d*. per car mile.

This system, although so far satisfactory, is open to certain objections, the foremost being the dead-weight of the accumulators carried on the trolley wire section. It might be found more advantageous to place the batteries in a frame slung to the car, or in dummy cars, either of which could be picked up at the end of the trolley section, while the charging of the accumulators could still be effected in the same manner from the trolley wires, the only difference being that the charging would take place at fixed points instead of *en route*.

A different system is employed in Paris, where the Société des Moteurs have installed and are working a line about 12 miles long at the same cost, including depreciation, as horse traction.

Never losing sight of the object in view, viz., to approach in the mode of working as far as possible the overhead or conduit system, the special method to be adopted will depend upon local circumstances. While in one case the batteries may be advantageously carried in or slung to the car, in others it will be found desirable to place them in dummies, which latter might also carry the motors, as an alternative to the motors being fixed in the cars. A dummy with a battery sufficient to propel a 52-passenger car for about eight hours will weigh, complete, about three tons, the dummy itself, with axles and wheels, weighing about three-quarters of a ton. As each ton propelled under normal conditions incurs an expenditure of about ·4*d*., the extra weight of the dummy would increase the expense by about ·3*d*. per car mile. It is, however, obvious that this increase represents only a small fraction of the expenditure which is incurred when the accumulators are handled in the old manner, apart from the saving in wear and tear of the cars and of the batteries.

However excellent the method of using the battery may be, it will avail but little if the battery itself be lacking in the necessary qualities, and it may safely be asserted that the success or failure of accumulator traction will be decided by the merits of the accumulator. In order to lend itself satisfactorily to traction purposes, an accumulator must, in addition to all the good points possessed by a successful lighting cell, present special features of its own. Although lightness may not be the main consideration, yet it is a very important one. Again, the cell must not only be able to withstand jolting without shedding of material and high discharge rates without buckling, but, moreover, it must not decrease in capacity while in use, as this would necessitate alteration in the time-table relating to the charging of the batteries, and interfere with the general arrangement. The battery, furthermore, should not require frequent overhauling, and the repairs should be neither more numerous nor more costly than those of any other part of the machinery. We all know that in the past batteries left very much to be desired. Some of the positive plates deteriorated much sooner than others, and this led first to the practice of replacing them by less damaged plates taken from other cells, and finally to that of converting part of the negative section into positives. After some time the original array had dwindled down to a small fraction, consisting of the least injured remnants, which were occasionally referred to as a proof of the long life of the type they represented. As a battery naturally consists of a large number of cells, and each cell again consists of a large number of plates, the overhauling and repairing proved a very serious item—in fact, in many cases the heaviest item of expenditure.

The nearest approach to an ideal cell for traction purposes will probably be one in which the positives are of the Planté type, with a large extent of surface, the layer of active material relatively thin, but in most intimate contact with the metallic lead out of which it has been formed. As is well known, while the capacity of a plate is determined by the volume of active material, the rate of charge and discharge depends upon its surface, and as it is quite feasible by means of ribs or protusions, without unduly interfering with the mechanical strength of the plate, to extend its area to about 10 times that of the plain surface, it follows that the current densities obtainable will be increased in the same ratio. It is further essential that the acid should have free access to all parts of the active material, and such is naturally much more the case with a Planté plate, offering a largely extended surface with a thin coating of peroxide than it would be in a plate with a plain surface, where the active material forms a relatively thick layer. Not only is the contact between active and conductive parts less perfect in the pasted plate, but in addition thereto, as the acid in the pores of the active part is liable to become exhausted, especially with heavy discharge currents, while the interstices are too narrow to allow of a quick diffusion of the electrolyte, the electric action may be seriously interfered with, although there may still be a sufficient quantity of undischarged active material.

As regards good negative electrodes, positives of the above description, after having been reduced, may be employed with advantage, or lead oxides or salts may be used, as the finely reduced lead is a much better conductor than peroxide of lead; but care should be taken to secure the best possible contact between such material and its support, and so to select the materials intended to become active that they will, after full formation, produce a layer of the highest possible porosity consistent with mechanical coherence.

It has been found by experiment that the exhaustion of a positive plate or section of a cell effects a gradual falling in the E.M.F., while as soon as the negative electrode is exhausted the E.M.F. falls very rapidly. For this reason, and as it is obviously advantageous to have as little variation in the E.M.F. of the battery as possible, I would suggest, for traction purposes, to use negative sections of higher capacity than that of the corresponding positive sections.

In the interest of economy, the formerly much-recommended overcharging must not be too freely indulged in. Such overcharging can easily be guarded against by using recording instruments, or by other suitable means, while when charging at constant potential the battery will itself guard against over-feeding by effectively opposing, at the proper time, the charging current. The recommendation to overcharge the cells *occasionally* may, however, be followed with advantage, the beneficial result consisting not so much as was formerly supposed in the actual improvement of the electrodes, but in the thorough mixing of the electrolyte, which is liable to vary in S.G., being densest at the bottom of the cell and decreasing towards the surface, thus leading to unequal action in different parts of the plate. Another device for equalising the action over the whole surface consists in making the electrodes taper towards the bottom, with the object of compensating for the higher density and better conductivity of the electrolyte there by increasing the distance between electrodes of opposite polarity.

We are now, however, confronted with the all-important question of the cost of depreciation of the batteries. If we consider a battery in a car for 52 passengers with an average running weight of about 12 tons and an average mileage of 100 per day, equal to 1,200 ton miles per day, we find that at the rate of 80 watt-hours per ton mile the daily electrical expenditure is 96 units, or, if working at 400 volts, 240 ampère hours. It is, of course, immaterial for our calculation what the voltage is, as the cost of renewal of either a small number of large electrodes or a larger number of small electrodes will be practically the same for the watt-hour capacity. The cost of renewing the positive section of a cell of such capacity should not exceed, including manufacturer's profits, 10*s*., and, assuming two discharges or their equivalent a day, we may reasonably expect a useful lifetime extending over 1,500 discharges. The battery doing work, therefore, during 750 days and covering 75,000 car miles, the cost of renewing the positive sections in 220 cells will amount to £110 or ·35*d*. per car mile. That this estimate errs on the safe side is borne out by the experience gained in Hanover, although it seems that the batteries used there are of greater weight than is necessary.

Given a good battery and having adopted a system best suited to the conditions of a given line, and in any case obviating the necessity for handling the batteries, we should arrive at a working cost approximately the same as on the trolley system—the extra expenditure caused by the greater weight of the self-contained car being balanced, as is shown in Hanover, by corresponding advantages gained.

While on tram-lines accumulator traction must prove its superiority over rival systems in order to be adopted, there is another large field in which the use of batteries is a matter of necessity. I refer, of course, to traction on ordinary roads.

The tractive force on ordinary roads is naturally subject to much greater variations than that on rails. I think, however, that on good roads paved with asphalte or wood and in fairly good condition, the tractive force of vehicles as hitherto built should, on the level, not exceed 60 lbs. The weight of an electrical vehicle to carry from two to four passengers, with motor and battery complete, will be about 30 cwt., which includes a battery with a weight of 9 cwt. A battery of such weight ought to be sufficient to supply current for a four or five hours' run, at an average speed of eight miles on the level and four miles up a gradient of 1 in 24. The power on the driving axle will be about 2 effective H.P. in the former case, and about 3 effective H.P. in the latter; and, assuming a combined efficiency of motor and gearing of 65 per cent, the battery will have to furnish discharges at the rate of 2,208 watts and 2,812 watts respectively.

With a battery efficiency of 70 per cent., the charge to supply one hour's actual run requires about three units, which, at an estimated cost of 2*d.* per unit (a sum that should certainly not be exceeded, whether the current be generated at the Company's own stations, or taken from a public supply), corresponds with a cost of ¾*d.* per mile. It may therefore be anticipated that electric carriages plying for public hire should be able successfully to compete with horse-drawn vehicles for a similar purpose, provided that the wear and tear of the accumulators is not excessive. The favourable financial results would not be impaired even if the cost of maintaining the accumulators should exceed the rate of 10 per cent. per year, said to be quoted by some manufacturers. The time during which such accumulators have been at work is probably too short to prove whether the batteries can be maintained at such a remarkably low rate.

Reliability of the battery, obviating the necessity for frequent examinations and tests, and for remedying partial defects, is again of much higher importance than—within reasonable limits—the lifetime of the whole battery, as will become evident from the following consideration. Assuming the average mileage made with one charge to be 40, and estimating the cost of renewing the positive section at 10*s.* per cell, or £20 per battery of 40 cells, the cost of renewal per mile would be as follows:—

If renewed in 8 months = 240 days, after 9,600 miles, ·5*d.* per cab mile.
If renewed in 12 months = 360 days, after 14,400 miles, ·33*d.* per cab mile.
If renewed in 16 months = 480 days, after 19,200 miles, ·25*d.* per cab mile.
If renewed in 24 months = 720 days, after 28,800 miles, ·166*d.* per cab mile.

If the average cost of a battery be £60, and if it should become necessary to renew all the positive sections—even after as short a time as 12 months after having run 14,400 miles—it is true that the cost of renewals (£20) will equal 33 1-3 per cent. of the first cost, but this only equals one-third of a penny per cab mile. On the other hand, even with batteries having a longer life but necessitating supervision and slight repairs, the wages incurred and the cost of material would, judging from the experience gained in tramway work, certainly amount to a much larger sum than the cost incurred in renewing the positive sections, even in a comparatively short time. Besides, in such cases more sets of batteries per car would become necessary, increasing not only the first outlay but the charge for interest and depreciation, and thus considerably swelling the total cost.

Lightness of batteries for ordinary roads is of much more importance than it is on tram lines, not only on account of the heavier energy expenditure which is necessary to propel a given weight, but the more so as the battery will represent a larger portion of the total weight of the vehicle as compared with tramcars. In large towns it would be an advantage to use batteries which are interchangeable, and to make arrangements with public supply companies to charge the batteries and always keep a number ready for use.

Worm Gearing.—There seems some prospect of worm gearing coming into favour again where a large reduction ratio is needed. Such gears have the advantage of being comparatively noiseless, but have, in the past, had an evil reputation, says *Engineering*, for excessive frictional loss. More recent work with accurately-made wheels has shown that this loss need not necessarily be very large. Professor Stodola, of Zurich, has obtained an efficiency of 87 per cent. when using worm gearing to transmit 21 H.P., the worm running at 1,500 revs. per minute. This worm was 3·15 inches in diameter, the pitch being 3·2 inches, and the wheel, which was of gun-metal, had 28 teeth. Similarly, Mr. E. Kolben has also obtained excellent results with worm gearing; whilst in America the Sprague Company, using the Hindley form of worm, have, it is stated, got remarkably high efficiencies with this class of gearing, which they use for electric lifts.

THE AUTOMOBILE CLUB.

This club, founded by Mr. F. Simms and other gentlemen, was formally opened on the 8th inst. by Mr. R. Wallace, Q.C. It is unnecessary to say anything as to the necessity of establishing an influential Automobile Club, as this is self-evident. The new club has secured very handsome and commodious premises at Whitehall Court, overlooking the Embankment Gardens. These premises, which consist of six rooms on the ground floor, appear admirably suited to the requirements of a club of this kind, inasmuch as in addition to being most centrally situated, they are exceptionally suited for the approach of motor carriages, from the fact that they are surrounded by roads which are practically free from ordinary traffic.

The opening of the club was made the occasion for a reception by the chairman, Mr. R. Wallace, Q.C., who in the course of an able and eloquent speech put forward the objects and aims of the club, which, judging from the enthusiasm and spirit with which its birth was acclaimed, bids fair to become a great success.

The chairman announced that the organising committee had already received about 200 applications, amongst which he noticed the names of the Earl of Shrewsbury and Talbot, the Lord Suffield, Sir Douglas Galton. Professor Kennedy, James Swinburne, Esq., Sir Bernard Samuelson, K.C.B., A. J. Walter, Esq., J. C. Graham, Esq., Captain Ironside Bax, W. Worby Beaumont, Esq., Earl of Carnarvon, the Earl of Galloway, General Sir Arthur Ellis, K.C.M.G., Sir William Neville Abdy, Bart., Sir Trevor Wheler, Sir George Thomas, Bart., Major-General England, Major-General Montgomery, the Hon. Evelyn H. Ellis, the Hon. Reginald Brougham, the Hon. F. St. John, the Hon. Captain J. H. Berkeley, the Hon. Cecil Duncombe, the Hon. C. S. Rolls, Colonel Magrath, Colonel Lee, Captain Cragg. Captain George D. Sampson, Lieut.-Colonel Wheler, Major Wheler, W. H. Preece, Esq., C.B., H. E. Sherwin Holt, Esq., Paris Eugene Singer, Esq., John Henry Knight, Esq., Frederick R. Simms, Esq., Hiram S. Maxim, Esq., George Edwardes, Esq., Herr Gottlieb Daimler, Jesse Ellis, Esq., Walter Arnold, Esq., Arthur Paget, Esq., the Rev. E. S. Lawrence, Dr. Leadam, Dr. Hutchinson, Dr. Shelly, &c., &c.

It will thus be seen that the club does not lack influential support

The solicitor, Mr. John B. Purchase, having reported about the registration and legal matters as to the constitution of the club, the secretary *pro tem.*, Mr. C. Harrington Moore, submitted the rules for adoption and confirmation on the meeting, which were unanimously carried. A discussion on the club's programme for 1898 followed, in which some excellent suggestions as to lectures, &c., during the present season, as well as competitions, prizes for designs, &c., tours for members, the erection of signposts on highways, and other matters were put forward.

Just before the close of the meeting Colonel Lee proposed a vote of thanks to Mr. Frederick R. Simms, on whose initiative the club was formed, and who had in such a spirited manner taken upon himself to guarantee the first year's expenses of the club to a considerable amount, and had taken such a prominent part in the organisation of the club, and devoted so much time to the same.

Mr. Simms replied, and said he could not take all the praise so kindly given him, because he certainly thought a large amount of the credit belonged to Mr. C. Harrington Moore, secretary *pro tem.*, who had worked so indefatigably and assisted him in such a very able manner.

The chairman then formally declared the premises open for the use of members, and a hearty vote of thanks was accorded him for having presided at the meeting. The meeting was followed by a display of motor carriages, arranged for members and their friends. This started at Whitehall Court and was confined to the Embankment. All the general arrangements made by the club committee worked admirably.

The Motor-Car Club Meet.—The second annual meet of this club took place on Monday, November 29th. About 39 automotor vehicles put in an appearance as against more than 100 which had been expected. The Hôtel Métropole was the rendezvous, and Sheen House, Richmond, the objective. As for the vehicles themselves there was little that called for remark; most of them had Daimler motors. There was an "Arnold-Benz," a "Headland," four electric cabs, a couple of Bollée voiturettes, and a De Dion tricycle, and a few other makes. Nothing in the shape of novelty was shown, and beyond the fact that the only progress made since last year was an improvement in details there was little to note.

G 3

THE IDEAL TRACTION CELL.

In commenting upon Mr. L. Epstein's paper read recently at the Institution of Electrical Engineers, an excerpt of which will be found in our present issue, the *Electrical Review*, in a leading article, says:—"Mr. Epstein's ideal cell for traction purposes is not exactly what we look forward to. We quite agree that such a cell must be able to withstand jolting without shedding and high discharge rates without buckling, and that, moreover, it must not decrease in capacity while in use; but our ideal cell is very much lighter than anything Mr. Epstein has in view. No positive plate will, in fact, come up to our ideal until local action between the active material and its support has been so far obviated or reduced as to allow of this support being of no greater weight than that requisite for conduction, whilst at the same time its permanency is greatly increased. These may be hard conditions, but we believe that they are attainable. In regard to the negative element, there appear to be no great difficulties to overcome; but we do not agree with Mr. Epstein that a reduced Planté positive is the best that can be provided. The positive element tends always to increase in capacity; the proposed negative, initially of comparatively low capacity, would tend always to decrease in this direction. It seems obviously desirable—as, indeed, Mr. Epstein himself elsewhere points out—that the capacity of the negative element should initially be considerably greater than that of the positive element, so that at no time it should fall below it."

The American Society of Mechanical Engineers.—We have received copies in advance of the papers read last week in New York. Many of these papers, although not of immediate interest to automobilists, are of high scientific and technical value to engineers, and we hope to give some excerpts from them.

The London Electric Cab Cells.—According to a statement made recently by Mr. Manville at the Institution of Electrical Engineers, it appears that the cabs carry 40 cells, and the current on level wood pavement was 30 ampères with 80 volts pressure, and this increased up to 40 or 45 ampères on rough roads. He had seen the ammeter point to 120 on the Savoy Hill.

THE COULTHARD STEAM WAGON.

Messrs. Coulthard and Co., of Preston, have been working on the heavy steam wagon question for some time, and have succeeded in building a vehicle which is characterised by many good features, and which is likely to be largely used for heavy van traffic. As will be seen from the accompanying illustration, the driving-wheels are carried in horn plates—the only proper method in our opinion; and are, moreover, placed in the rear; the fore-wheels are also carried in a very strong frame, and this enables the severe lateral stresses to be withstood. There are two independent brakes which give full control over the vehicle when descending gradients. The motive power is supplied by an oil-fuel tubular boiler placed on the fore part, the oil used being ordinary burning oil or paraffin. This wagon can carry with ease a load of two tons on any ordinary country road, and where the roads are good and the gradient not steep, as much as three tons can be carried. It will thus be seen that for cities such as London this wagon could be most usefully and economically employed. The speed is from 4 to $4\frac{1}{2}$ miles per hour loaded, and from six to seven light. Owing to the excellent reversing and steering gear the wagon can be manœuvred much easier than any horse-van. Messrs. Coulthard also make steam tipping carts and lorries.

The Coulthard Steam Wagon.

Messrs. Peek, Frean, and Co. Adopt Motor-Vans.—Messrs. Roots and Venables, of 100, Westminster Bridge Road, S.E., have obtained an order from Messrs. Peek, Frean, and Co., biscuit manufacturers, London, for an oil motor-van to carry one ton. The van is required for the delivery of biscuits. Great competition took place among motor makers for this order, as it is understood that if the first van gives satisfaction to Messrs. Peek, Frean, and Co., further orders are to follow; and as this firm uses 170 vans for the delivery of their goods, the order is worth having. We understand that the benzoline spirit vehicles, including the Daimler and Anglo-French, and the known steam vans of this country were among the competitors, and that Messrs. Peek, Frean, and Co.'s representative tested them. The order, upon somewhat stringent conditions, has been given to Messrs. Roots and Venables chiefly owing to the fact that they make a practicable oil motor using heavy oil. Messrs. Peek, Frean, and Co. considered that safety of working and running was the essential condition, and this they thought could not be obtained with a benzoline spirit motor.

TRACTION ENGINE BY MESSRS. CLAYTON AND SHUTTLEWORTH.

Messrs. Clayton and Shuttleworth commenced the manufacture of traction engines about 40 years ago, and, although many different forms of road engines have been invented since that date, the principle introduced by them has continued in practical use.

In Clayton and Shuttleworth's early traction engines the cylinder was placed at the smoke-box end of the boiler, while the crank-shaft was at the fire-box end of the engine. The power was transmitted from the crank-shaft to the main axle by spur gearing. When the Stamp End firm were making traction engines on the above lines, the other firms engaged in this branch of engineering were using pitch-driving chains, and in most cases the engines were arranged the opposite way about—viz., like the portable engines of the day, the cylinder was placed on the raised fire-box shell, and the crank-shaft at the smoke-box end of the boiler; a long driving chain transmitted the power from the crank-shaft to the main axle or the driving wheels. The driving-chains were retained till about 1871, when spur gearing was introduced by some other firms; while Clayton and Shuttleworth had been using spur gearing since 1860.

Messrs. Clayton and Shuttleworth have introduced a new design of traction engine, which we illustrate herewith, in which are embodied every modern device for obtaining the best results. The engine is distinguished for great strength in all the parts subject to strain, the most excellent workmanship, and the highest economy in fuel and repairs. The boiler is constructed throughout of steel, and stayed in a similar manner to the best railway locomotives. It is of ample capacity, and of extra strength for working safely at 140 lbs. per square inch. The top of the fire-box is not strengthened by the ordinary heavy and faulty roofing bars, but is stayed directly to the arch-plate in an efficient manner, thus enabling the fire-box top to be kept free from scale and sediment. The smoke-box is constructed independently of the barrel-plate, so that it can be easily renewed when corroded, without having to cut out the tube-plate.

The cylinder is efficiently steam jacketed, the jacket space forms a dry steam receiver, the circulation of the steam is secured in the jacket by the working steam from the top rushing into the stop-valve, which is placed at the highest point.

All tendency to prime is removed by the manner in which the steam is conducted into the cylinder, coupled with the internal arrangement of the cylinder and the proportions of the boiler. Dry working is obtained under the heaviest loads at all speeds. The flange of the cylinder is extended beyond the ends of the cylinder so as to increase the bearing surface on the boiler barrel. There is no steam joint under the cylinder, yet it is bedded most accurately to the boiler plate and held down by cone-headed bolts. Great attention has been given to the areas of the ports and passages in the cylinder in order to procure satisfactory working under the most trying conditions.

The governor is of the high-speed, spring-weighted, cross-armed type connected to an equilibrium throttle-valve of large area. The valve gear has been most carefully proportioned, the link motion details have large wearing surfaces which are deeply case-hardened. All the bearing brackets for the crank-shaft, countershafts and axle are of great strength; they are each fitted into bored holes in the sides of the firebox shell, which are carried upward and backward for the purpose. Transverse plates, riveted to the boiler shell, connect the side plates together. The gearing used throughout the engine is of best cast steel, the first motion wheels are placed inside the box brackets between the bearings. The fast and slow speed wheels are cast together, and slide in and out of gear on a square shaft, the use of feather keys let into the shaft or keys cut out of the solid material are discarded. A square shaft is a far more satisfactory arrangement.

Strong section steel tee rings are used for the driving and leading wheels. A slip winding drum and 50 yards of strong steel wire rope are provided. A case-hardened ball-and-socket joint on the fore-axle reduces the friction to a minimum, and enables the steering to be effected with facility and certainty. The steerage hand-wheel is placed on the fly-wheel side of the engine, the steersman can see clearly to sight the fly-wheel in line with the pulley of the machine to be driven. It is also the most convenient for steering close to the edge of the road so as to give as much room as possible to passing vehicles.

A continuous action feed-pump is used, the valve boxes, valves, and bonnets are of gunmetal, the passages and pipes are proportioned so as to reduce noise.

The tender has a large storage capacity for coal and water. The sides of the tender are connected to the horn-plates by turned bolts in rimered holes, independently of those which keep the brackets in place. A channel iron drawbar extends across the back of the tender, to which deep straps are welded on each side; by this means the hauling strains are transmitted to the strong horn-plates, and no pull passes through the plates of the tender or tank. A series of holes is provided in the drawbar, so that the draft pins may be moved out of the centre of the bar for turning sharp corners with a long train behind.

G 4

Sliding fire-doors are fitted, as they take up no room in the tender. A deflector plate is provided so as to conform with the Act of Parliament, as far as possible, in having provision for consuming the smoke.

The workmanship throughout is faultless. All the bolts are turned and driven into rimered holes with heavy hand-hammers. No black bolts are used. The machine work and the fitting will bear the strictest investigation. No expense has been spared to produce a perfectly satisfactory engine in every way.

THE DESIGN OF AUTOMOTOR VEHICLE ENGINES.

Writing in the *Engineering Magazine*, Mr. Worby Beaumont says:—During the coming year there will be great activity in connection with the endeavour to make a satisfactory motor-wagon for carrying from two to five tons. For the purposes of an example, let us look at the problem from the steam power point of view. The first requirement is an engine which must be exceedingly economical, if possible more economical of the steam supplied to it than any engine of any kind yet made. Yet the engine must be smaller than any economical engines yet made, and this involves a disregard of adverse experience to the present time as to economy and small engines. Of all the highly efficient engines yet made there is not one suited to the purpose. They have too many parts, and are far too complicated when fitted with reversing gear. They must be most economical when giving out the maximum power, which may not be more than, at the most, 15 minutes at a time, and not one-fifth or, may be in some countries, one-tenth of the whole time of running. Economy at maximum load must be attended with almost equally low consumption at mean load, if not at light load, and the difference between full load and light load cannot be economically effected by throttle valve governing. It is not necessary that the steam consumption shall be equally low for both directions of running, running backwards seldom lasting more than a very small fraction of the forward running time. The reversing arrangement must not, moreover, introduce a form of valve gear which is less efficient than the best possible.

The engine must be capable of running many hours at high speed under the worst conditions as to stresses other than those which necessarily attach to its performance of work, and yet must be very economical at the lower, perhaps half, speed of the periods when it is doing its utmost. With all these essentials the engine itself must be very simple, even if it have not the minimum number of parts, and its manipulation must be of the simplest kind, one lever or handle only, if possible, in addition to a stop valve. Just as a higher type of engine reliable for long periods of running has been developed for electric lighting, so must an engine be evolved which, while answering all the requirements above set forth, will be so trustworthy that the driver of the motor-vehicle may be able to disregard its existence. For many minutes at a time he must be as free to forget that his manipulation of steering and regulating levers depends upon an engine somewhere hidden in his car, as a horse-driver is to forget that obedience to his pull of the reins depends on the heart stowed away inside the horse. The necessity for economy is not, however, primarily the reduction of the cost of fuel to the lowest limit as it is with the electric-lighting engine.

The first necessity in a road-vehicle engine is economy in steam rather than in fuel. In fact, the cost of fuel, even with engines and boilers at present readily available, is no bar to progress in the construction of acceptable motor-vehicles. With a boiler which only generates six or seven pounds of steam per pound of, say, coke, the weight of fuel to be carried per mile would be small with a good engine. It is because the boiler must be of very small dimensions per horse power and because the condenser must be small that the quantity of steam to be generated and subsequently liquefied must be lower than with any small engines yet made. In order to avoid carrying more than a minimum of feed water and of cooling water, the condenser should be capable of liquefying all the steam exhausted when the engine is working its hardest with a full load up a long stiff hill. This maximum capacity of the condenser which must be provided, and its weight, size, and the weight of water to be carried for its use, all alike depend on the efficiency of the engine.

LES POIDS LOURDS.

Report of the Commission.

The following is an excerpt from the paper on this subject read by M. Jentaud before the French Society of Civil Engineers:—

It will be remembered that out of the 15 vehicles entered only 10 were ready to take part in the competition, and that out of these 10 there were three which were prevented by accidents on the way from doing the whole of the stated course. The Commission thinks it best not to give the names of their constructors in the report.

This report is divided into three parts: the general considerations, the account given by the judges of the competition, and the results.

General Considerations.

At the present time in every department the representatives of the people are frightened at the heavy burdens which must be imposed for many years on the budgets of the departments, as well as of the State, by the railways and tramways already made, and those about to be made. However, it is no use refusing to complete the links of our iron roads by a network of lines connecting the various stations.

Struck by the results of the Paris-Bordeaux and Paris-Marseilles lines, the general Councils, as well as the people, hope that automobilism will give them an easy solution of the problem.

This is an interesting question, not only for omnibus companies but also for the War Administration.

Classification of Vehicles.—The Commission established the following classification:—

I.—*Public Transport for Passengers.*

(1) Automotor Vehicles (Steam).

(No. 2.) Scotte omnibus.
(No. 14.) Omnibus by Dion and Bouton.

(Petrol.)

(No. 10.) Panhard and Levassor omnibus.

(2) Vehicles by Bogie Motor.

(No. 13.) Pauline by Dion and Bouton (steam).

(3) Automotor Vehicles Towing Others.

(No. 3.) The Scotte train for passengers (steam).

II.—*Transport for Merchandise.*

(1) Automotor Vehicles.

(No. 8.) Camion by Dietrich & Co (petrol).

(2) Automotor Vehicles Towing Others.

(No. 2.) Scotte train for merchandise (steam).

From this it will be seen that carriages for parcels delivery did not run in the competition. By the professional man it will be seen that a passengers' vehicle could easily be turned into a delivery carriage without having to alter the motor and its transmissions. The Commission regret a scruple, mentioned in the programme, hindered a commercial carriage from taking part in the competition. The interest with which the public attends at the Place d'Armes de Versailles, to follow the evolutions of a carriage from the Grands Magazins du Louvre, which is its regular route every day, makes it to be wished that, in the approaching year, those vehicles will enter for the competition.

Before discussing the merits and the statements made by the Commissioners relative to each vehicle and the cost per ton-kilometre or passenger-kilometre, it is necessary to explain the method of calculation adopted.

From the kilometric statements of the Commissioners we have deduced the average commercial speed, that is to say, that which corresponds to the different capabilities of the vehicle. This average speed corresponds to the number of kilometres capable of being run in a journey of 10 hours, for example. The total weight circulating on every journey, multiplied by the length of the way, gives the number of ton-kilometre which, compared with the total consumption of coke and water, determines the weight of the fuel and the volume of water necessary for the transport of a kilometric ton.

This obtained, in order to obtain the cost it is necessary to add to the outlay for fuel that resulting from the personal expenses, interest, the redeeming of the capital, the cost of maintenance, as well as the cost of repair of the vehicle.

Determinations of the Commercial Speed.—This is the quotient of the number of kilometres gone over by the time taken. From the total time the following must be deducted:—

1. Stoppage at different places for fuel, &c.
2. Stoppage at stations for loading and unloading.
3. Accidents on the way.

Calculation of the Work Done.—The work has been calculated in kilometric tons, by multiplying the average weight expressed in tons by the distance really run, taking into account accidents on the way. The average weight is that of the vehicle carrying half its load.

In dividing the quantity of fuel consumed in six days by the sum of the kilometric tons for six journeys, the average consumption of fuel necessary for a kilometric ton is obtained. An analogous calculation gives the average consumption of water. The consumption of fuel and water necessary for the transport of a kilometric ton of luggage, or for a passenger kilometre, is easily obtained.

Calculation of the Cost.—The expenses must be divided into two groups:—

(1) Those scarcely varying with the greater or lesser use of material, such as the redeeming of the capital, personal salary, fuel for lighting, greasing, and general expenses.

In this category, for one cent. of the capital the cost of repair and maintenance of the material, as well as the special expenses, may be regarded as a fraction of the intensity of the traffic.

(2) Others essentially variable, and dependent on the work effected, are the consumption of fuel and water.

In order to estimate them, after having determined, by right of its commercial average speed, the number of kilometres that the vehicle can run in a journey (of 10 hours), we have calculated how many kilometric tons, corresponding to the following conditions—

(*a*) The vehicle was worked at one-third loaded;
(*b*) The vehicle was worked at two-thirds loaded;
(*c*) The vehicle was fully loaded.

In applying to each of these numbers the coefficients for consumption as it has been stated above, we obtain the necessary quantities of fuel and water; then, applying to the proper costs, the corresponding expenses. To these are added the fixed expenses, being given the total expenses for the day's work.

Lastly, in dividing the total expenses by the number of corresponding kilometric tons, we obtain the price of transport for the kilometric ton, and of the transport of one kilometre for a passenger with or without luggage.

It is necessary to remark that all our calculations and estimations only apply to those vehicles placed in working conditions identical to those which we found during the competition.

(*To be continued.*)

MESSRS. JESSE ELLIS & CO.'S AUTOMOTOR.

We are indebted to the *South Eastern Gazette* for many of the following particulars:—

This vehicle, which Messrs. Jesse Ellis and Co., agricultural engineers, of Maidstone, have just completed, is designed for the expeditious transport of produce by road, and to judge from a series of trials that took place on the London Road, near Maidstone, recently, it is admirably suited for the purpose. This motor-wagon is one that has been specially manufactured for South Africa, and is considerably heavier than those to be constructed for this country. It weighs about five tons, and is of 25 I.H.P. Its form is not unlike that of a street ambulance, the machinery being in the rear. Oil is used, and a journey of some 50 miles or so can be covered before this needs replenishing. The speed varies from three to six or seven miles, the latter being easily attained on ordinary roads. The carrying capacity is about five to six tons. The wagon was entirely under control, easily manipulated, could be steered to a nicety, and started or stopped instantly.

THE GULZOW-FIEDLER ACCUMULATOR.

A secondary cell for which very high efficiency, small weight, and great durability are claimed is the Gulzow-Fiedler, which is being introduced by a company bearing that name and whose offices are at 199, Drummond Street, London, N.W. Much has been attempted in the direction of improving secondary cells in recent years, but the actual progress made has not been very great. Owing, however, to the rapid extension of electric lighting and the large field for electricity as a propelling agent in vehicles and boats, inventors have every inducement to produce a cell which shall combine large capacity with durability and small weight. The problem is admittedly a difficult one, as mechanical considerations have to be governed by chemical ones. It would seem, however, that a considerable advance has been made by the Gulzow-Fiedler Company, and if their cell stands the tests which we are informed are being made there will be a large demand for it, especially for use in motor-vehicles. The cell in question has, it is claimed, not a few important electrical advantages over existing ones. For instance, the charging and discharge can be either slow or rapid as may be desired, and a very rapid discharge does not induce disintegration or buckling; on the contrary, rapid discharging positively improves the plates, and we understand that they actually become denser and more perfect the longer they are used. The plates are formed of a hard lead and are shaped not unlike a warehouse window, but in the rectangular spaces or windows a salmon-coloured composition is forced while in a soft state, but on drying this paste becomes hard and seems to form a kind of stone. Its manufacture is a secret process, but we should say that chromium oxide is, at any rate, one of its ingredients. Mechanically, these plates are very perfect. They can be thrown about or dropped without producing any sign of breakage. After charging, the paste turns quite black and apparently becomes denser, resembling retort carbon. We failed to break a plate which had been used in a cell for some time. Dilute sulphuric acid is the electrolyte. When new the plates require about 30 hours while being formed; after that they can be charged in 10 hours with a current of 1 ampère or in 1 hour with 12 ampères. They can be discharged at any rate up to 12 ampères per square decimetre. Short circuiting does not adversely affect the cells, and there is no rise in temperature of the electrolyte while charging.

The following are the leading particulars of the Gulzow-Fiedler cell:—

Number of plates, 13.
Dimensions of cell, 124 mm. × 165 mm. × 305 mm.
Weight of cell, 28 lbs.
Weight of acid. 6 lbs.
Specific gravity of electrolyte, 1·15.
Maximum charge, 60 ampères.
Maximum discharge for 5 hours, 50 ampères.
Maximum discharge for 8 hours, 35 ampères.

The weight per kilowatt-hour is about 70 lbs., which is certainly a low figure.

Cost of Locomotion in Paris.—In connection with the electric cabs in Paris, the following costs of various methods of locomotion made by the Compagnie Générale are instructive:—

Horse cab, 15 francs 44 cents. per day.
Petrol cab, 13 francs 20 cents. per day.
Electric cab (Kriéger's) 8 francs 13 cents. per day.

There is an economy of 47 per cent. over the horse and 32 per cent. over the oil motor.

Talcine.—We have received from the Dynamo Brush Company, of Finsbury Pavement, London, a sample of a lubricant called *Talcine.* On examination this seems to us to be a compound of ground mica and astaki. It is unquestionably a good lubricant; it is intended for dynamos and motors, and should be invaluable to users of electric motor-vehicles, as in these the motor is apt to get dirty and spark a good deal. The practice of putting oil in the commutator is very detrimental, yet the continual rubbing between two dry metallic surfaces necessitates the use of some suitable preparation such as Talcine; by its use the friction of the brushes is allayed, the efficiency of the machine is increased, sparking stopped, and the commutator assumes the dark burnished skin indicative of careful running. This compound does not deteriorate by clogging the brushes, carbonising, &c.

NAUTICAL AUTOMOBILISM.

"The Nymph."

If the reader can imagine an ordinary river wherry carrying a number of cells under the thwarts and being connected by a short length of pipe to the stern of a small floating body shaped above the waterline like a swan and carrying within it a small electro-motor, the whole thing reminding one of the swan scene in "Lohengrin," he will have a very good idea of the craft on board of which a representative of the Automotor recently had a trial trip at Reading. Although called an "invention" it really is nothing more than a tug attached to a larger craft by a rigid connection. At the same time, for picnic and other pleasure purposes, the idea underlying "The Nymph" design has a good deal to recommend it. Regarded in this light there is undoubtedly a good deal in it. Of course from the naval architect's and shipmaster's point of view it leaves much to be desired. There is nothing that calls for remark in the arrangement of the machinery. The cells are arranged in sections, and by means of a simple switch can be coupled up in certain combinations so as to give full or half-speed ahead or astern, the current going by leads to the motor contained in the body of bird or other fanciful form, such as a mermaid or dolphin, that may be attached to the bow. The motor drives a small two-bladed propeller having stepped blades. As might be expected, there is considerable wave-making disturbance set up, and there is a considerable loss of power. In fact, except for pleasure purposes, the system has no advantage. Steering is effected by reins attached to a bit held in the mouth of the swan; this bit, by simple mechanism, actuates two wire tiller ropes which lead aft to the rudder at the stern of the towed vessel. No doubt a number of these fanciful and strange craft will be seen on the upper reaches of the Thames next summer. It is a curious point with us whether this vessel, really two vessels, is to be considered as one or two vessels. If the latter, then the regulations of the Rule of the Road at sea apply, and the swan or dolphin will have to carry side-lights and a masthead light, and these would have to be attached to the beak and wings respectively. The novel craft is to be seen at Bona's Yard, at Reading.

38-knot Torpedo Boats.

Orders have been placed by the Russian Admiralty with the firm of Hawthorn, Leslie, and Co., of Hebburn-on-Tyne, for two 38-knot torpedo-boats with turbine motors, on the principle invented by the Hon. Charles Parsons, and carried out in his vessel the "Turbinia." Each torpedo-boat will be propelled by 12 screws, three on a shaft. They will be the fastest boats in the world.

Those who were present at the Jubilee Naval Review at Spithead will, says the *Pall Mall Gazette*, remember the mild excitement caused by the appearance of the "Turbinia" amid the fleet. It dashed down the lines and round the great assemblage of warships at phenomenal speed, taking special delight in outpacing that sturdy old stayer, the "Victoria and Albert," from the bridge of which the Prince of Wales watched its antics. Before the review the "Turbinia" made a passage from Cowes to Portsmouth at an estimated speed of 32 knots, and at its trials on the Tyne maintained 32¾ knots. It is lightly constructed as a torpedo-boat, 100 feet in length, and depends for its surprising agility on a new steam turbine—an adaptation of the principle of the water-turbine—attached to each of its three shafts. Each shaft carries three screws, so, in all, the vessel has nine screws to propel it.

[We described this vessel in our last issue.—Ed.]

Explosion of a Boiler.

The following is an excerpt from the official report of the inquiry held under the Boiler Explosions Acts as to the cause of an explosion of a boiler which occurred on board the steamship "Contest" on July 25th, when the vessel was off the Mumbles Head:—

The "Contest" is a screw tug boat of 82 tons gross register tonnage, and is propelled by engines of 50 H.P. The vessel was built in 1883, and last year was bought by the present owners, Messrs. Wedlake, Towers, and Co., Swansea, who have employed her for general towing purposes in the Bristol Channel. The engineer stated that, in accordance with the owners' instructions, it was his practice to examine the boiler both internally and externally every three months. His last examination was made on May 2nd last, when a slight leakage was observed from the overall patch at the bottom of the boiler, which he did not deem of sufficient importance to report to the boiler maker. At 11 a.m. on July 24th last, the vessel left Swansea, "seeking." The following day, at about 9.30 a.m., the engineer was on watch and heard a report, which he described as being like that caused by a gauge glass breaking. On examination, steam was found to be issuing from the bottom of the boiler, and as the supplementary feed and the donkey pump failed to maintain the proper water level, the fires were drawn and the vessel brought to anchor in Swansea Bay. It was then found that a rivet had been blown out at the patch already referred to. The steam gauge at the time of the explosion indicated about 75 lbs. per square inch. The vessel was eventually towed to Swansea, where repairs were effected.

The boiler is of the ordinary cylindrical single-ended marine type, with two plain furnaces. The usual mountings are fitted and the safety valves are loaded to a pressure of 80 lbs. per square inch. The Certificate of Registry of the vessel shows that she was built and engined in Hull by Mr. E. Wailes, in 1883, but no particulars of the boiler are given. Several repairs have been effected during the last three years.

The "Contest" is insured with the United Kingdom Steam Tug Trawlers' Association, North Shields.

The boiler was inspected by Mr. John Smart, acting for the above Society, in October last, before the vessel came into the hands of the present owners. It has also been examined on their behalf by Mr. E. Rickard, the foreman boiler maker of the Ocean Dry Dock Company, Swansea, and periodically by the engineer in charge.

Nature of the Explosion.

One of the rivets which secured the patch at the bottom of the boiler shell was blown out. Through the hole thus left open, which was about ¾ inch in diameter, the steam and water escaped with considerable force.

Cause of the Explosion.

The fractured rivet was not found after the explosion, but as there had been slight leakage at this spot for some time past, it is probable that the rivet was originally defective, either through being overheated, or being fractured during the process of riveting.

General Remarks.

In his observations the Engineer-in-Chief of the Board of Trade says:—

The explosion in this case was not of a very serious nature, and consisted in the blowing out of a rivet from the bottom of the boiler shell. Slight leakage had, at the last examination of the boiler, been observed in the vicinity of this rivet, and it is probable that had this been attended to at that time the defect which subsequently caused the explosion might then have been discovered. Although but little damage was caused by the explosion the vessel was totally disabled, and, under the circumstances, might have been placed in a position of considerable danger.

Inland Navigation in Germany.

No one who studies the underlying causes of German industrial progress can fail to notice the important and rapidly-increasing rôle that is played by the canal and navigable rivers which are being improved and extended year by year, and which carry freights at such low rates that, according to the United States Consul-General at Frankfort, protective economists begin to complain that they render the importation of foreign merchandise altogether too cheap and easy. A few figures will show the enormous development of inland water transportation in Germany during the past 10 or 20 years. Prior to the canalisation of the River Main, from Frankfort to its confluence with the Rhine at Mayence, which was finished in 1886, only small boats ascended the river to this point; and Frankfort had a total river traffic of not more than 150,000 tons, against 930,000 tons of freight received and sent annually by rail, the percentage of each being as 14 to 86 respectively. During the first five years after the river was canalised the water traffic rose to 700,000 tons against 1,400,000 tons by rail—an increase of 467 per cent. by river to 50 per cent. increase by rail. Since then the river traffic has steadily increased year by year to a total of 1,753,799 tons in 1896, to which is to be added 225,253 tons of logs and lumber arriving in the form of rafts from the Upper Main. Similarly the trade of Cologne rose from 200,000 tons in 1876 to 1,000,000 tons in 1896, and the grand aggregate of the German Rhine ports grew from 5,100,000 tons to 16,250,000 tons during the same period. The total length of German canals and inland waterways is 8,700 miles, and important extensions—such as the Oder Canal group and the Elbe Trave Canal—are still in course of construction. The Danube-Oder and Oder-Moldau-Elbe Canals will, when completed, form a continuous waterway nearly 2,000 miles long, and will connect the waters of the Baltic with those of the Black Sea.

M. Tellier, a French naval architect, is building several launches fitted with the De Dion et Bouton oil-motor of 1¼ H.P.; the speed attained is 11 kilometres and the displacement of the boat 180 kilogrammes.

An electric launch of fair speed has recently left the yard of Messrs. Smit and Zoon, of Kinderdijk, Holland. It is 52 feet long, 5 feet 7 inches wide, and 3 feet 11 inches deep It carries under the floor 80 Tudor Planté cells, and from these 8 H.P. is developed, given a speed of 7½ miles an hour, maintainable, without recharging, for 7½ hours. Propulsion is by a single screw.

THE LIQUID FUEL COMPANY'S AUTOMOBILE TRAIN.

This road train was built to run between Cirencester and Fairford, Gloucester, a distance of eight miles, in connection with the Midland and South Western Junction Railway and the Great Western Railway. The train consists of a powerful motor-van capable of carrying 2½ to 3 tons of goods and luggage coupled to a passenger car or omnibus capable of seating 20 passengers inside.

The total length of the train (an illustration of which we shall publish next month) coupled together is 35 feet, and can easily be turned within a radius of 20 feet. The coupling arrangement is made elastic, and there is no unpleasant jerking motion when the train is started suddenly.

The van is 14 feet 3 inches long, 6 feet 3 inches wide, 9 feet 6 inches high, and with 250 cubic feet capacity; it is fitted with double folding doors at the back, and sliding doors at either side for greater convenience in handling goods.

The boiler is the Company's type designed especially for motor-cars, and is a combination of the smoke-tube and water-tube, with 100 square feet of heating surface, and is fitted with a 35 H.P. "Lifu," automatically regulated by the steam pressure in the boiler at 225 lbs. pressure per square inch. The largest part of the boiler is below the body of the van, and that part extending through the body is only 20 inches in diameter, and is lagged with asbestos and covered with teak staves; there is practically no heat in the goods compartment of the van from the boiler.

The engine is a double tandem compound-reversible, designed especially for motor-car purposes, capable of developing 20 I.H.P. working compound, and 35 I.H.P. by letting high-pressure steam into the low-pressure cylinders. The engine is securely fastened underneath the body of the van and power is transmitted to a counter-shaft by means of steel cut bevel gears through a telescopic shaft which allows for the action of the springs and unevenness of the roads; the counter-shaft is fitted with a compensating gear and is securely fastened to a pair of steel reaches, steel pinions are fitted to either end of this counter-shaft which run in large internal cut gears fastened to the spokes of the hind wheels, each of these gears being protected with dust-proof guards. The speed ratio of the engine is 12 to 1; all of the shaft gears run in dust-proof oil cases. The exhaust steam from the engine first passes into an exhaust box, thence through a feed-water heater, condenser, and separator combined, the small quantity of steam not being condensed passes into the funnel where it is superheated and made invisible. There are two pumps for feeding the boiler, one being double acting with reduced speed gear working direct from the engine crank shaft, the other an auxiliary duplex pump placed beneath the driver's seat for feeding the boiler when engine is at rest, or which can be used as a hand pump when the boiler contains no steam.

Two water tanks capable of holding 85 gallons are fitted in the van, one above the platform and one below in front of the driver's seat. This is a sufficient quantity of water for a run of 15 miles over rough country roads; both tanks are filled by means of a steam injector in about six minutes. There are also two fuel tanks, capable of holding 20 gallons each, fitted underneath the body of the van at the extreme rear end and are both filled from outside. These may be worked independently or together, and supply can be changed from one tank to the other without letting the fire out. Indicating dials are fitted to each tank which show the exact quantity of oil at all times. The oil consumption when train is fully loaded is from half to one gallon according to the condition of the roads, and can be bought at prices varying from 3½*d.* to 4*d.* per gallon in London. All pipes are of solid drawn copper tubing and are connected by means of the Company's patent joint which can be repaired in about five to ten minutes if necessary.

The steering is controlled by means of a steel lever or tiller placed in a convenient position for the driver, and is connected to the pivoted axles by suitable steel rods; the vehicle is at all times under the perfect control of the driver.

A powerful steam brake is fitted to the van which is capable of holding the rear wheels fast at full speed.

The train in all respects is built according to the Locomotives on Highways Act of 1896, and to the Local Government Board's Rules and Regulations. The van, unladen (without fuel and water) weighs 1 ton 19 cwt.

The omnibus or passenger car weighs 25 cwt., and is fitted with powerful tramcar type of brake, and is worked by the conductor on the rear platform. The total of the train fully loaded is about eight tons, and will climb grades of 10 per cent. with ease, at the limited speed of six miles per hour. The van may be run singly at the rate of eight miles per hour. and is capable of climbing grades of 20 per cent., fully loaded. We may say that this automobile train was designed by and built under the immediate superintendence of Mr. H. A. House, the Company's manager, who is to be congratulated on having produced an exceedingly workmanlike job.

The Liquid Fuel Engineering Company are at present very busy at their works, East Cowes, Isle of Wight, building tradesmen's vans to carry 1½ to 2 tons, also steam lorries to carry 2½ to 4 tons, for prominent London firms; they are also building a steam wagonette to carry seven people, for a private gentleman.

Two New Chronicles of Automobilism.—If an industry is gauged by the literature it occasions there can be little doubt but that automobilism is going to be a very big one, not only in Great Britain but also in France. In the latter country the industry already supports quite a respectable number of papers, and this number has now been increased by the appearance of *Le Motocycle.* This seems to be a well written and arranged paper; it appears fortnightly. We wish it every success. Another new paper devoted to automobilism is the *Samokat*, which, as might be inferred, hails from Russia. If there is one country more than another suited to automobilism it is Russia with her vast plains and long roads, and absence of local railways. There is to be an exhibition of automotors in St. Petersburg next year, and this will, doubtless, give a fillip.

Acetylene.—Without in any way wishing to hinder a new and promising industry, we would caution readers from using acetylene in motor and cycle lamps, unless they thoroughly understand the nature of the chemical processes involved. In Paris a sad accident has recently occurred in which a bicycle manufacturer and one of his workmen were seriously injured through the explosion of acetylene caused by carelessness and ignorance in handling it. Acetylene should always be thoroughly tested, and the user should be assured that it is perfectly free from moisture. On this subject *The Engineer* remarks:—"Acetylene gas, under a pressure of one atmosphere, does not explode when a spark is applied to it, neither does it explode under two atmospheres when a spark is applied, but under a pressure of three atmospheres there is a sharp explosion, the violence of which increases with the pressure, and we have the law: the rate of decomposition increases with the pressure. The above facts are the result of an examination of acetylene gas described by Professor Mixter in an American scientific monthly. From this investigation it is concluded that when used with care acetylene is no more liable to explosion than illuminating gas, but should such an explosion occur the result would doubtless be more disastrous."

THE NATIONAL CYCLE SHOW.

What is undoubtedly the finest exhibition of cycles ever seen has just been held at the Crystal Palace. Something like 3,000 cycles were on view, while the vast amount of accessories and fittings displayed gives one a faint idea of the magnitude of the industry. It should be explained that all the exhibits were essentially British. As regards cycles little need be said, as there was a rather monotonous sameness about them. The Diamond frame is almost universal, while nine-tenths of the machines were fitted with the old unscientific and dangerous brake operating on the fore wheel by means of a lever under the handle-bar. Why does not some firm introduce a really scientific cycle brake? We saw several very crude things in the way of brakes, nothing worthy of special commendation. As regards gears, the bevel gearing, under various names and guises, seems to be coming into favour, but the chain transmission is still the best gear. One of the most interesting departures in gears was the "cam" gear. On the crank are two cams, upon which are mounted rollers at the ends of connecting rods, one on each side. On each side too, and near the end of the bottom strut, is a lug, to which is attached a swinging bar, at the end of which is a roller which engages in the grooves of cams. As the cams rotate the swinging bar oscillates and transmits the motion through the connecting rods to the rear crank.

The Pedusin frame merits a word for its exceeding lightness, but its appearance is not taking. The Howard gear is a novelty, the fore chain wheel being elliptical in plan, the idea being to obtain a greater turning movement when the foot is at the point of maximum effort. Jockey wheels take up the slack chain, and, we should say, absorb as much power as is gained by the device. Very amusing were many of the descriptions of novelties vouchsafed to the inquirer, especially if the latter were an engineer. Many of the voluble young men at the various stands seemed to entertain the ideas on power and speed such as cyclists usually do, and not a few "inventions" had as their *raison d'être* the obtaining of power or energy by some device or other which, needless to remark, was a kinetic impossibility. The various side shows were well worth a visit. Special lathes and tools for cycle manufacture and repair were exhibited by Herbert (of Coventry), Lloyd and Co. (of Birmingham), Melhuish (of London), and others, all these being distinguished by careful design and finish, and quite up to American models. The Mannesman Tube Company had a grand display of tubes of all kinds, ranging from boiler tubes for warships to the light cycle tube. The quality of the steel used for these tubes is superb; it is as soft as silk and as durable as gold, yet the strongest that can be made. The Standard Weldless Tube Company likewise had an excellent display of tubes and tools. Aluminium is largely being used for cycles, and also for engine castings. The British Aluminium Company are doing a big business in supplying the crank-pit chamfers, &c., to automotor manufacturers. Of the makes of lamps and saddles there was no end, but little variety. Altogether the National Cycle Show Committee is to be congratulated, as are the Crystal Palace authorities, on the success of the exhibition.

The Horse-Power of Automotor Vehicles.—In the *Revue des Transports Parisiens* M. Louis Mallant discusses the question of the power to be given to automotor vehicles. He says it is admitted that the tractive effort upon macadamised roads in good condition is 25 kilos. per ton, and each millimetre per metre of rising gradient augments this by 1 kilo. per ton; similarly each millimetre per metre of falling gradient diminishes the tractive resistance by a like amount. He proposes the following formula:—

$$E = \frac{Pv}{10}(7 \pm 3c)$$

where E is the total I.H.P.,

P the total weight of the vehicle in tons,
v the speed in metres per second,
c the gradient in centimetres per metre.

THE HEADLAND AUTOMOTOR.

We have recently had an opportunity of inspecting the electric automotor vehicle designed by and built to the order of the Headland Patent Electric Storage Company (Limited), of 12, Pall Mall, London, and of which we give an illustration. This vehicle, we may remark, took part in the Lord Mayor's Show—not that it thereby derived any special qualification for so doing, but the fact is noteworthy as it indicates the existence of a progressive spirit on the part of the civic authorities which we trust will eventually result in the Lord Mayor using an automotor State carriage, and no doubt Messrs. Headland will be glad to accommodate his lordship. As will be seen the present vehicle is most substantially constructed and of not unpleasing appearance. In all externals it resembles a rather favourite type of carriage much used in the country. It is mounted much in the same way but the wheels have rubber tyres. It has a seating capacity for four persons and can also carry a quantity of luggage. Its tare weight is 23 cwt. The fore part is made with a hood and there is a light splashboard. The starting, steering, and brake levers are placed close by the driver, who thus has full command over the vehicle. The interesting part of the vehicle is, of course, the motor mechanism. This consists of a 4 B.H.P. series wound motor, placed longitudinally, and its frame is pivoted at one end to the axle, hence any motion in the carrying springs does not affect the running. At the end of the armature spindle is a steel bevel pinion which gears into a bronze bevel wheel, the velocity ratio being 9 to 1. This bronze bevel wheel is mounted on the driving axle, and a differential gear is interposed. The arrangement is very good and compact and should wear well. Current for the motor is derived from a battery of 40 Headland cells which are carried in the body of the carriage or "boot." These cells are arranged in four groups of 10 each, and by a special switch can be arranged four groups in parallel or series, or in two groups in parallel, each with two groups in series. No resistances are used, the various speeds being obtained by the different groupings. The capacity of the battery is 150 ampère hours, and a single charge suffices for a run of about 45 to 50 miles. The charging current is 30 to 40 ampères, and the normal discharge is at the rate of 25 ampères. At the opening of the new Automobile Club this vehicle was much in evidence and was greatly admired. Our representative speaks highly of its smoothness of running and the absence of vibration and noise. It has three speeds, viz., 3, 7, and 15 miles per hour. We understand that the Headland Company are very busy, and are supplying their batteries to a car for the Duke of Orleans, and also to some electric barges being built for Messrs. Lever Brothers, of Port Sunlight, the well-known soapmakers.

Naval Automobilism.—Two lectures on the British Navy, illustrated with lantern slides, and adapted to a juvenile audience, will be given in the East Conference Hall of the Imperial Institute by Captain S. Eardley-Wilmot, R.N., on January 15th and 22nd, at 3 p.m.

DOINGS OF PUBLIC COMPANIES.

ALLOTMENT letters were posted on December 1st to the subscribers to G. R. Blot and Co. (Limited).

STIRLING'S Motor-Cars (Limited) is the title of a Scotch Company formed to take over the business of Messrs. J. and C. Stirling, of Hamilton, N.B.

MR. CHARLES OSBORN has resigned the secretaryship of the Horseless Carriage Company (Limited) on his appointment to a similar office in the Amalgamated Tyres Company (Limited).

MR. T. H. PARKER (son of Mr. Thomas Parker, J.P., of Wolverhampton) has sold his motor-car invention, and the five or six patents connected therewith, to a new company just registered under the title of "The Electric Street Car Manufacturing Syndicate." The capital of the Company is £25,000, which has been privately and locally subscribed.

IN the action by the Great Horseless Carriage Company's shareholders for the recovery of their money, being conducted by Mr. Hunter, circulars and counter-circulars in regard to the liability for costs have recently been scattered broadcast amongst those most intimately concerned. We should not personally like to give an opinion upon the ultimate legal liability of any of the litigants, but due weight should certainly be accorded to the very strong expressions of opinion and statements contained in Mr. Hunter's communications.

THE accounts of the Britannia Motor Company have been issued in anticipation of the general meeting to be held to-day, December 15th. They hardly present a satisfactory state of affairs, and we shall look with some curiosity to see what explanation can be given to place upon them a better construction than at present they bear. We notice that the *Star* is still pounding away as to the distribution of the item of commission which was paid to a Mr. Davis in connection with the sale of the Britannia Company's patents to the British Motor Syndicate. No doubt at the meeting reference will be made to this matter, which upon the face of it certainly requires clearing up.

THE statutory meeting of the Blackpool Motor-Car Company was held on November 27th, at the Victoria Hotel, Manchester, when the chairman reported that the board were fully satisfied with the public support given to their undertaking during the past season, and that they had been successful in letting out the whole of their cars for the winter season at such prices that a fair profit would be realised. They have under consideration the placing of further orders for larger cars for next season to carry more passengers than those at present in use, embracing all the latest improvements. It was also remarked that the directors hope at the end of the financial year to declare a good dividend.

THE report of the directors presented to the shareholders of Richard Hornsby and Sons, at the annual general meeting held a few days back, states that the balance-sheet shows a profit on the year's working of £2,595. This is after making reserve for doubtful debts amounting to £4,000, and after payment of debenture and other interest amounting to £5,703. The directors regret that they are unable to recommend that any dividends be paid, the balance to the debit of profit and loss being £8,189. During the past year 5 per cent. debentures amounting to £33,450 have fallen due, and have been renewed at 4½ per cent. interest.

Humber and Co.

AT the third ordinary general meeting of the shareholders in Humber and Co. (Limited), held on November 19th at the Cannon Street Hotel, under the presidency of Mr. A. R. Marten, Chairman of the Company, Mr. Martin D. Rucker, during his speech as managing director, said there was a matter he should like to touch upon. He did not like the words horseless carriage or motor car, but the directors felt that there would assuredly be a demand for these carriages here, and there was a very large and greatly increasing demand on the Continent. They had been inundated with letters from people asking whether they intended to go into the motor-car business, and he might state that they had been at work quietly at this for the past two years. They had not, however, put anything upon the market because they did not feel that the time was ripe, and they did not feel that they had got an engine which they would like to call by the name of Humber; in fact, they were not going to run any risk of failure at the start. (Hear, hear.) They felt they had now an engine which was superior to anything else which had been brought out; it had not been brought out yet, but they had been trying it for some considerable time past and they believed they had an engine that would supersede all others and make a tremendous trade for the Company. The directors were arranging to set apart a special department for this work, and he thought they would be exceedingly busy. He also believed it would bring very large profits to the Company; at any rate, for some time to come those who were seeking such carriages would be willing to pay any price for the best article. He had been a good deal in Paris lately, going thoroughly into this question, and there he heard of a most extraordinary result. One machine, which cost 6,000 francs to build, was sold originally for 6,000 francs. It was run for 3,000 miles, and then sold for 8,000 francs. It was afterwards bought by an agent for 10,000 francs, and sold the day he was there for 12,000 francs. That would give shareholders an idea of the demand which existed for such vehicles in France. He thought that was all he had to say with regard to the future of the business, but he might add that the directors believed they would be able to do as good if not a better trade in cycles than they had done before, and, in addition to this, they believed they were starting on a very large business in motor-cars.

London Electric Omnibus Company.

A MEETING of the shareholders of the London Electric Omnibus Company (Limited), convened by Mr. William Marshall, the late Deputy-Chairman of the Company, was held on November 25th at the Cannon Street Hotel, E.C., to consider the present position of the Company. The following was the circular sent to the shareholders:—

November 22nd, 1897.

To the Shareholders of the London Electric Omnibus Co. (Ltd.).

GENTLEMEN,—As late Deputy-Chairman of the above Company, I think it my duty to call your attention to the deplorable condition into which the Company has fallen owing to the incompetency of the management.

Your Company has now been formed nearly two years, and in the prospectus you were promised that 125 omnibuses would immediately be placed upon the streets. The Company took over one bus from me, and although the directors, I am informed, have spent something like £25,000, beyond this there is not a single omnibus yet ready to start running.

I have myself invested about £28,000 in cash in the undertaking, and, having influenced others in taking up shares, I am anxious that, before it is too late, the shareholders should take some steps to remedy the present unsatisfactory condition of the Company.

Under these circumstances I request your kind attendance at a meeting of shareholders to be held at the Cannon Street Hotel, on Friday next, November 26th, at 3 o'clock, when you will have an opportunity of judging for yourselves as to the requirements necessary for the future.—I have the honour to be, gentlemen, your obedient servant, WM. MARSHALL.

Care of Messrs. Haydon and Haydon, 16, Union Court, Old Broad Street, E.C.

MR. E. KIMBER presided, and explained that the directors had not called the regular meeting, which ought to have been called before this, to place before the shareholders the Company's present position. Although the circular issued to the shareholders by Mr. Marshall revealed an unsatisfactory state of things, the Company had in it the elements of great success; but, so far, nothing had been accomplished, although the prospectus was issued as long ago as May, 1896. The object of their meeting, therefore, was to give life to the undertaking, to preserve their property, and to place the Company on a better footing. The chairman then referred to various statements in the prospectus which he stated had not been fulfilled.

MR. MARSHALL stated that, according to the prospectus, the directors promised that 125 electric omnibuses were to be immediately placed upon the streets, but so far not a single bus was running. The directors, shortly after taking office, voted themselves £3,000 a year, with a bonus on the profits, and had also appointed Mr. Ward as engineer, at a salary of £1,200 a year. In their circular of August 24th the directors stated that the prospects of the Company were better than heretofore, and that they were buying an interest in the Solar accumulator, which had not been sufficiently tested. He believed the directors did not hold any more than their qualifications. Under the circumstances, he thought a committee of investigation should be appointed. He had heard that the London General Omnibus Company had entered into a contract to put 400 electric omnibuses on the streets, and therefore they were far behind that Company.

After some discussion, a resolution was passed appointing a committee, consisting of Messrs. Ware, Flaxman Haydon, J. E. Condiet, Edmund Kimber, and Colonol Turnbull, to investigate the affairs of the Company.

[The reference to the London General Omnibus Company having ordered 400 electric omnibuses is quite incorrect. Although we understand the directorate is very carefully watching the automotor movement, and is ready at any moment to run motor omnibuses when they consider they can do so with advantage, up to the present they have made no arrangements whatever of a practical nature.—Ed.]

British Motor Syndicate.

The ordinary general meeting of the British Motor Syndicate (Limited), was held on November 18th, at the Motor Mills, Coventry, under the presidency of Mr. Harry J. Lawson. In addition to transacting the ordinary business the shareholders were invited to consider a scheme involving the issue of debentures and preference shares, with a view to taking over the Great Horseless Carriage Company and its assets. About 40 shareholders attended.

The Secretary (Mr. C. Jarrott) read the notice convening the meeting.

The report was taken as read.

The Chairman, during his remarks, said:—To build such cars as you see about the streets, working as hard as we could, would take three or four months, and then it could only be done by working upon a system of interchangeable parts. At the present moment the motor-car industry, both here and in France, is not being carried on on a system that produces most profit; it is being done largely in half-dozens and dozens of cars, so that if you lose one piece you find you cannot get another to fit the machine. I hope that the time is approaching in the manufacture of motor-cars when we shall be able to get the work done under a system which will enable us to turn out any quantity, and at a popular price. Everybody said the coming motor traffic must be worth millions in time, and if it is quicker, cheaper, and altogether better, of course the argument is all on one side. Its success can only be a question of time. We are making as much progress as we possibly can, and before long we shall have cars that will suit the rank and file of the population. I have had a car in daily use for going to and from London for nine months, and the average daily cost has been 1*s.* If it had been working all day it would have cost 1*s.* 6*d.* or 2*s.* probably; but the average cost to me has been 1*s.* a day, using it as I would an ordinary carriage or brougham. I find, on reference to "Whitaker," that there was in 1895 £1,001,110,221 invested in railways, and over £80,000,000 in receipts, while in tramways there is over £10,000,000 invested; but we say that, except for long distances, such as London to Brighton, Edinburgh, or Glasgow, for the average wants of the greatest number we can do better than the railway. The cars will very shortly be in regular use for passengers at fixed fares—in fact, they are already in some towns. They are charging 6*d.* for a four-mile journey at Hamilton, in Scotland, and they are also in regular use by the Blackpool Company. The applications for cars are overwhelming, and they cannot make the cars for that sort of traffic fast enough.

Referring to the accounts the Chairman said:—On one side of the profit and loss account you see an entry of 290,000 shares, and on the other side is shown only an issue of 250,000, and about that I would point out that the 290,000 shares do not mean British motor shares, but they relate to several dealings we have had. In forming syndicates and companies—and a great number more will have to be formed before the country is half supplied—we have to take cash and shares according to the terms arranged. A question has been raised with regard to the dividends paid. These dividends were paid in May and July; but, of course, the more recent shareholders have not participated in them—they were paid before they came into the Company. I do not think it is unreasonable, seeing what sort of a year it has been, and that it would have been sheer folly to have started a fresh company during the present year, that we have no distribution at the present time. Everything in cycles and motors has been at its very lowest, and being Jubilee year there has not been anything like the usual demand for shares generally, quite apart from our kind of share. The gross profits have been £446,285. Of course, part of that is in cash, but a large portion is promotion profit. Then it will be seen that the cost of patents amounted to an enormous sum. Well, that is our whole existence; the whole reason of our being here to-day is that we own inventions and motor patents, and intend to farm patents and exploit patents. No doubt you will have seen in the papers that the Post Office authorities are trying the motor-car as a test. We sent our van to the General Post Office, and they rather smiled incredulously when we said what it would do. They gave us a list of times and places where we had to be to take the mails, and sometimes we picked up mail bags to the weight of about 11 cwt. or 12 cwt. at tha time. In all kinds of weather for weeks that van has been driven, and has kept much more punctual time than has been done by the horse. I do not think a severer test could have been given us. Having satisfied the Post Office authorities of its utility for short distances, we were asked to test it for longer journeys, and it was used for Staines, Richmond, and all that district, while now they are about trying it for the journey from London to Brighton, to Bedford, and other long distances. Well, we know that with regard to long distances they have no possible chance of competing with us with horses; for we can go at almost any speed—as fast as the law will allow us. In France the motor-car has had a long list of successes, and I may tell you that this Company owns all the leading patents that are in use there. The Panhard Company has arranged to turn out 70 motor-cars a month, and, as you know, it is working under our patents. With regard to the Coventry Motor Company, Mr. Turrell, the manager, has made improvement after improvement during this year, and he expects to perfect by the end of the year, or say the end of January, a motor-car which any lady or gentleman can be trusted with and can easily manage, and that one invention will be a great help to us in the motor-car industry, for it will be on the most simple and marketable lines. Then, mention has been made as to the shares issued at a premium. Those shares were principally issued to the vendors, that is to say, to myself and those gentlemen who were acting with me—inventors and patentees. A large portion of this was never taken by us, although it belonged to us, but was left in the coffers of the Company, and has been spent in the development of the industry. But for that the Company would not have been able to have done what it has. I have a large holding in this Company, and would do almost anything for it, and it was because of my large holding that I was anxious to see that the Company had money with which it might obtain advantages by purchasing other inventions which were offered. It is impossible to say how great the results of this Syndicate's work is going to be. I can only say I have the fullest confidence in it, and every penny I can obtain I shall put into the development of the motor industry. I should mention that we are having negotiations from abroad for light railways to be laid down on our lines, and we have every hope that the negotiations will have a satisfactory result. I now beg to move the adoption of the report and accounts.

Mr. James Bradshaw seconded the motion.

Mr. Gurner, Mr. Spain, and other shareholders put questions upon the accounts, and received explanations from Mr. Van Praagh (the solicitor), after which the motion was put to the meeting, and carried.

Mr. Van Praagh explained at length the consideration which had induced the directors to bring forward the suggested acquisition of the Great Horseless Carriage Company, and the issue of debentures and preference shares for effecting that object. After considerable negotiations, an understanding was arrived at provisionally, but since then certain variations had been suggested, which it was hoped would be satisfactorily arranged. In order to carry out the bargain contemplated it was necessary for the Board to issue the 100,000 shares, the balance of capital remaining, and another 100,000 shares which would be supplied by Mr. Lawson, and issued as preference shares to the shareholders of the Great Horseless Carriage Company in exchange for part of their present holdings. In addition to that the Board would require to issue debentures. Mr. Lawson was willing to come to the rescue, and to give up 100,000 and to take £50,000 out of the issue of £100,000 debentures, to bear interest at the rate of 4 per cent. The shares he would give up, together with those the Company had, would be converted into preference shares, and bear interest at the rate of 5 per cent. As he (Mr. Van Praagh) acted as solicitor to Mr. Lawson, the Syndicate would be represented in this matter by Messrs. Ashurst, Morris, Crisp, and Co., who were represented at that meeting by Mr. Stephenson. He would, therefore, ask that gentleman to read the agreement made between Mr. Lawson and the Syndicate.

The agreement having been read, Mr. Thomas Child, who had taken the chair on its being temporarily vacated by Mr. Lawson (on account of his being concerned in the transaction), formally proposed the resolution approving the agreement, which was carried with one dissentient. A resolution was also agreed to empowering the directors to issue such debentures and preference shares as they might find necessary for the purpose of taking over the Great Horseless Carriage Company's undertaking as proposed.

An extraordinary general meeting was then held for the purpose of making certain alterations in the articles of association; but it was explained that these were largely to meet the requirements of the Stock Exchange Committee. The motion was unanimously agreed to.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

	Capital.
Bradford and District Cycle and Motor-Car Traders' Association, Ld. (Unicorn Passage, Ivegate, Bradford)	£500
E. C. Clarke, Ld. (1, Friargate, Derby)	7,000
Electric Street Car Manufacturing Syndicate, Ld.	25,000
Indian Cycle and General Engineering Co., Ld. (2, Gresham Buildings, Basinghall Street, E.C.)	10,000
Joseph Lucas, Ld. (Great King Street, Birmingham) ..	225,000
Motor-Car Emporium, Ld.	5,000
Power and Traction, Ld. (79, Palace Chambers, Westminster)	10,000
Samuel Weston, Ld. (Barclay's Bank Chambers, Terminus Road, Eastbourne)	52,000
Wheel Manufacturing Co., Ld.	90,000
White and Middleton Gas Engine Co., Ld.	200,000

LAW REPORTS.

The Great Horseless Carriage Company and the British Motor Syndicate.

On November 25th, in the action of Henry Charles Le Hersant, suing on behalf of himself and all other shareholders of the defendant company, plaintiff, *v.* the Great Horseless Carriage Company (Limited), Mr. Warrington, Q.C., asked Mr. Justice Kekewich, sitting in the Chancery Division of the High Court of Justice, to grant an injunction restraining, until the trial of the action or further order, the defendants, their directors, managers, or officials from executing or in any way proceeding with the negotiations for a proposed agreement between the defendants and the British Motor Syndicate (Limited), whereby the assets and undertaking of the defendants were proposed to be transferred to the said Syndicate, and from in any way transferring or parting with to the Syndicate the assets of the defendants.

In stating the case for the plaintiff, Mr. Warrington said that the action was brought to prevent the carrying out of what he ventured to characterise as an outrageous fraud upon the shareholders of the defendant Company on the part of what he understood was practically only one director, viz., Mr. Harry J. Lawson. The articles of the Company no doubt gave power to the directors, and in certain events a single director, amongst other things, to sell the whole of the assets of the Company for shares in another company. The only asset of the Company of value, he understood, was £50,000 cash in the bank, the proceeds of the subscriptions of some 90 persons who had applied for shares to the extent of about £34,000, but had all taken proceedings against the Company and the directors with a view of recovering against the Company the money they had paid for such shares, and against the directors for damages for misrepresentation. The present plaintiff was one of these persons in respect of fully paid-up shares. Lawson, who seemed to have the control of the Company, had, according to the affidavits, a very large claim, which he had settled by taking debentures in a company called the British Motor Syndicate (Limited), and it was this agreement it was proposed to prevent being carried out, as one of the class of cases coming within a well-known rule. As he had said, there had been no meeting of the defendant Company; but Lawson, acting solely in the matter, proposed to assign its assets to the British Motor Syndicate, of which he was one of the directors and held the bulk of the shares, his brother-in-law (Thomas Robinson) being a second director, and a Mr. Child the third. It was to take over the patents of the Horseless undertaking, and the effect of the agreement, if not restrained, would give Lawson the power of receiving up to 750,000 shares, which were of the nominal amount of £1 each, but he (the learned counsel) understood had been issued at £8 each, and in this arrangement also to get control of the defendant Company's assets of £50,000, the Motor Syndicate arrangement being, it was suggested, a mere blind, in effect, to enable Lawson, for his own benefit, to obtain that £50,000.

Without calling on Mr. Warmington, Q.C. (who with Sir Edward Clarke, Q.C., appeared for the defendant Company), Mr. Justice Kekewich refused the application. If he were satisfied that the case was one of fraud he should not, he said, hesitate to act in restraint; but he conceived it had not been made out, even to the extent of constituting a *primâ-facie* case, justifying the course he was asked to take. It might be true that Mr. Lawson both had the control of the Company and a great interest in the Syndicate, and was entitled to receive a large sum under it; but he saw no reason in that for concluding that he would not exercise his powers reasonably and honestly for the benefit of the defendant Company, which, he gathered, was not able to carry out its designs without the aid of some stronger company. As, to his mind, there was not sufficient proof of Mr. Lawson's desire to act other than honestly he declined to interfere at this stage, and refused the motion, the costs to be those of the defendants in any event.

Mr. Warmington said he desired to say the defendants did not admit much of what had been alleged, nor was it true to say that Mr. Lawson was the only director.

Bankruptcy Court.

On November 23rd, in the High Court of Bankruptcy, a receiving order was made against Charles Nigel Stewart, 39, Victoria Street, Westminster.

At a meeting of the New-Mayne Electric Rudder Motor Syndicate, held at Palace Chambers, Westminster, on November 13th, a resolution was passed winding up the Company voluntarily, as it could not, by reason of its liabilities, continue business. Mr. D. F. Basden, of 3 , St. Swithin's Lane, E.C., was appointed liquidator.

On November 18th Mr. Registrar Hope presided at a sitting for the public examination of Sydney Hersco, financial agent, &c., of 14 and 15, Coleman Street, E.C., who failed last August, with total liabilities, £14,996, and assets valued at sufficient to provide a surplus of £2,417. Under examination the debtor said he commenced business as a financial agent at Palmerston Buildings in 1882. Since then he had assisted in the promotion of various public companies. During the last two years he had assisted in the promotion of the Tavernier Motor Syndicate (Limited), the Armstrong-Dove Motor Syndicate (Limited), &c. Lack of capital to work a slate quarry and a fire-clay mining works had contributed to his failure. The examination was adjourned for a cash account to be filed by the debtor.

In the matter of New and Mayne (Limited), Mr. Registrar Hood has sanctioned the recently-approved scheme of arrangement being submitted to the creditors and contributories of the Company. For the purpose of the necessary resolutions, the liquidator, Mr. D. F. Basden, has convened meetings of the creditors and contributories to be held to-day (December 15th), at the Westminster Palace Hotel. It is proposed to incorporate a new Company, under the title of the Engine Patents Development Company (Limited), with a nominal capital of £3,750, divided into 75,000 shares of one shilling each: the new directors to be Mr. Reuben Hunt, Mr. William Shrimpton, and Mr. Anthony G. New. Working capital is to be raised by the issue of "A" debentures not exceeding £10,000, and "B" debentures are to be issued to Mr. M. D. Rucker in part redemption of

H 4

his existing debentures in New and Mayne (Limited), the balance of his debt being satisfied by deferred debenture stock ranking *pari passu* with deferred debenture stock to be issued to all the other creditors of New and Mayne (Limited).

On November 19th, before Mr. Registrar Linklater, William Marshall, mining and electrical engineer, 16, Tokenhouse Yard, E.C., attended for public examination upon accounts showing gross liabilities £15,390, of which £6,701 are unsecured, and assets valued at sufficient to yield a surplus of £54,560. He stated, in reply to the Official Receiver, that from 1869 to 1894 he was in Australia and South America acting as a consulting engineer. He returned to England in August, 1894, with £1,500 capital, and started business as a mining and electrical engineer at Tokenhouse Yard. In the course of that business he financed the inventors of certain electrical patents, and in that way expended between £6,000 and £7,000. Then in May, 1896, he floated the London Electrical Omnibus Company (Limited), with a capital of £250,000, to acquire the plant and patents. As vendor, he was to receive £20,000 in cash and £80,000 in shares. The initial expenses amounted to about £14,000. The public subscription did not come up to expectation, and eventually he returned £13,816 of the cash consideration, and took up the unsubscribed balance of 27,633 shares. He had returned the value of his shares at par in the statement of affairs, but they would not be worth that amount until the omnibuses started running. Witness attributed his appearance at the Court to loss in connection with the City of Mexico Tramways, and his inability to immediately realise his shares in the London Electrical Omnibus Company.

At the conclusion of the examination the Registrar pointed out to the debtor that his accounts showed a surplus because he had returned his Company shares at their face value, and asked whether he wished to amend the accounts.

In reply, the debtor said he would stick to his guns, as he confidently expected to realise the full amount in due course of time.

The debtor was then allowed to pass.

A Motor-Cab Without a Lamp.—Thomas Nugent was summoned for driving a motor-cab without a light on the north side of Clapham Common on the night of the 12th ult. P.C. 400 W said that the defendant was in charge of one motor-cab, and attached to it was another motor-cab. When the cab stopped the electric light flew into the lamps, but the moment the vehicle moved the light went out. The cab was going at a very slow rate. The defendant said he had been sent to Kingston to fetch a cab that had broken down, and the road was so bad that the electricity in his cab became exhausted. Mr. Marsham inflicted a fine of 10*s.* and 2*s.* costs.

A Drunken Motor Cabby.—Leonard Carter, 30, was charged before Mr. Hannay, at Marlborough Street Police Court, on November 16th, with being drunk while in charge of a motor-cab. Constable 390 C deposed that at about 10 o'clock on Monday night he saw the prisoner drive a motor-cab out of Regent Street into Piccadilly Circus. He appeared at first to be going straight across the circus, but suddenly turned round, with the result that he collided with a four-wheeled cab, cutting the horse attached to it on the head and damaging also the motor. Finding that Carter was drunk witness took him into custody. In defence, the prisoner said he did not consider himself drunk when the accident occurred. The traffic caused him to turn and a cab at the same moment turned, causing the collision. Mr. Hannay said the inspector at the station must have thought the accused drunk as he would not have taken the charge. As nothing was known against the prisoner he would only be fined 5*s.* as a caution.

Liverpool Policemanism.—At Liverpool, on the 21st ult., Inspector Breeze summoned James Urmson for using a motor-vehicle principally for the purpose of displaying advertisements on the 16th ult. in Lime Street. Charles Taylor and Levi Nutter were summoned for aiding and abetting. Mr. Cripps prosecuted and Mr. Lynskey appeared to defend. It was stated that on the date mentioned Inspector Breeze saw the vehicle standing opposite 30, Lime Street, the premises occupied by Messrs. Joseph Crosfield and Sons, Soapmakers, Warrington. He asked Urmson what the vehicle was intended for, and the reply was "advertising round the town." Inside the vehicle there were small packets like samples and a quantity of handbills. For the defence, Urmson and the others, as well as Mr. J. F. Jones, Liverpool manager for the firm, were examined. They stated that the vehicle was used entirely for trade purposes—delivering goods ordered by their customers in different parts of the town. With the exception of the lettering on the exterior of the cart there was no other advertising purpose. The bench upon this dismissed the case. The car was drawn up in the police courtyard.

A Policeman Tries to Drive an Electric Cab.—Richard Thompson, 46, an electric cabdriver, of Blackfriars, was charged on December 10th, at Clerkenwell Police-court with being drunk while in charge of his vehicle in Gray's Inn Road. P.C. 120 E said shortly after midnight on the 3rd inst. he saw the defendant driving an electric vehicle along Gray's Inn Road. Thompson was leaning over very much on his cab seat, and nearly drove the vehicle into a refuge in the middle of the roadway. The defendant did not stop when first called upon by the officer, but after driving 200 yards brought the vehicle to a standstill. He refused to get down from his seat, and had to be forcibly taken down by the witness and another constable. The doctor at the station said defendant was drunk. Mr. Edmunds, who appeared for the defence: Did you get on to the cab? Witness: No; the other officer got on the seat of the cab and proceeded to drive. Mr. Edmunds: Did he drive the cab into a wall? Witness: No; he drove it on to the pavement (laughter). Mr. Edmunds: Is it not a fact that your brother officer soon had enough of electric cab driving, and did he not leave the vehicle in the middle of the roadway for anyone to take? Witness: He did leave it in the roadway (laughter). P.C. 444 E. said he attempted to drive the cab, but after colliding with the kerb got down. Mr. Edmunds said the defendant bad an irreproachable character. He had been a cabdriver for 26 years, and during that time had only been once before a magistrate. He was then fined 6*d.* He occasionally suffered internal pains, and when he was stopped by the officers he had a seizure. In consequence of the damage done to the vehicle by the constable who attempted to drive it, the defendant had had to pay £1 2*s.* 6*d.* for repairs. Ultimately the defendant was bound over to be of good behaviour for three months.

The National Traction-Engine Owners' and Users' Association.—The fourth annual meeting of this association was held on the 8th inst. at the Agricultural Hall, Mr. E. B. Chittenden presiding. The annual report, as read by the secretary, Mr. H. R. Summers, stated that the financial support received was still altogether inadequate, though many new members had been enrolled. The committee were of opinion that the association had proved that the present restrictions on road locomotive traffic could be removed by energetic combination. There was no doubt that the use of heavy steam road locomotion was increasing and attracting a large share of public attention. It was, therefore, more than ever necessary that engine-owners should combine together to get whatever improvements were possible. The committee looked forward to some progress being made in the attainment of the association's demands during the next Session of Parliament, if the owners would give their support. On the motion of the chairman, seconded by Mr. Fenton, C.C. (Devon), the report and accounts were adopted, and the general council re-elected. Mr. Griffith Boscawen, M.P., was re-elected president of the association. On the motion of Mr. H. Westley (Cambridge), seconded by Mr. W. Arnold (East Peckham), the following resolution was adopted:—"That this meeting urges Her Majesty's Government to consider the important question of agricultural steam road locomotion and to give facilities for passing into law a Bill to provide uniform regulations and greater legislative freedom for traction-engines."

NOTES OF THE MONTH.

A ROYAL WARRANT has been granted to the Electrical Power Storage Company (Limited) appointing them makers of electrical secondary batteries to Her Majesty.

THE Chelsea Vestry has passed the resolution for the surveyor to obtain full information as to the cost of motor-vans. It is proposed to employ 12 cars for the home district and three for Kensal Town.

IT is stated that the Hon. C. A. Parsons is about to construct at Newcastle a vessel of the torpedo-boat destroyer type, which he estimates will be capable of easily steaming from 36 to 40 knots an hour.

WE learn from the *Beckenham Chronicle* that the local authority has decided to purchase a motor dust-cart. We feel sure that the enterprising officials will find this investment a source of economy to the ratepayers.

GLASGOW has at length adopted the automotor vehicle, and the magistrates have licensed several "Stirling" automotor vehicles to ply for hire. Trials carried out in the presence of the municipal authorities have been very successful.

WE trust that the owners of the motor-car so unwarrantably interfered with by the Liverpool police will take steps to bring the conduct of the policemen concerned to the notice of the Home Secretary, with a view to getting them punished.

A CONTRACT for a number of light locomotives for Egypt has been secured by Messrs. W. G. Bagnall (Limited), Castle Engine Works, Stafford; and the Oldbury Railway Carriage and Wagon Company (Limited), near Birmingham, have also received from the same quarters an order for 200 wagons.

A NEW illustrated weekly paper is to be published at Manchester, with the title of the *Mechanical Engineer*, the price being 6*d*. Mr. William H. Fowler, Wh.Sc., M.I.M.E., A.M.I.C.E., &c., is the editor, and the Scientific Publishing Company, of Hodson's Court, Corporation Street, Manchester, are the proprietors.

A MOTOR-CAR company for Gourock is in process of being floated. In the event of the tramways company and the commissioners failing to arrive at an agreement with reference to the repairing of the rails and roadway at the end of the present lease, which occurs within a few months, the motors are intended to take the places of the ordinary cars between Cardwell Bay and Ashton.

SAYS a recent issue of *Vanity Fair*:—It may not be generally known that the motor-cabs are almost useless in the crowded thoroughfares of the City or anywhere where there is much traffic, because the police—of their own accord or by order of the higher authorities—have a profound distrust of their going faster than a walk or passing any vehicle. As they can be pulled up quicker than the tenderest-mouthed horse, this is absurd. How great is Red Tape, and it shall prevail!

WRITING to *The Times* from Philadelphia, Mr. A. F. Yarrow gives the following particulars of the hours worked at the largest shipyard in America—that of Messrs. Cramp, and in the largest locomotive factory in the world—that of the Baldwin Company. At the former yard, the hours are from 7 a.m. to 12 in the morning, and from 12.45 to 6 p.m. in the evening, whilst on Saturdays work is knocked off at 4.30 in the afternoon. At the Baldwin Works the hours are 7 a.m. to 12 in the morning, and 1 to 6 in the afternoon.

THE contract for the electric lighting of the Dublin Cycle, Tyre, and Motor-Car Exhibition, to be held in January, has been secured by Messrs. Tuck and Co. (Limited). The installation will comprise engines, dynamos, 30 arc lamps, and 1,000 incandescents. The same firm is putting down an installation at the Banagher Distillery, where there will be an engine and dynamo and 300 lamps (incandescents and arcs); and at the Drogheda Steam Laundry they are also putting in engines, dynamos, and boilers for arc and incandescent lighting.

AT the last meeting of the Aberdeen Links and Parks Committee a report was read on negotiations for a motor-car service from the centre of the city to the Duthie Park and the Bathing Station. A letter was read from Messrs. J. and C. Stirling, Hamilton, who run cars from Glasgow to Dumbarton, stating that they would put a service of cars on the routes without asking the Council to purchase them. It was decided to ask them for a specific offer. A drawing by a London firm was submitted of a steam motor-bus to cost £700, but the matter was deferred pending arrangements with Messrs. Stirling.

AN order has been lately issued by the Local Government Board, varying the provisions of Sub-section (4) of Section 28 of the Highways and Locomotives (Amendment) Act, 1878, so that, subject to the conditions specified in the Order, a locomotive may be used on a highway if the driving wheels, instead of being smooth-soled or shod with cross-bars, are shod with wooden blocks. It may not be generally known that in certain parts of Lancashire, local authorities have long since permitted the use of traction-engine wheels shod with wooden blocks, which have been found most suitable for roads paved with granite setts.

ACCORDING to an evening paper, a gentleman conceived the brilliant idea of riding all the way from Oxford Street to Hampstead in a motor-cab; but after the vehicle had proceeded a few hundred yards it slowed and stopped. "The electric power," said the Jehu, "had all gone." So the unsuspecting fare alighted and proceeded on his way. Looking back, he saw that motorious cab merrily plying for hire towards Oxford Street again. Even a horse-cabman, as we must call the class now, could not have dodged the long fare better than that. It is sad to think that the motor-cab should be the cause of so much aberration from the strict path of moral duty.

IT is stated that, in addition to the creation of a large number of additional cab licenses in Leeds, the Hackney Carriages Committee are likely to sanction almost immediately the introduction of motor-cars to ply the streets for public hire. The scheme, it is said, has originated locally. The first public move, however, is directed from London. The chairman of the Hackney Carriages Committee has received from a London company a letter asking for permission to run one motor-cab in the streets, for the benefit, it is understood, of the gentlemen who contemplate the formation of a local company. It is probable that the motor-cab will arrive in Leeds within the next few days.

THE accumulator system at Ostend has been adopted for tramway traction, each car being fitted with 12 cases of nine Laurent-Cély cells each, which have a capacity of 140 ampère hours, and can give a discharge of 50 amperes. Charging takes from three-quarters to two hours. The cars weigh 7½ tons each, batteries excluded, and can accommodate 50 passengers. The motors, of which there are two to each car, are of 18-kilowatt capacity, and were supplied by the Westinghouse Company. They drive the axles through gearing which reduces the axle speed to one-fifth that of the motor spindle. One charge of the battery is sufficient for a run of 44 miles. The tractive force is found to be 17·6 lbs. per ton at starting, and 8·8 lbs. per ton when running on the level at a speed of 11 miles per hour.

NICKEL steel is likely to be largely used in automotor construction, and it is useful to note that the resistance of nickel steel to the attack of water increases with the nickel contents. The least expanding alloys, containing about 36 per cent. of nickel, are sufficiently unassailable, and can be exposed for months to air saturated with moisture without being tainted by rust. With a view of testing the expansion of nickel steel, experiments have been carried out by allowing measuring rods to remain in warm water for some hours, according to the *Iron and Coal Trades Review*. They were not wiped off when taken out, but were exposed for a longer period to hot steam; but the lines traced on the polished surfaces were not altered. The rough surfaces, when exposed to steam, were covered after several days with a continuous, but little adhesive, coat of rust.

A COSTLY experiment in æronautic automobilism with an alleged steerable balloon has recently been carried out in the presence of a large number of officers near Berlin, but proved a complete failure. Both the car and the balloon were entirely of aluminium, and were driven by a benzine motor. They were made in the barracks of the Balloon Detachment in order to keep the matter secret. The balloon rose to a height of about 1,000 feet, and then turned round, but, failing to make any way against the wind, was driven back. It disappeared behind a cloud, and was not seen again till it was found in a field. The car was bent up under the weight of the balloon, and both were badly damaged. The experiments are said to have cost about three million marks, exclusive of the cost of the balloon, which came to grief, and which took four years to construct.

MR. C. D. PHILLIPS has lately astonished the good people of Newport (Mon.) by appearing before them on a motor-cycle, says a local scribe. The motor is started by pedalling the machine forwards, and after about two turns of the pedals it begins to propel the tricycle, leaving the rider nothing to do but to steer. It will mount a gradient of 1 in 10, notwithstanding its weight—150 lbs. Machines of this kind cannot possibly be constructed lighter, as a certain weight is required to reduce the vibration which any vehicle driven by a motor is subject to. The oil reservoir will hold a sufficient quantity to last 50 to 60 miles, whilst the accumulation will even hold out three times as far. In the run from London to Brighton, 12 months ago, the new Beeston was the only British-made motor which reached its destination. The speed may be varied, and in going up-hill the pedals may be worked to assist the motor. The price—70 guineas—does not seem exorbitant when a thoroughly good tricycle will run a purchaser to £30 or £35.

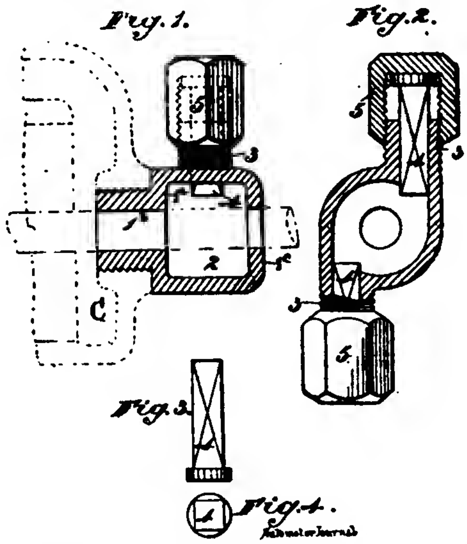
The Post Office and Automobolism.—The announcement that we make elsewhere to the effect that a contract has been entered into between the Postmaster-General and Messrs. Julius Harvey and Co., whereby the latter engages to carry the Redhill mails for a period, is extremely satisfactory, as it shows that the officials are quite alive to the advantages of automobilism for parcels and mail purposes. Messrs. Julius Harvey propose to use a steam van, and we are bound to say that we think their choice a good one. We understand that the negotiations between the parties have been proceeding for some time, and great credit is due to Messrs. Julius Harvey for the tact and pertinacity they have displayed in meeting the departmental objections, and also to the Post Office officials for their commendable departure from official tradition in thus taking up automobilism at such an early stage. If, as we make no doubt, the present experiment succeeds, we shall soon see the present mail coaches superseded by automotor mail vans—a consummation devoutly to be wished.

A NEW STUFFING BOX.

MESSRS. THORNYCROFT have recently patented a novel form of stuffing box, and one which offers considerable advantages for automotor vehicles. The idea is distinctly novel, and we should say eminently practicable. As will be seen on referring to the accompanying drawings, the ordinary gland or stuffing box is dispensed with, but into the hollow chamber in which the shaft works is placed a suitable packing material, preferably white metal shavings or Delaunay Belleville shot packing.

As will be evident from the construction of the stuffing box, the packing material may be pressed more or less tightly according to the extent to which by the screwing up of the cap-nuts the blocks are forced into the interior of the box.

Referring to the drawings, Figs. 1 and 2 show vertical sections, at right angles to each other, of a stuffing box. In this example the following parts are integral, that is to say, the lateral wall, 1, the inner end, 1ᵃ, an external screw-threaded neck, 1ᵇ, adapted to be screwed into the end, C, of cylinder, the outer end, 1ᶜ (which corresponds to the cover in an ordinary stuffing box), and the necks, 3; 2 is the chamber or space to contain packing material.



The inner end and neck, 1ᵃ, 1ᵇ, and the cover part, 1ᶜ, of the wall of the box are bored to fit the rod to be packed. The necks, 3, are externally screw-threaded, and have their axes tangential to the peripbery of the rod; 4, 4, are blocks (one of which is shown separately in Figs. 3 and 4) that fit into the tangential necks, 3, and project into the stuffing box, or in other words into the chamber which contains the packing that surrounds the rod or part packed; 5, 5, are cap-nuts that hold the blocks, 4, in place, and by means of which they can be forced to a greater or less extent into the stuffing box, so as to press the packing therein against the rod.

The packing Messrs. Thornycroft prefer to employ is that known as Wheeler's Fibrous Metallic Packing. This packing contains white metal shavings and fine graphite. The graphite tends to prevent the white metal shavings flowing into a solid mass that would be difficult to remove from the stuffing box.

The Prince of Wales and Automobilism.—After languishing in the cold shade of neglect by the aristocracy the motor-cab has at length emerged into the comfortable warmth of Royal approbation. His Royal Highness the Prince of Wales has done the industry a good turn in his own good-natured way, *i.e.*, by quietly and unostentatiously making a journey in a motor-cab. When proceeding from Marlborough House to the railway station for Sandringham the other day the Prince took one of the ordinary electric cabs plying for hire in the street, and travelled in it with his Equerry by his side. His Royal Highness appeared to enjoy the experience, and I shall not be surprised to hear, says a well-informed correspondent, that the motor-cab has been placed in the list side by side with the hansom cab as his favourite vehicle.

CONTINENTAL NOTES.

The Automobile Club of Paris has 1,150 members.

M. Serpollet has patented a new form of oil-burner, somewhat on the Bunsen principle.

MM. Panhard and Levassor are constructing a 20 H.P. Petrol motor-van for the next Concours des Poids Lourds.

In spite of all protestations and complaints the French Ministry has definitely decided to enforce the tax on motor-vehicles.

M. Fulcrand, an abbot, of Marseilles, is having a steam automotor built; it will have a compound engine and a Longuemann boiler.

We regret to learn the death of M. Roger, a well-known constructor of automotors and inventor of the oil-motor which bears his name. He was only 47 years old.

During his recent stay in Paris Sir David Salomons presented a beautiful snuff-box to M. le Comte de Zuylen. On the lid is a picture representing an electric cab.

Petroleum merchants are having a good time in France, thanks to the spread of automobilism. One merchant has spent no less than 600,000 francs with one house alone.

The Paris Municipal Council has fixed the following prices for electricity:—For lighting, 10 to 12 cents. per hecto-watt hour. For automobilism (we presume charging batteries is meant) the price is 4 cents.

Messrs. De Dion and Bouton, with the view of increasing the popularity of their petroleum motor tricycles, are organising for next year a series of road races for these machines, in connection with which prizes will be put up for competition.

The German Post Office authorities have decided to employ automotor-vehicles. They have ordered two types, one a light vehicle for the collection and delivery of letters, and the other a heavy description for parcels, &c. Both will be four-wheeled vehicles and will have Daimler motors.

M. Mors has brought out a new kind of variable speed gear. We have not yet seen a speed gear which can by any logical process be called "variable." If M. Mors has really made a variable gear he need work no more. We expect, however, that it is a change speed gear that is meant.

It is stated by the *Traccion Ferroviaria* that at the Krupp Works, Esson, locomotive axles are now made of steel alloyed with 15 per cent. of nickel, which gives a resistance of 99 kilos. per square millimetre, or 50 tons per square inch, while with the addition of a little chrome, the steel acquires the almost incredible resistance of 180 kilos. per square millimetre, or 114 tons per square inch.

The following is the new tariff of the Automobile Club:—Breakfast, including wine, 3 francs 50 cents.; dinner, including wine, 4 francs; but on Wednesdays the dinner, including wine, is 5 francs. The charges are moderate enough, and we hope that British Automobile Clubs will charge equally moderate prices.

The official report of the Les Poids Lourds will be sent to all the principal State officers in France, as well as to all officials who are in any connected with transport. In this way much provincial ignorance which mayors, policemen, and other governors of the earth exhibit, not only in France but also in England, will be dispelled. We would suggest that the Home Secretary should procure a number of copies, and present one to every magistrate, J.P., and head constable. It would be a liberal education to them.

The cyclist may not be altogether blest in this country, says the *Daily News*, but it would seem, from remarks made by the lively *Revue Mensuelle* of the Touring Club de France, that he is far better off than his brother across the Channel. The *Revue* says:—"The Paris coachmen in the first fortnight of October killed 18 persons and wounded 112. Not a voice was raised in protest. C'est la Liberté! The cyclists, five times more numerous, caused during the same period five or six accidents. The entire Press rose as one man, while the magistrates emphatically declared that the streets are for the carriages and foot passengers, and for them only; and they proclaimed woe to the cyclists! C'est l'Egalité!"

In the forthcoming motor-car race from Paris to Amsterdam, the following gentlemen have been appointed a commission:—MM. Berlier, Herard, Varennes, Recope, Baron de Zuylen, Comte de Dion, MM. Henri Menier, Andre Lehideux-Vernimen, Ballif, Rives, Comte de Chasseloup-Laubat, MM. Archdeacon, Barbet, Clement, Collin, Pierre Giffard, Jeantaud, L. Lemoine, de Lucensky, Gaston Menier, Paul Meyan, Panchard, Perignon, Peugeot, Pierron, Pozzy, Ravenez, Sir David Salomons, MM. Serpollet, Gastine, Michelin, Echwege, Baron Rognat, and M. Prevost; and in the Marseilles-Nice race to be held in March, 1898, Sir David Salomons, Bart., has been placed on the Committee to represent Great Britain.

According to a table prepared and forwarded to his Government by the United States Consul at Zurich, there are the following lengths of tram line operated by electricity in the various countries of the world:—

	Kilometres.		Kilometres.
Germany	713	Russia	16·5
France	311	Servia	10
Great Britain	142	Sweden and Norway	8
Italy	128	Bosnia	6
Switzerland	88	Roumania	3·5
Spain	53	Portugal	3·5
Belgium	39		

In France the automotor-vehicle is used to convey the sportsmen and sportswomen to and from the scene of operations. In England the idea of riding to a "meet" in a motor-vehicle would be received with absolute horror as being contrary to all rules and precedents made and established and sanctioned by the custom of ages. Many a country squire regards a motor-vehicle as an outrage; but as for using it for hunting! why such an innovation is calculated to shake the foundations of society. However, in France its use for this purpose is extending, and we are told that the fashion has been set by the Duchess d'Uzès, who is an ardent automobilist and sportswoman. Her Grace drives to the hunt or shoot in a Delahaye. Another leader of French society, M. Përier, pursues the chase on a De Dion tricycle.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents:—*

London: POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale: BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.

Birmingham: J. MCCANN, 37, Union Street.

Manchester: JOHN HEYWOOD, Deansgate.

Newcastle-on-Tyne: C. C. ROSS, 35, Side.

Paris: HOMÈRE MOREAU, 97, Rue Nollet.

Victoria (Australia): PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

DECEMBER 15TH, 1897.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

[*For full programme and proceedings of the Self-Propelled Traffic Association, see p.* 105.]

1898.

Jan.	Exhibition of Locomotion and Engineering, Rifle Barracks, Belle Vue, Bradford.
Jan. 11 ..	Liverpool Cycle and Motor-Car Exhibition, Liverpool.
Jan. 20–29 ..	Midland Cycle and Motor-Car Exhibition, Bingley Hall, Birmingham.
Feb. 3–12 ..	Sheffield Cycle, Motor-Car, and Accessories Exhibition, Drill Hall, Sheffield.
Feb. 14 ..	Yorkshire College Engineering Society—"The Steam Turbine Engine and its Applications," by John D. Bailie (C. A. Parsons and Co., Newcastle).
March 6 and 7	Marseilles and Nice Race (organised by *La France Automobile*).
May 2, 9, 16, 23	Society of Arts Cantor Lectures—"Electric Traction," by Prof. Carus Wilson.
May 24 ..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
June	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
July 5.. ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

A. SERENA.—What you ask for would entail an enormous amount of labour to send you personally. You will find the whole of the particulars you ask for in our 1898 "Automotor Pocket Book of Automotive Formulæ," which will be published about the last week in December.

YORKSHIRE MOTOR-CAR CO.—We have sent your communication on to Messrs. Halstead and Horsburgh.

T. J. MERCER (Sligo).—(A) The JOURNAL shall be sent you as instructed. (B) The address of the manufacturers of the Scotte Motors is Société des Chaudières et Voitures à Vapeur Systême Scotte, 56, Rue de Provence, Paris.

WOODHOUSE (Derby).—The books shall be sent you immediately upon publication. Messrs. Halstead and Horsburgh's address is Whitefield, near Manchester.

RICHARDSON (Leeds).—(A) We should say distinctly not. (B) Before doing anything write Messrs. Julius Harvey and Co., Consulting Engineers, at 11, Queen Victoria Street, London, E.C. They have the matter in hand.

AUTOMOBILISM IN LIVERPOOL.

IN Liverpool the question of automobilism has been taken up with commendable zeal and enterprise—not, we think, from any academic or philanthropic desire to cheapen the cost of transit of the poor man's coals, or his beer, or anything else which is his, but in a practical spirit of enlightened selfishness, which, after all, is perhaps the best way of regarding any question of public convenience. Liverpool and Birkenhead are the natural basins into which flow the vast streams of manufactured products from, to pursue the analogy, the commercial watershed of West Yorkshire and East Lancashire. Into Birkenhead and Liverpool comes also the bulk of the North American produce; and, although produce grown thousands of miles away is brought into Liverpool at what are ridiculously low charges for freight, and finished goods are carried from Liverpool to the ends of the earth at equally ridiculously low charges, complaints are, and have been for years, rife of the heavy costs that the manufacturers in Yorkshire or East Lancashire or their consignees abroad have to incur before the raw produce can reach the one or the finished product be used by the other. If the freight charges on, say, a parcel of cotton-spinning machinery made in Manchester and intended for erection in Japan, or the same charges on a Colorado ox for its transport to Birkenhead and its delivery as dead meat to Manchester, be examined, it will be seen that the heaviest item is railway carriage. In South Lancashire perhaps more than in any other part of the kingdom, the railway interest is all powerful—it has practically a monopoly. Attempts have been made from time to time to introduce competing means of transit, and the Manchester Ship Canal was built partly with this object. Owing to causes which need not here be discussed the Canal has failed utterly in this respect, and at present it is to all intents and purposes a more or less useful adjunct to the L. and N. W. R. Just as on the physics of metals there is an "elastic limit" or point beyond which stress is accompanied by deformation or strain, so in individuals there is a human elastic limit of endurance. Railway, telegraph companies, and other large trading corporations are well aware of this, what we may term law of public stress and strain. To give an example:—The Standard Oil Trust and their agents, the Anglo-American, the houses of Nobel and Rothschild between them fix the price of petroleum. They don't compete because they pursue a policy of enlightened selfishness. Between them they may advance the price of oil by a few cents, or they may lower it by the same amount. The difference may mean thousands or millions of profit, which comes out of the consumer's pocket, and he does not mind a bit. There is, however, a price beyond which he won't go, and the companies dare not attempt to reach this limiting figure, or they would arouse the apathetic selfishness of the public. Really the remedy for dear oil or heavy railway charges lies very largely in the hands of those who pay. Few of us can afford the luxury of an oil well in the back-yard, and still fewer of us own ships or railway shares; but in Liverpool as in Manchester, or indeed in any large city, the formation of automobile carrying companies, requiring but little capital to run them, might well be attempted. As will be seen from the excellent paper read at Liverpool before the Self-Propelled Traffic Association by Mr. Worby Beaumont, an excerpt of which is published in our present issue, that gentleman does not think heavy automotor vehicles, weighing, when loaded, some 14 tons, admissible, chiefly because of the heavy wear on the roads and the steepness of the gradients in and around Liverpool. He is inclined to favour automotor vehicles carrying from five to six tons. We quite agree with Mr. Worby Beaumont that by the adoption of a plate railway, such as suggested by Mr. A. Holt, these objections would vanish or be materially lessened. On the other hand, plate railways would hardly be admissible on the steep gradients that are found leading from the docks to the open country. Indeed, no more difficult site for the development of heavy automotor traffic could be well imagined than Liverpool. The railway companies have had to cut and tunnel extensively, and this opens up the question whether, after all, a light railway would not meet the case. Inasmuch as it would involve tunnelling, we think that if it is decided to have a light railway it would be as well to have an ordinary heavy railway, which, it is safe to say, would be in the Receiver's hands inside of twelve months. A railway of any sort in this district has, as is well known, the option of working with existing companies or winding itself up. Again, take this more practical instance. One steamer discharges in the Alexandra Docks, another in the Toxteth Dock, some six miles apart. What the merchants and shipowners, so ably represented by Messrs. A. Holt and A. Jones, want is the power to send an automotor vehicle to one or the other, and take, say, Smith's consignment of 25 or 50 bales of cotton direct ex wharf to the factory at Warrington, Salford, Manchester, or Oldham. Can it be done? It can, providing that local authorities and those owning these automotor vehicles will arrive at some equable arrangement as to maintenance of roads and bridges. After having witnessed, as we did, the exceedingly onerous French trials at Versailles, we are more than ever convinced that heavy automotor traffic can be advantageously undertaken even in Liverpool; and we speak with some small local knowledge. A heavy railway is out of the question. A light railway would be objected to by the Corporation, as interfering with their tram schemes; moderate automotor vehicles, such as Mr. Worby Beaumont suggests, should be tried first, and their economical limits determined; heavier ones might then be built. Unfortunately there was no discussion on Mr. Beaumont's paper, and the rather pessimistic impression that prevailed to the effect that heavy automotor vehicles are not possible could not be corrected. Seeing how deeply interested Liverpool is in this question, and how, with a capital of less than £10,000 the whole thing could be exhaustively threshed out, it is to be hoped that steps will be taken by those most concerned to test the various views put forth. It is useless, it is stupid, to say, as do the London bus and tram directors, "We are waiting for the 'really satisfactory' motor," because the perfect motor vehicle does not exist, any more than the perfect steamship or the perfect mangle, and probably never will in our time. G. H. L.

THE RISKS OF HORSE DRIVING AND RIDING.

When the poet of old wished to show up the general folly and stupidity of mankind he said: "Some put their trust in chariots and some in horses," thereby implying that in so doing they were relying upon something unstable, uncertain, and unsafe. In those days, when chariots were the only vehicles known and horses or other animals the only sources of tractive power, the user had no choice. He either had *de facto* to put his trust in them or leave them alone. Nowadays there is really little or no excuse for putting any trust in horse-drawn vehicles. Yet such is either the influence of the barbaric instinct or the force of habit that many people prefer to ride or drive horses who might with advantage to themselves and their families prefer the unquestionably safer automotor vehicle. We ourselves, in common with other humble members of the community, are too often forced by circumstances to entrust our lives to the London jehu who drives a bus or cab; we, however, never do so willingly, and could we afford it nothing would ever tempt us to risk an otherwise useful and blameless existence by entrusting it to chariots and horses.

It may certainly be advanced that little risk is entailed when dealing with the poor, overworked, underfed, broken-spirited animals that one is accustomed to see in London and Paris cabs and omnibuses; but one never knows, even these creatures are at times afflicted with a kind of equine hysteria, and under the impulse of a glorious discontent with their unhappy lot they make one last mad rush for freedom and are usually only stopped when they have succeeded in knocking down a lamp post or two or smashing the plate glass of a shop. Far more dangerous is it in the country, where horses are usually better treated, especially when, as is often the case, they are not too much worked and are only too glad to bolt at top speed on the slightest provocation. How many valuable lives have been lost through this cause it would be difficult to say, but every now and again we read of sad and deplorable accidents occurring—all the more sad and deplorable because the risk is so utterly unnecessary. It is not too much to say that were hunting and driving pastimes indulged in by the working classes we should be assured "that legislation was imperatively called for to prevent the loss of life of British working men and women." As it is, these pastimes are indulged in only by the "classes," and so nobody—at least no "popular representative"—cares whether the annual loss of life occasioned by riding or driving high spirited horses is much or little. Leaving this aspect of the question, it is undoubtedly the fact that riding or driving horses is attended with a much greater risk than any other form of locomotion, and it is no doubt the element of danger involved that makes these pastimes such a favourite "sport," and this is enhanced by the absolute uncertainty of what the horse is going to do. Indeed unreliability is, perhaps, more than any other the distinguishing characteristic of the animal. We are led to make these remarks in consequence of the sad and deplorable death of a very distinguished lady—a personal friend of Her Majesty, and one, moreover, greatly esteemed by all classes—we refer to the late Countess of Lathom. It seems that, according to the report published in the daily papers, the Earl and Countess of Lathom had invited a large number of guests for the opening of the shooting season on their Lancashire estates at Ormskirk, and on the morning of the 23rd ult. his lordship and his guests shot over the covers. Several ladies were present in carriages. After luncheon the Countess of Lathom left the party in a phaeton, drawn by two ponies, which she herself drove, her companions in the vehicle being two other ladies. A coachman was in attendance. Not far from the entrance to Lathom Park one of the ponies became restive, and made a sudden plunge, which caused the carriage to swerve to one side of the road, where there runs a somewhat deep brook. The wheels slipped over the bank, and the vehicle toppled into the stream. The Countess of Lathom fell into the water, and the carriage rolled upon her. The other ladies, as well as the coachman, were also thrown out, but escaped the falling vehicle, and suffered little injury save a few bruises and the shock inevitable in such an occurrence. The coachman at once procured assistance in the neighbourhood, and the carriage was lifted out of the brook. Her ladyship was found under it in the water, and it appears that in the fall she must have been kicked by one of the struggling ponies. The body was at once removed to Lathom House, and Dr. Pendlebury, of Ormskirk, was summoned. He expressed the opinion that death was due to concussion of the brain.

That such an accident should occur is always probable. It only requires the slightest cause to make a horse restive, and he then becomes a maddened and unmanageable brute. We can only express the hope that these accidents will become rarer in future. There is no reason whatever why precious lives should be thus risked. The ordinary bicycle is infinitely safer, more reliable, and cheaper in every way than the best horse; while a well-designed automotor vehicle is beyond question the only conveyance suitable for ladies.

*** The General Post Office authorities have within the last two or three days arranged a contract with Messrs. Julius Harvey and Co., of 11, Queen Victoria Street, for the regular conveyance of parcel mails between London and Redhill, to commence on Thursday night, the 16th instant. The van to be employed will be on the "Lifu" steam principle, and will have to carry all the heavy Christmas mails as a start. This contract has been entered into after thorough inspection, &c., by the Secretary and the chief officials of the Post Office.

AUTOMOBILISM AND THE LONDON COUNTY COUNCIL FIRE BRIGADE.

We do not profess to be prophets, but we claim to know something—not much, perhaps—of the subjects upon which we write. In last month's AUTOMOTOR, writing on the Fire Brigade, we said:—

"Speaking generally, it must be said that most of this enormous plant is antiquated and obsolete in design, and generally inefficient: there is not a single steam motor which works at anything more than 150 lbs.—a comparatively low pressure. There is not a single electric pump. Flexible metal section hoses are things utterly unknown to the Fire Brigade, as are water towers and other improved means for dealing with fires. Lastly, *there is not a single automotor fire engine in the first city of the world.* Can it be wondered at that London fires are so frightfully destructive and so costly? Little or no improvement has been made in the plant of the Fire Brigade since the days of the old Metropolitan Board of Works."

We—not being prophets—did not anticipate that such an absolute and positive proof of our contention would be afforded within such a short time, yet, as all the world now knows, London has narrowly escaped destruction by fire simply because we have no means of dealing with large conflagrations. When flame is applied to a combustible in presence of free oxygen total combustion ensues with greater or less rapidity. By various means the combustion may be checked or stopped altogether. If the combustible is of value the scientific method of treatment would be to stop the combustion with as little damage to the unconsumed portion as possible. Now fires in cities have from time immemorial been frequent, costly, and destructive, and it would be a reasonable assumption that at the end of the nineteenth century fire extinction and prevention was a fine art. Yet what are the facts? All the more serious fires which have occurred in London during the last 20 years, including the enormous one on the 19th ult., have been distinguished by the same characteristics; these are:—

(*a*) A small fire has become a large one because there is no such thing in London as scientific fire prevention.
(*b*) The fire has always involved the total destruction of the premises upon which it has occurred.
(*c*) The fire has always extended to adjoining premises.
(*d*) The damage done by the Fire Brigade is a large proportion of the total loss.
(*e*) The operations of the Brigade are mainly confined to preventing the extension of a fire *after* the latter has become, in vulgar parlance, "well alight."

It must, of course, be understood that we make no reflection upon the *personnel* of the Brigade. We quite admit that all firemen are "gallant." We suffer from no lack of brave and gallant men and women in all walks of life. But bravery and gallantry, as all history shows, are of little avail without good organisation and appliances, and it is just these two matters which, in the case of the London Fire Brigade, are so susceptible of improvement. The Fire Brigade has been a kind of spoilt child with the public, and, like all spoilt children, it is impatient of criticism and control, but greedy of applause. If one observes the proceedings at a fire, it must be conceded that, as a rule, the men are fairly well handled; but there is too much theatricality, too much of the polished brass and tinkling cymbal for efficiency. A steam fire-engine drawn by horses dashing up to a fire no doubt tickles the eyes and ears of the groundlings, but it makes the judicious grieve to reflect that this costly and inefficient method of propulsion is yet with us in the land, and that this wretched two-horse show should be trotted out as an up-to-date fire appliance of the first city of the world.

In order to give an idea of the obsolete character of the so-called fire engines used by the London County Council we give the following particulars:—The boilers are of iron of a design that is nearly 50 years old; they carry steam at the comparatively low pressure of 100–120 lbs., and can only by dint of hard firing and careful nursing and stoking maintain it at that. The pumps are of the obsolete single cylinder bucket and plunger type; their maximum-rated (*sic*) capacity is 350 gallons per minute, usually they are doing well if they deliver 200 gallons per minute. This water is discharged through a 1¼-inch nozzle, and is supposed to reach to a height of 160 feet—as a fact 80 feet is nearer the mark. To work this amplified garden squirt no less than 30 I.H.P. and six men are required. These pumps have a *modulus* of about ·30 only; in other words, they are very inefficient. Consequently, in order to throw any stated quantity of water on the scene of a conflagration three times the number of pumps, and therefore three times the plant and appliances, is required than should be necessary. We understand that there is only one fire engine in the London Fire Brigade that can deliver 500 gallons per minute, whereas in many provincial and Continental cities the engines can throw from 1,500 to 1,800 gallons per minute, the average capacity of the London squirts being about 200 gallons per minute. One of the disadvantages attending the use of such small capacity engines is the small size of the projected stream of water and the low pressure. The consequence is that when these garden-squirt streams are projected into a fierce fire the water is flashed into steam, and much of the latter becomes dissociated and actually feeds the flames; in short, in not a few cases the Fire Brigade's efforts increase the conflagration. So long as pure water is used it must be delivered in large volumes at high pressure. This means large, powerful, automobile engines, of not less than 50 E.H.P. It also means the use of water towers—things utterly unknown in London. Naturally enough the glaring inefficiency of the Fire Brigade and the danger of repeating the great fire of 1666, which was not at all improbable, aroused much feeling in the Press. We need not notice the comments made in the lay journals, but the phenomenal ignorance displayed by the *Daily Telegraph* deserves a word. In a leading article on the Fire Brigade it says:—"Motor fire-engines have been suggested after the American model, but these would be almost as much embarrassed by narrow winding lanes as horses." We need hardly say it is just this very property of being able to penetrate where horse-drawn could not that is one of the many advantages of automotor vehicles. This is the unanimous verdict of all competent persons who have ridden in them. Turning to the professional journals we find the Fire Brigade regarded much from our point of view; thus in a recent issue *Engineering* says:—

"But what are the lessons of this enormous conflagration? Those who attended the fire, and have afterwards examined the ruins, can only tell the same tale. The lesson is, that we seem to know but very little about fire protection in London, and that the sooner we take up the matter, the better for all concerned, more particularly if we remember the rate at which the metropolis is growing in extent, the greater costliness of our structures, and their contents. We are not only much too far behind other countries in taking preventative measures, but we are certainly also not ahead of other modernly-equipped cities as regards fire-extinguishing, excepting, perhaps, in the physique and activity of our firemen, our horseflesh and driving, our new fire-stations, some of our engines, the cleanliness and brightness of our brasswork and red paint. Our Fire Brigade can also boast of being able to play to the gallery better than many of their colleagues elsewhere. As regards organisation, general management, and appliances, tactics, and, what is perhaps most serious, the principles on which our fire service is based, we are not only worse than many other cities, but actually the laughing-stock of the foreigner, who we are so apt to despise. There is not the least doubt that

. . . . what was the model brigade of the world in the seventies certainly no longer holds that position. Other nations learnt from us at that time and adopted our methods, improved and developed them, whilst we have practically stood still in everything, excepting numerical strength."

In order to improve the present inefficient, costly, and theatrical service we make a few suggestions:—Amendment of the Metropolitan Building Act; compulsory installation of hydrants; drawing water from the mains and of cisterns containing chemical fluid* on the roofs of warehouses and buildings containing easily inflammable goods; the erection at salient points of electric fire-pumps, these should be either fixed or automobile, in the latter case reels of armoured cable would be required; the replacement of the present fire-engines by automobile engines, and the use of water-towers; and lastly, the reorganisation of the brigade.

REVIEWS OF BOOKS.

"Motor-Cars and the Motor-Car Act, 1896." By WALTER SMYTH. 2nd edition. (Dublin: Hodges, Figgis, and Co) Price 6*d*.

THIS is a little brochure which in four chapters contains all the information that the layman need know of the law of motor-cars. The author is evidently an enthusiast, but is not an engineer, or he would not say that steam has been superseded by its two rivals (why rivals?) electricity and petroleum. He continues: "There is no doubt that in regard to economy petroleum is undoubtedly (*sic*) the cheapest, but there are other desirable qualities to be looked at, such as bulk and safety, and of these electricity has the *advantage*." Whether it be an advantage to have the bulk necessitated by the use of accumulator cells may be questioned. Again, the piston of the Daimler motor is *not* "driven *up* and down" the cylinder by small explosions, &c. In his legal knowledge the author is much better posted, but as there are at least two or three standard works on the subject, it is easy to ascertain what the law is. Chapter IV relates to the law for Ireland, which does not differ substantially, if at all, from that of the United Kingdom. The work is certainly worth its price, and as it can be easily carried in the pocket *its* small bulk is an advantage.

The Engineering Magazine.—The November number of this is to hand, and as usual contains plenty of matter interesting alike to the engineer and business man, especially if the latter is engaged in transportation work. The first article by Mr. H. S. Maxim will be read with more than ordinary interest at the present juncture, it is entitled "The Effects of Trade Unionism upon Skilled Mechanics." Mr. Maxim, as a strong individualist, has little or no sympathy with trades unions. We have always regarded such bodies as useful, but imperfect and crude, and as education advances their power will in the nature of things decrease, simply because no half-dozen educated men could, if they were made of common or garden clay, consent to have their individuality sunk in a dead level of mediocrity—we are too selfish. Mr. Maxim gives many examples of the methods of trades unionism as applied to the lessening of production and the peculiar views entertained by members of unions. One instance is the following. He says:—"I remember that on one occasion several delegates were sent to us by the Amalgamated Society of Engineers with a complaint that we were allowing an unskilled man to work a Brown and Sharpe milling machine. The chief spokesman was a very young man. He said that this machine was of a very high order, and ought by rights to be worked by a man skilled in the art, and not by a mere labourer. We informed him that the man who was operating the machine was indeed a skilled man, that he was able to do the best work done in the place, and that he had worked a milling machine for 30 years, beginning several years before the spokesman himself was born. We asked him if he could do better or quicker work than the man complained of. He said that he did not think he could do it as well. He admitted that the man was able to do the work, but said that technically he was not a skilled mechanic, because he had not served as an apprentice before he was of a certain age. Consequently, no matter what he might do afterwards, or how skilful he might really make himself, he must remain for ever, technically, an unskilled workman, work for lower pay, and be debarred from doing the fine work that he was so well qualified to do. I found that this same feeling existed all over England." Mr. Maxim concludes:—"It appears to me that trade unions oppose, and always have opposed, the use of machinery which enables work to be turned out quickly and cheaply, and I believe there has never been a machine, apparatus, or system introduced into England which has helped to give her the position which she now occupies as a great manufacturing nation, which has not been opposed tooth and nail by the ignorant and unthinking who make up the rank and file of the English trade unions." We would correct Mr. Maxim on one point—he must except the cotton operatives from the last charge.

"Future Supremacy in the Iron Markets of the World," by Mr. J. Stephen Jeans, is, as might be expected from such an authority, a useful contribution. He shows what a leading part the United States are playing in the production of iron. We ourselves remember carrying "pig" to the States; now it is imported. Mr. Jeans shows also that much of the credit for the present position of the United States is due to the American working-man, who is more highly paid, works longer than our own, and who, by his superior intelligence, welcomes every possible improvement in machinery, because it enables him to do more work, and therefore earn more money in a given time. "Modern Wharf Improvements and Harbour (we beg pardon, we should write Harbor) Facilities," is the second of a series of articles which was commenced in the last issue. We commend them to our friends the S.P.T.A. of Liverpool. "Cost-Keeping Methods in Machine Shops" appeals more directly to managers, and is of little general interest. "American Tall Buildings" is a smart criticism of the architectural methods pursued in the States. The author, Mr. S. Capper, is quite content to let our American friends rejoice in their tall buildings. He, as we do, prefers more humble dwellings. "The Enormous Possibilities of Rapid Electric Travel" is also a continuation of a series of articles on this subject. The authors simply revel in estimates and statistics, and we have no doubt but that this contention will be keenly criticised on this side.

"The Economical Governing of Steam-Engines" is a contribution to this important subject by one of our greatest living authorities. Mr. John S. Raworth is, we need hardly say, the recognised successor of Willans, and the present paper is largely an exposition of the now well-known "Willans' Law." We cannot do justice to this article here, and beyond recommending it strongly to engineers we leave it. A paper on "Cement in Construction Work" and one on "Ore-Loading on the Great Lakes" are useful but not particularly informing. "English Railway Stations," by Mr. Whitehead, is an interesting account of the handling of goods in large depôts. It is well to know that the companies kindly store produce in their warehouses rent free for a month. "Civil Engineering" is dealt with by Mr. Graham Harris, C.E., who in a strictly professional manner tells us that in Greater London, with its population of some five and three-quarters or six millions, there has to be disposed of every week a weight of dead humanity equal, roughly speaking, to some 100 tons, or something like 15 tons per day for every day of the week, and "this although Greater London is probably the healthiest city in the world, the average death rate being as low as 19 per 1,000 inhabitants per annum. It is a gruesome thought," continues Mr. Harris, "and a gruesome calculation, but the fact has to be recognised that, to put it in another way, a heap or pile of dead humanity some 3 feet high, 6 feet wide, and more than 250 yards (750 feet) long has to be disposed of in Greater London every seven days." Mr. Jas. Swinburne discourses pleasantly on the electrical engineer, and he tells us—and we quite agree—that it is better to sell paint and varnish than to know much mathematics. Mr. Worby Beaumont deals with "Mechanical Engineering," and we give an excerpt from his paper in another place. Altogether a readable magazine.

* The following fire-extinguishing composition is cheap and effective. Six solutions should be prepared as follows:—

1.	Ammonium chloride	0·44 lb.
	Water	4·4 galls.
2.	Calcined alum	0·77 lb.
	Water	2·2 galls.
3.	Powdered ammonium sulphate	6·6 lbs.
	Water	1·1 galls.
4.	Common salt	4·4 lbs.
	Water	8·8 galls.
5.	Sodium carbonate	0·77 lb.
	Water	1·1 galls.
6.	Soluble glass	9·9 lbs.

The whole of these should be mixed together in the order indicated, and 4·4 galls. of water are then added to the result. This solution is very useful for small fire-extinguishers. By taking 100 or 1,000 or 10,000 times the quantity a larger fire could be dealt with.

The Electrical Review has enjoyed 25 years of existence, and has fittingly celebrated the event by the issue of a double number, in which the progress of electricity is reviewed during that period. In these days of fierce competition between newspapers—competition which in too many instances produces a moral depreciation on the part of proprietors and editors—it is pleasant to know that there are some journals which have always maintained a high journalistic and scientific standard. Such a journal is *The Electrical Review*, and the present high position of the paper in the scientific and technical world is due to two things—ability and probity. *The Electrical Review* has indeed been a kind of literary crucible into which have been put many kinds of frauds and impositions, from primary batteries to medical belts, and refractory indeed has been the matter that could withstand the heat of the editorial fire. In this way it has rendered a great public service. The present number is a most instructive one; it contains articles from the pens of the principal electrical engineers, and the reader is enabled to survey the whole field of electrical science and industry.

The Carriage Monthly Daily is the somewhat confusing title of a very live Transatlantic journal devoted to the carriage industry. It is celebrating its silver anniversary, having been founded in 1872. In consequence of having reached this term of middle life, and having had, as its advertising pages bear copious witness, a prosperous career, it has come out on this special occasion as a thick volume, which is worth preserving for many reasons. In no country has the art of carriage building been so improved as in the United States. American makers taught us how to design structures possessing the maximum of strength and rigidity with the minimum of lightness and section. Wood-working machinery is a distinct American speciality, and it is really marvellous to see how light, and yet how strong, American carriages are. All these and kindred things it is the business of *The Carriage Monthly Daily* to record, and we congratulate our contemporary upon the prosperity it has achieved. The present volume is not only a review of the United States carriage industry, but, as the journal is published at Philadelphia, there is a long series of photographs of the more principal points of interest in that interesting city. The book is a very creditable trade production, and we congratulate Mr. Wade upon it.

CATALOGUES.

MESSRS. ELLIOTT BROS., the well-known manufacturers of mathematical and mechanical apparatus, have recently issued a new price list, which is very well illustrated and got up.

THE Humber Cycle Company send us a well illustrated catalogue of their specialities in cycles and their accessories. The "Humber" is too well known to need any description, but perhaps the best proof of the excellence of Humber cycles is to be found in the rather high prices that the Company is able to command.

WE have also received from the Humber Company their catalogue of automotor vehicles, or more properly automotor bicycles. These are made to be propelled either by light oil motors or by storage cells. For their tandem pacer they claim to have obtained a speed of 40 miles per hour. We rather prefer the look of their motor tricycle, which is driven by a 2¼ H.P. motor. We notice that the Humber Company make a compact, heavy, oil, two-cylinder motor, which seems well adapted for vehicle and launch propulsion.

FROM the Reliance Lubricating Oil Company, of Water Lane, Tower Street, London, E.C., we have received a price list of their various brands of lubricating oil, which, from the tests, &c., seem to us eminently well adapted for automotor purposes. These oils are non-corrosive and do not absorb oxygen, hence they do not "gum" or clog. We notice a well designed tank or drum made by this firm which is well suited for the storage of petrol and other light or heavy oil. We hope no user of petrol will ever store it in a cask. Mentioning casks reminds us that this firm are issuing to their friends and clients a china inkstand shaped like a petroleum barrel; this is mounted on a broad base and forms a useful office utensil.

CORRESPONDENCE.

*** *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

THE MONOPOLY OF AUTOMOTOR MANUFACTURE.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Several engineers like myself would like to manufacture motor-cars, but, at the same time, do not care to do so with the awful threats and claims made by the British Motor Syndicate as to their master patents. I should like to ask through you what their patents are:—

(1) Do they consider that the combination of a carriage and steering gear with springs and axles to be one of their master patents?
(2) Do they claim the use of all kinds of gear wheels?
(3) Do they claim sprockets and well-known methods of chain driving in combination with an oil motor?
(4) Do they claim combination of a cylinder, piston, crank-shaft, and fly-wheel?
(5) Do they claim the exclusive combination of an inlet valve and exhaust valve?
(6) Do they claim the exclusive right to use benzoline or heavier oils?
(7) Do their master patents cover all systems of carburetting?

If you could kindly enlighten me and several of your readers on these points you would greatly oblige a large body of engineers who would like to take up this new industry.—Yours truly, PETROL.

P.S.—I should also like to know what use Lanchester's Patent Gas-Engine Starter is for motor-cars fitted with oil motors, as I understand they claim a great future for this patent.

[We should advise our correspondent to read carefully Sir David Salomons's paper in which he deals with the question of the validity of patents (*see* AUTOMOTOR, May, 1897). Our own opinion is that probably not more than half a dozen of these so-called "master" patents are valid, and what are valid are of little use, and so far as our own knowledge and experience extend we should say that an intelligent designer could attain the same end by a modified design.—ED.]

ROLLER BEARINGS.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Can you tell me whether the advantages of these bearings are sufficient to justify their substitution for ball bearings on the wheels of my two cars of about 15 to 20 cwt. each.—Yours faithfully, A. C. CRAGG.

Llandudno, *November 25th*, 1897.

[Yes, decidedly so.—ED.]

A GOOD PERFORMANCE.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—A run of 450 odd miles in five working days, averaging 9½ hours per day, is not a bad performance for a motor-car, taking into consideration the state of the roads at this season, and that the car in question was not a light carriage but a small "lorry" or drag, carrying a load of nearly half a ton, besides the driver and passenger.

A Glasgow firm, having purchased the car in London, decided to have it sent home by road, and accordingly a start was made for Scotland on the morning of Friday, November 12th, and Grantham reached about 8 o'clock the same evening; the second day's run ended at York, and so far the weather, although cold, had been dry, but on Sunday a perfect downpour compelled the voyagers to seek shelter in Durham at an early hour in the afternoon. Monday morning gave promise of a fine day and a pleasant time, but the promise was not fulfilled, as at about 12 o'clock a blinding snowstorm was encountered, and the inevitable breakdown occurred. This, however, was not serious, merely the slipping off of a driving chain owing to the links having stretched, and half an hour being lost over this, and the country being a difficult one, it was decided to put up for the night at Berwick.

Edinburgh was reached on the following afternoon, and Glasgow at 8 o'clock the same evening, the entire time spent on the road being, as before stated, 47½ hours. The car was driven by Mr. W. M. Hodges, the Manager of the London Motor-Van and Wagon Company (Limited), the builders, the motor being of the well-known Daimler type.—Yours faithfully,

THE LONDON MOTOR-VAN AND WAGON CO. (Ld.),
per W. M. HODGES.

London, *November 22nd*, 1897.

[While congratulating our correspondents upon their performance, we must say that it is no better than what ought to be expected. Automotor vehicles of good design, such as are referred to, are quite out of the experimental stage, and are as reliable as railway locomotives.—ED.]

A VERY SATISFACTORY LETTER.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Perhaps a few notes from Yorkshire may interest you. First as to ourselves. Business keeps constantly improving. We have sold cars each of the last three weeks and the number of enquiries increases. We shall directly have four cars belonging to private gentlemen in Bradford, and one or two other orders promised for the spring.

The pessimism of the Press is giving way to a more reasonable attitude and we look for considerable progress next year. We have plenty of room and shall be pleased to provide free storage and use of tools, &c., to any persons visiting Bradford with autocars. We can allow supply of petrol and charge batteries.

Cars on hire are in great demand; one of ours is now running in Sheffield, taking season-ticket holders free to an exhibition that is open there, the car being hired for the purpose by the exhibition authorities. Our cars have been to Bristol, Brighton, Norwich, Hitchin, Doncaster, Goole, Henley, Sheffield, Derby, York, Leeds, Ingleborough, Wakefield, Chester, Brandon, &c., all lent on hire.

We are also making sales on the hire purchase plan. A stranger car was in Bradford last week, a Daimler, owned by Messrs. Crossfield and Company, the soap makers. Motor-cars and soap seem to go together; three large soap firms, at all events, use cars for advertising.

We are working on a steam wagon and hope to compete at Liverpool in May next. Our motor exhibition has had to be postponed till later in the spring or summer. We could not get the Drill Hall in January.

An Arnold sociable of ours was carrying voters at the Leeds Municipal Election from 9 a.m. to 8 p.m. with only one hour's interval, and, although only built for two persons, was often carrying three and four people, and not one hitch all day with a 10 miles run from and to Bradford before and after the polling time.—Yours truly,

JAS. ED. TUKE.

Yorkshire Motor-Car Co., Ltd., Bradford, *November 23rd*, 1897.

[We congratulate the indefatigable Mr. Tuke on the steady success he is deservedly achieving. It is just this sort of persistent progress that we wish to see.—ED.]

A CLERGYMAN ON MOTORS.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—I have pleasure in enclosing 8*s.* 1*d.* for the AUTOMOTOR JOURNAL for 12 months from this date, and "Pocket-Book." I am very much interested in the motor-cars, but I greatly regret there is really no vehicle which at present would be suitable for country-people where there is no electric power. The light oils are objectionable, owing to the smell and dangers attending their use.

Until I can find a vehicle which weighs about 3 cwt., and which will carry two or three people at 10 or 12 miles an hour on the level road, I shall not invest in a motor-car. There is such an amount of trouble connected with those now in use, and no little uncertainty as to their working capabilities, that I must only wait. In the meantime, I shall scan your Journal and hope for progress.—Yours very truly,

A. TAIT, D.D., Archdeacon of Tuam.

[Our reverend correspondent may take it from us that a well-designed oil automotor vehicle can be obtained in which there will be no objectionable features, and which can be easily handled and managed by any intelligent stable boy.—ED.]

MR. MAXIM'S MOTOR.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—It was with much interest I read in your last issue the account of Mr. Maxim's new motor and his claims in connection with the same, particularly so as I found I had been working on somewhat similar lines for a tricycle motor. I confess I was considerably disappointed with the arrangement (Mr. Maxim's), as I was looking for a machine that was to strike out on entirely new lines, and I am afraid Mr. Maxim will find he is walking a well-trod path. I saw a diagram of an engine illustrated in one of your contemporaries over a year ago (I believe it was the *Autocar*), which must work on exactly the same cycle as Mr. Maxim's. At the commencement of the stroke the pressure line rose vertically to about 40 lbs. pressure, then moved horizontally for about one-fourth the stroke, then rose again vertically under an explosion to about 100 lbs, and then fell through the ordinary gas-engine expansion curve. I have forgot who the inventor of this engine was, but he will no doubt turn up to claim his rights. Mr. Maxim's method of working his oil-valves by means of mechanically wrought hammers is certainly not a commendable point on a motor-car engine. There will be quite enough hammering action without introducing it artificially. The jolting of the car will not conduce to the steady working of the hammers either. On no point does the motor err on the side of simplicity, and I consider that though it may be a good enough machine to be put into the hands of the expert engineers who are to work the new flying ships, or machines, which are to establish communication with Klondyke, it is not the best engine I have seen to put into the hand of an agricultural labourer.—Yours truly,

J. J.

[Mr. H. S. Maxim will doubtless take note of our correspondent's remarks.—ED.]

The Stanley Cycle Show.—The twenty-first show of cycles, &c., was held during the last few days of November, at the Agricultural Hall, Islington, under the auspices of the Stanley Club. As an exhibition of cycles it was a great success. All the cycling Press has been quite enthusiastic over it. There was also a very good display of tools and machines employed in cycle manufacture. The departure made last year was continued this by including motor-vehicles in the show. But while those vehicles entered were undoubtedly fine pieces of work and well and carefully finished, there was no great improvement noticeable. The Daimler, the Great Horseless Carriage Company, and the Humber Company exhibited their various specialities. The Daimler had seven different kinds of vehicles, all made at the Company's works at Coventry. The only difference between any of them is the car body, the mechanism and framing being alike in all essential features. The Great Horseless Carriage Company had dog-carts, mail phaetons, and wagonettes on view, all, however, fitted with the Daimler motor, also some Bollée voiturettes and De Dion tricycles. The Humber Company exhibited several tandem motor-cycles of the Bollée type and some electrical tricycles. Much ingenuity has been displayed in working out the details of these machines, but it must be confessed that their appearance is not as neat as could be desired. The Burgess Cycle Company showed M. de le Croix's motor-quadricycle, and the Beeston Cycle Company also showed several motor-cycles. It is to be regretted that no motors of purely English design were to be seen, all being of either French or German origin. There was nothing, in fact, calling for extended criticism or description.

President	Sir David Salomons, Bart.
Secretary	Andrew W. Barr, Esq.

SELF-PROPELLED TRAFFIC ASSOCIATION

(INCORPORATED).

NOTICE IS HEREBY GIVEN, that the Second Ordinary General Meeting of the Self-Propelled Traffic Association (Incorporated), will be held at Cannon Street Hotel, London, E.C., on Monday, the 20th day of December, 1897, at 3 p.m.—

1. To receive the Report of the Council.
2. To receive Accounts and Balance Sheet for the year ending 31st December, 1896.
3. To elect Members to fill the vacancies on the Council.
4. To elect an Auditor.
5. To transact the General Business of the Association.

By order,

Andw. W. Barr, *Secretary.*

30, Moorgate Street, London, E.C.,
9th December, 1897.

Liverpool Centre.—Programme for 1898.

1898.	
January 25 ..	Paper: "Some Points in the Design of Automobile Vehicles intended for Heavy Traffic." Mr. Geo. H. Little, Technical Editor of The Automotor and Horseless Vehicle Journal.
February 8 ..	"An Account of our Trials and Experiments, with the Conclusions drawn therefrom." Mr. D. S Simpson and Mr. W. L. Bodman, Joint Authors
February ..	"Steel Springs." (Date and author in abeyance.)
March ..	"Leather Tyres." (Date and author in abeyance.)
March 29 ..	Paper: "Recent Improvements in Accumulators and in their Application to Traction on Common Roads." Mr. J. T. Niblett.
April 19 ..	Paper: "Arrangements for the May Trials." The Honorary Secretary.
May 24–27 ..	Trials of Motor Vehicles for Heavy Traffic.

Inauguration of the Liverpool Winter Session.

The opening of the Winter Session of the Liverpool Centre was inaugurated on the 26th ult., when Mr. Alfred Jones, the well-known Liverpool shipowner and merchant, gave a luncheon at the Exchange Station Hotel, Liverpool, to a large and representative number of merchants. members, and others interested in automobilism, to meet Mr. Worby Beaumont, M.I.C.E., M.I.M.E., who was in the evening to read a paper before the Association, at the Royal Institution, on "Self-Propelled Vehicles."

At the luncheon Mr. A. L. Jones presided, and the company included Sir Gilbert Carter (formerly Governor of Lagos), Mr. Charles M'Arthur, M.P., Mr. Alfred Holt, Mr. G. H. Cox, Mr. John A. Brodie, Mr. E. R. Calthrop, Mr. Harcourt E. Clare (town clerk), Colonel A. H. Holme, Mr. Thomas H. Barker, Mr. Arthur Musker, Mr. E. Shrapnell Smith, Mr. Lawrence Jones, Alderman J. Webster, Mr. W. J. Davey, Mr. Alex. Sinclair, Mr. W. D. Heyne, Captain Rattray. Captain Graham, Mr. Edward H. Cookson. Mr. W. G. S. Alder, Mr. H. Cottrell, Mr. H. L. Spark, Mr. G. W. Neville, Mr. W. W. Wilson, Mr. W. Denton, Mr. J. P. Davies, &c.

After lunch Mr. A. Jones delivered a brief speech, in the course of which, speaking of Liverpool, he said no city could possibly be worse served so far as the means of locomotion were concerned. It was with a feeling of thankfulness that in London they now saw motor-cars running at rates which would pay, and it behoved them to see that they were introduced in Liverpool as soon as possible. Cheap and good locomotion was a matter of vital importance to the port of Liverpool and the surrounding district. It had been said by Mr. Holt that the Manchester Ship Canal was a great misfortune to Lancashire, and there was no doubt it had been, because it was money needlessly spent If they had had some kind of fair dealing on the part of the railways they should never have had the Manchester Canal, and Liverpool would have had a far greater trade than it had. It was most important that Liverpool men should try and get some improved and cheaper way of working the port. They ought not to be satisfied. Manchester was not satisfied until it got what it did not want. Liverpool surely ought not to be satisfied until it got what it did want. A railway could be made to Manchester which could be run at half the rates charged to-day, and leave a handsome profit. The railway companies were not justified in treating Liverpool as they did, and making it pay for their losses in some other directions. He felt that with those enormous ships they were now building delivering cargo at very much lower rates than formerly, they only wanted improved and cheaper transit out of Liverpool, and they might double the trade they had got to-day. The Dock Board were doing all they could according to their intelligence, but they might do more. When he contrasted Liverpool with other ports he always felt sorry to find there was so much done in other places towards getting trade, while they in Liverpool did so much, should he say, to drive it away, certainly not to keep it or get more. The position of matters in Liverpool was sufficient to justify the existence of the Self-Propelled Traffic Association, which was got up with the idea of trying to find out if anything could be done to put their port upon a proper footing. He sincerely hoped their efforts might have the effect of bringing about a better state of things all round.

Mr. Worby Beaumont said that it was only a year since they had been allowed to experiment on the roads, yet he was able to say that with regard to heavy motors there was a promise. As for light motor-vehicles they were now beyond the experimental stage, and were working successfully and economically in this country and in France. They could do what horses could not do. On long journeys the results were excellent One vehicle had run 18,000 kilometres in 10 days, and was in good condition, and after cleaning, started another long journey the following day. The electric cab is running in this country, and promises to be a commercial success, and was likely to become common in a short time. Motor-vans loading to, say, one ton are a practical success. They are now in the postal service for collecting purposes. He thought the Serpollet* system a good one for heavier work, and though little had been done in this country, experiments had been carried out on the Continent. The Scott and Dion motors for heavy loads showed that horses could be dispensed with to advantage. Traction-engines had grown excessively, and got up to 17 tons. This weight on four wheels damaged the roads, and it was a question whether the authorities would allow

* The Serpollet system is fully described in the present number.—Ed.

this. The horse exerted the greatest power, and was most economical for short distances, say about the docks, as it would require an engine of 20 to 25 H.P. to start a load which two horses could work with comparative ease. It is when the motor can do what the horse can't, that it is most economical. When a great traffic offers, trains become necessary; for the most economical system was that which offered the least resistance, as on steel or iron ways, whether plate-way or otherwise. It was possible to carry goods between Liverpool and Manchester at very considerably less than the railways do. It was a question whether it would not be best to combine the motor-vehicle and the light railway system. It was asked what was the best system. There was no best system; for while the electric system was best for cabs or such vehicles in towns, steam was the best under other conditions.

Mr. M'ARTHUR, in proposing a vote of thanks to Mr. Beaumont and Mr. Jones, said it was due to the latter gentleman that they had the opportunity to meet Mr. Beaumont. Mr. Jones, as was well known, was the pioneer in everything that had for its object the progress of the port of Liverpool, and was also the moving spirit in the Self-Propelled Traffic Association. The question that had been treated by Mr. Beaumont was one of the greatest importance to Liverpool and interior districts. A committee of the Chamber of Commerce had gone into the matter of the charges, but had not yet submitted its report. While it was shown that the system of motor-vehicles was successful for the conveyance of light goods and passengers, yet for heavy traffic there seemed little prospect of the possibility of that success. We have still to look to a prepared roadway like Mr. Holt's, with some form of light railway. The suggestions of Mr. Beaumont were practical.

In the evening at the Royal Institution Mr. Worby Beaumont read his paper, an excerpt of which we print below, before a large and representative audience. Among others present were Mr. A. Holt, who took the chair in the absence of Lord Derby, who was prevented from attending through the exceedingly sad death of Lady Lathom (his sister-in-law), Mr. Alfred L. Jones, J.P. (vice-president), Mr. Henry H. West, Mr. Everard R. Calthrop, Mr. Arthur Musker, Mr. Lawrence Jones (hon. solicitor), Admiral Cleveland, Mr. David MacIver, J.P., Mr. Charles Petrie, C.C., Mr. D. H. Simpson (Manchester), Mr. W. L. Bodman (Manchester), Mr. Reginald Bushell, Mr. J. W. Hughes, Mr. Sandbach Parker, Mr. W. S. Patterson, Mr. Robert Gladstone, Mr. William Crosfield, Mr. Shrapnell Smith, and other well-known residents. Among the visitors were Mr. Henry Mozley (Burnley), Mr. Phillipson (Newcastle-on-Tyne), Mr. Chas. Scotter (London), Mr. G. H. Little (AUTOMOTOR), and others.

Letters of apology and regret were received from the Right Hon. Walter H. Long, M.P. (President of the Board of Agriculture), Mr. Charles M'Arthur, M.P., Sir John T. Brunner, Bart., M.P., Sir Thomas Earle, Bart., Mr. Harcourt E. Clare (town clerk), Colonel Morrison, Mr. William Laird, Mr. J. A. F. Aspinall, and Mr. Thos. H. Ismay.

Mr. W. Worby Beaumont on Self-Propelled Road Vehicles, 1896-97.*

IT has often been said that "a job once begun is half done," and it is a great thing to be able to apply this to motor vehicles begun a year ago, especially as "half done" may be taken as implying a perception of completion. It may certainly be said that the attack which has been made on the problem of mechanical propulsion of common road vehicles has materially lessened its problematic character. Much more is now known of what not to do, that which has been done is better appreciated, and many who thought that to make a motor vehicle only required a vehicle and a motor have found out that the production of a satisfactory self-propelled carriage, van, or wagon presents to the mechanical engineer one of the most difficult problems he ever entered upon. They know now that it is not a problem of mere mechanical compilation, but that a great deal of invention is required, and that this inventive skill must be accompanied by a good deal of practical experience.

It is admitted on all hands that satisfactory road vehicles would give rise to great commercial and beneficial changes in our road and street transport methods, and these have been likened to the adventages conferred by railways over stage coaches and wagons for long distances. The world admits that the conceivable change would be of almost inconceivable benefit in many ways, and yet it would ask or seem to expect that this revolution shall be effected by a stroke of the pen of the engineering genius that has taken sixty years to perfect the steam locomotive. Sixty years will not be wanted to effect a vast change in common road transport, and perfection will never be reached, but in a few years mechanical vehicles will give us cheaper, quicker, more convenient, and a cleaner road transport.

A year ago, when, in an address in Liverpool, I advised those who conduct the great heavy street traffic of Liverpool to stick to their horses for the present, I was accused of throwing cold water on motor-carriage expectations. Well, gentlemen, you have stuck to your horses, and, having excellent reasons for doing so, I am sure you do not regret it. I gave that advice because I could see that some were inclined to think that the coming of the motor-wagon was so near an event that the value of horses would decline quickly. It did not, and it will not, because, although the motor cart or lorry may come quickly, and indeed is now a practical success, it cannot, as a thing which has to be manufactured, come in such numbers as to make a sudden revolution. The number required will be so great that the few who are and who may be the successful designers and builders will be unable to meet the demand for a long time. The displacement of the horse will, therefore, not take place so rapidly as to have much or any effect on its value to its present owners.

What, then, has the year shown us, and more especially what has it done with regard to heavy traffic? That which has been accomplished in this country is of great importance, although it has not made much show yet; and as far as the main facts relating to Continental achievements are concerned, I cannot do better than supplement those which have already been presented to you by the energetic committee and honorary secretary of this very energetic northern branch of the Self-Propelled Traffic Association.

Of the British-made vehicles which have been brought out during the year for the heavier classes of work there are:—

1. The steam four-wheeled dust tip-cart, by the Steam Carriage and Wagon Company, Chiswick.
2. The steam van by the Lancashire Steam Motor Company, of Leyland.
3. The steam van by the Liquid Fuel Engineering Company, Cowes.
4. The four-wheeled steam cart, by Messrs. T. Coulthard and Co., Preston.
5. The mineral spirit motor lorry, by the Anglo-French Motor-Carriage Company, Digbeth, Birmingham.
6. The Serpollet steam lorry of the Light Railways Syndicate, for whom it has been constructed by Messrs. Samuelson and Co., Banbury.

Of the Continental vehicles of different types for the heavier kinds of work, the following may be mentioned as having taken part in the severe trials conducted during six days on several routes from Versailles, under the auspices of the Automobile Club of France, in August last:—

7. The Scotte steam omnibus and motor and trail cars (La Société des Chaudières et Voitures a Vapeur, système Scotte). The Scotte omnibus is designed to carry 12 passengers and 14 cwt. of luggage. The motor-wagon is designed to carry about 3 tons and haul about 7 tons. The motor-car, with its trail car or trailing omnibus, is designed to carry and haul 32 passengers and 1 ton of luggage. The motor of each is a 16 H.P. engine.
8. The Weidknecht steam omnibus, designed to carry 30 passengers, the engine being rated as of 34 I.H.P.
9. The De Dietrich lorry, designed to carry 24 cwt. of goods, and driven by a mineral spirit motor of 6½ H.P.
10. The Panhard et Levasser omnibus, designed to carry 10 passengers and 6 cwt. of luggage, and propelled by a 12 H.P. mineral spirit motor.
11. The De Dion et Bouton steam tractor, hauling a char-à-banc carrying 40 passengers, the tractor being fitted with engines rated at 25 H.P. The similar Dion tractor and omnibus, carrying 16 passengers and 10 cwt. of luggage.
12. The Maison Parisienne wagenette propelled by a 9 H.P. nominal spirit motor, and intended to carry 12 passengers and 7 cwt. of luggage.
13. The Serpollet steam omnibus, designed to carry 16 passengers.

Among the motor-carriages or lighter vehicles for three to six persons are the improved Panhard and Levassor carrieges of different forms, those of Peugeot Freres, those of MM. Bollée, those of MM. Gauthier et Wehrle, and a few others, all of which are spirit

* Excerpt from a paper read before the Liverpool Section of the Self-Propelled Traffic Association.

motor-driven vehicles, while in Great Britain we have the improved form of the Panhard and Levassor Daimler motor-vehicle, as made in Coventry, by the British Motor Syndicate and Great Horseless Carriage Company, by the London Motor-Van and Wagon Company, and by Messrs. J. and C. Stirling, of Hamilton. There is also the steam-carriage, made by Messrs. Toward and Phillipson, of Newcastle, the Serpollet steam Victoria, with petroleum fired boiler, and several others which present more or less improvement in detail. In addition, Messrs. Wilkinson and Co., Wigan, are making a steam van, Mr. Jesse Ellis a 3½-ton steam vehicle, and many others, including Messrs. Clarke and Capell, Messrs. Roots and Venables, Messrs. Petter and Boll are working at this problem.

(All the above-mentioned heavy-traffic vehicles were illustrated by means of lantern views and drawings, and were described in detail by Mr. Beaumont, who at the same time reviewed the performance and the results of trials carried out abroad and at home.)

With regard to the various forms of the motor-carriages of the lighter types, it must be pointed out that, with the exception of the Serpollet vehicles, the whole of the conspicuously successful long-distance and high-speed running has been performed, both on the Continent and in this country, by means of motor-vehicles driven by spirit motor, chiefly of the Daimler type. The objections as to vibration and smell have both been so far removed that the users of the recent vehicles have little to complain of, while they are able to accomplish long distances at high speeds, compared with horse travelling, with certainty.

From the description I have given of a number of the heavy motor-vehicles now made at home and abroad, their character, the great progress made, and the early date at which they may become common will have been obvious. With regard now to some of the salient points concerning the progress and future of mechanically-propelled vehicles for the carriage of goods on common roads, I shall take it as proved that the motor goods van for loads up to 10 to 20 cwt. is now a workable and economical thing to employ, and improvements will only be in detail as continued experience may indicate them. Simplification of some of them and improvements in the motor mechanism and its arrangement will be made, just as improvements in railway locomotives and in sewing machines will be made, but there is no need and, indeed, it is useless to wait for these, for they depend on the growth of experience and lapse of time.

Concerning the heavier vehicles there is more to be said. In order to make a new departure a success we must be prepared to bow to expediency so far as the advantages accruing to that departure may be dependent upon changes in our old methods.

One of the chief objects of the employment of heavy motor-vehicles is to avoid the cost on the one hand of horse haulage and, on the other, the objections which attach to the present traction-engines and their incapacity to perform some of the required services. The traction-engine capable of hauling 20 tons on average roads and out of average situations is a heavy machine and is cumbersome, but under many circumstances it will perform work more cheaply than it can be done by horses. These circumstances are not, however, those of the large proportion of town and suburban transport.

Various circumstances have conspired to make the light traction-engine for general purposes an unprofitable one. Weight has increased with power, until now a road locomotive of 10 nominal H.P. will weigh as much as 17 tons in working condition. Now this is over four tons per wheel, and when we remember what happens with stones in a mortar mill under very much less pressure than this it is not difficult to understand that objections accumulate rapidly to heavy loads per axle, more particularly on macadam roads and in wet weather. Now it has been often proposed to carry as much as 10 tons on large motor wagons or lorries, and this means a vehicle weighing at least 14 tons with its full load, that is to say, 3½ tons per wheel, which means very wide wheels, and in any case considerable wear of roads constantly passed. For many reasons it appears desirable the notion of carrying 10 tons per vehicle as an ordinary practice should be given up, and that much more moderate loads should form the ordinary maximum unit. When 10 tons is absolutely necessary as a load, the weight per wheel should be decreased by increasing the number of axles, so as to bring the load down to what may be called the limit of economy of motor-vehicle dead weight, considered with reference to the limit of common road endurance under continuous traffic. The maximum limit of load for common road motor-vehicles may be on economical grounds sooner reached than for horses, because the power of four or six horses for starting heavy loads and for getting them out of awkward places is so great as compared with the power of that size and weight of motor which is for ordinary roads and travelling sufficient for propulsion not only at higher speeds but for almost any length of haul. This proposition would appear to involve a paradox, but a little consideration of practical conditions and limitations will show that the necessity for limiting the weight of load to be carried per vehicle makes the proposition a true one.

The Paris-Versailles trials last August certainly showed that very considerable weights could be carried and hauled up even steep inclines by vehicles such as the Scotte tractors and trains which I have shown and described, the tractor vehicles being much less in weight than anything in the nature of the traction-engines to which we are accustomed.

The tractor vehicles, however, exceed in weight the limit allowed by the 1896 Act, and they were, moreover, loaded much nearer to their ultimate strength, both as to vehicle and propelling machinery, than would be judicious for continuous work. Limited then as we are in this country by that Act, and taking into consideration the limits as to power and road endurance, we are forced to the conclusion that weights considerably less than 10 tons per motor vehicle are advisable, or that a form of vehicle with six or eight wheels all dirigible must be designed.

In moving a vote of thanks to Mr. Worby Beaumont, the chairman, Mr. A. Holt, M.I.C.E., the founder and managing director of that fine fleet of steamers known as the "Blue Funnel Line," said he joined the Association to further investigation, and he was very willing to do anything in his power to the end in view, viz., to secure the style of vehicle wanted for Liverpool work. After years of study he maintained that the plateway system alone would meet their requirements for the Liverpool to Manchester trade. He had too often said that some mechanical feat was impossible of achievement to say such a thing again; nevertheless, although he devoutly hoped he might be wrong, he feared it would be many years before a vehicle for really heavy work was able to conduct their traffic under all conditions. The adhesion of the wheels would not, he felt sure, be sufficient on a greasy, dirty day, upon an incline; they must devise some means other than merely rotating the wheels.

The Volume of Trade passing through Liverpool.

Recently Mr. Shrapnell Smith, the Hon. Sec. of the Liverpool Branch of the S.P.T.A., addressed a letter to the Mersey Docks and Harbour Board asking for statistics of the trade done in Liverpool. In reply the Board furnished the following:—

Statement showing certain Particulars as regards the volume of Foreign Trade passing through the Board's Docks at Liverpool and Birkenhead during each of the three years ending the 1st July, 1896.

Imports.

Year.	Goods paying rates by weight or by measurement, &c., the weight of which it has been possible to estimate.	Goods paying rates per package of the weight of which no estimate can be formed.
	Tons.	Packages.
1894	5,452,000	3,162,000

1896	3,054,000	3,305,000

DESCRIPTION & TRIALS OF THE SERPOLLET LIGHT LOCOMOTIVE.*

FOR some time past a light Serpollet locomotive has been employed on the Cecil Line carrying mails, &c., and has given every satisfaction to the Compagnie de Chemin Fer du Nord. We may mention that this automotor was selected because the amount of traffic in the district did not warrant the employment of the regular train. Some details of the technical arrangements will no doubt be of interest to readers of the AUTOMOTOR.

This Postal Automobile comprises a platform, 2·40 m. by 2·78 m., upon which stands the Serpollet generator, tank, valves, hand feed-pump, &c. There is next to this a compartment for passengers, &c., 3·07 m. by 2·50 m. It can carry 10 passengers, the total weight (loaded) being 17·65 tons The weight on the driving axle is 10·8 tons, and the tractive effort 2,182 lbs. The diameter of the wheels is 3 feet 1½ inches.

The boiler which produces the steam, and which is the distinguishing feature of this system, is illustrated in Fig. 1. As will be seen, it is vertical, and consists of 44 tubes, placed in groups of four; the eight lower tubes are of a circular section, as are also the four higher ones. The 32 intermediate tubes are of U section, and are arranged in eight groups. The tubes are about 12 mm. thick, and when pressed to the U or kidney shape the internal tubulure is about 3 mm. wide. After being arranged in groups they are joined up "in series" by means of screwed unions, much in the same way as is adopted in the Belleville boiler. Before being passed for service each tube has to stand a test pressure of 1,500 lbs. per square inch. There is thus a large factor of safety. The dimensions of the boiler are:—Height, 1·14 m.; breadth, ·68 m.; and width, 1·77 m. The heating surface is 11·32 sq. m. and the grate area 46 square decimetres; the weight of the boiler is 2,880 kilos.

Two suction and feed pumps, worked by the motor-axle, inject water from a tank of 650 litres in capacity, placed behind the driving-axle, into the lower part of the boiler, where heating and evaporation take place; the steam thus produced being superheated in the middle groups and attaining in the higher part a temperature of 350° C., passes into the distribution valves of the motor.

At the outset this ingenious system of instantaneous evaporation was subjected to various criticisms; the engineers feared on one hand the sudden re-cooling of the boiler, on the other the force of the fire.

The improvements carried out in this system have caused difficulties and inconveniences to disappear. A pyrometer, the dial of which is under the eyes of the driver, indicates the real state of the superheat, and by this means he can accordingly regulate his fire and speed, and the use of a small extra feed which works during stoppages causes an incessant circulation in the tubes of a certain quantity of water, which is a protection to the boiler from the heat of the fire. The cylinders are placed longitudinally and in the middle of the framing of the vehicle; they are of 18 cm. diameter by 15 cm. stroke. As will be seen from the accompanying illustration, Fig. 2, motion is transmitted to the driving-axle by pinions, and the first motion shaft also works a feed pump. On the driving-axle is the compensating gear. In contradistinction to ordinary water-space or water-tube boilers, boilers of the "instantaneous generation" type frequently contain no water whatever. Speed, therefore, is regulated, not by liberating more or less steam from a reservoir of pressure but by direct control of the amount of water admitted into the boiler. When a stoppage is necessary, the feed is stopped and the boiler may be devoid of either water or steam. In order to start, half-a-dozen strokes of the hand feed-pump are sufficient to inject enough water to provide a working pressure when the automatic pump continues the supply and the speed is regulated by the "pass-valve." This valve is interposed between the pumps and the boiler, and allows the water delivered by the pumps to pass either:—

(*a*) Entirely to the boiler, for maximum pressure;
(*b*) Partly to the boiler and partly back to the feed-tank, for intermediate pressures;
(*c*) Entirely to the feed-tank, for cessation of motion.

The speed is, therefore, capable of regulation to a nicety by merely turning a small hand-wheel. After extended trial, this screw-valve is now being replaced by a balance-valve, having the spring attached to a slide on the lever-arm which regulates the pressure on the valve. Between the boiler and the engines, on the main steam-pipe, an ordinary stop-valve has been introduced. This new arrangement permits of the pressure being varied according to the requirements of the route for, by moving the slide along the lever of the balance-valve, the feed-water returned to the tank whenever the pressure corresponding with the position of the slide tends to be exceeded. The approximate pressure required is thus maintained in the boiler. The stop-valve is used to shut off steam during stoppages and reduced speeds, or to avoid using the brake, exactly as in a locomotive. So far the performance of this Post Office automobile and mail wagon has been most satisfactory. The speed, of course, varies with the gradients. On a gradient of 13 mm. the speed is 37·5 kilometres per hour, but on the level as much as 70 kilometres has been attained; the consumption of small coal is about 2·25 kilos. per kilometre.

FIG. 1.—SERPOLLET BOILER.

In Paris some trials have, during the past year, been made with the Serpollet carriages, in order to determine the speed, power, coal and water consumption. We give the results here as there is no reason why this system should not be adopted in many English towns. The trials were made on a course from the Place de la République to the Place du Chateau-Rouge (above the Barbès Boulevard), which is almost a continuous ascent; the distance between these two places is about 2,600 metres, and the altitude difference about 30 metres, which gives a slope on an average of $\frac{30{,}000}{2{,}600} = 11{\cdot}5$ mm. per metre.

From these experiments made by the omnibus company, one can estimate about 13·5 kilos. as the resistance per ton of these carriages at the stopping places. On a slope of 11·5 mm. this resistance becomes equal to $13{\cdot}5 + 11{\cdot}5 = 25$ kilos. per ton. The weight of these carriages, properly laden, is a little over 16 tons; their average resistance in motion on the considered course is about $16 \times 25 = 400$ kilos.

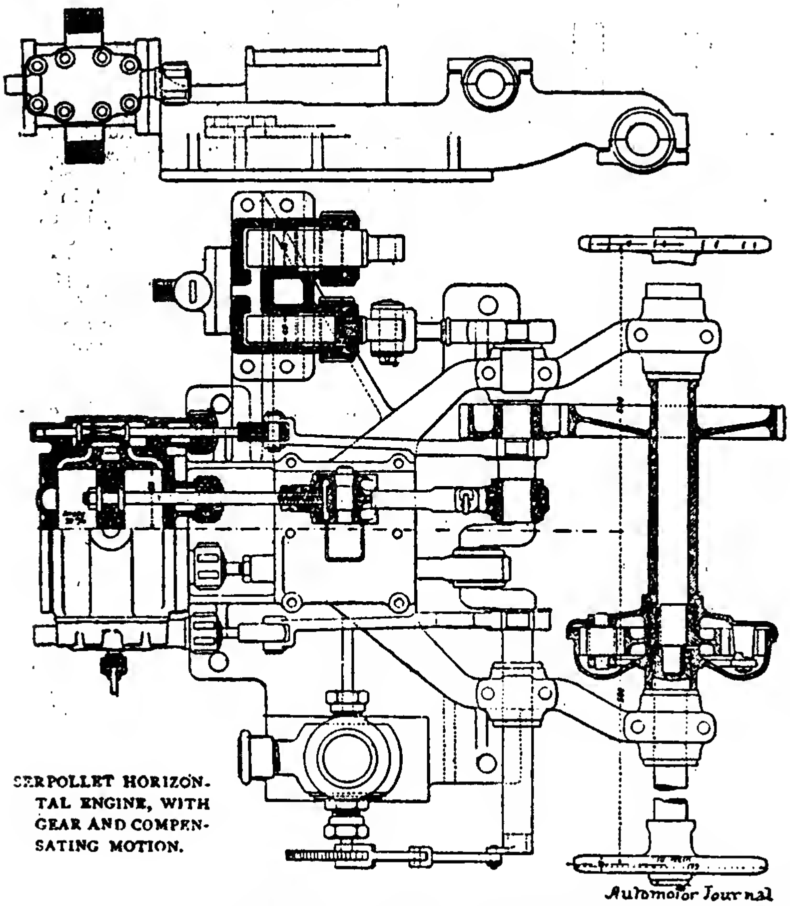
* This article is published at the request of numerous subscribers.—ED.

On the other hand, the average speed (deducting stoppages) is from 10 to 12 kilometres per hour, otherwise about 3 m. per second ; the effective work done by the motor is thus :—

$$400 \text{ kilos.} \times 3 \text{ m.} = 1{,}200 \text{ kilogrammetres, or } \frac{1{,}200}{75} = 16 \text{ H.P.}$$

On one car the quantity of water was measured for three separate cut-offs of the stroke, viz., at 31, 50, and 66 per cent. The consumption of water is easily ascertained by reading the gauge on the feed tank. It was in the three cases 27, 30, and 33 litres for the journey. The consumption of water per effective H.P. is then in the three cases :—

$$\frac{27}{16} = 1{\cdot}69 \text{ litre.}$$
$$\frac{30}{16} = 1{\cdot}87 \text{ litre.}$$
$$\frac{33}{16} = 2{\cdot}06 \text{ litre.}$$



SERPOLLET HORIZONTAL ENGINE, WITH GEAR AND COMPENSATING MOTION.

Automotor Journal

Each time the journey was made in 17 or 18 minutes, in which the stoppages took up about three or four minutes; the real time, therefore, occupied was exactly 15 minutes; the consumpt per H.P. hour would be thus :—

$1{\cdot}69 \times 4 = 6{\cdot}76$ kilos. for the journey at 31 % cut off.
$1{\cdot}87 \times 4 = 7{\cdot}48$ kilos. for the journey at 50 % cut off.
$2{\cdot}06 \times 4 = 8{\cdot}24$ kilos. for the journey at 66 % cut off.

The temperature of the steam was the same in all three cases, from 230° C. to 240° C., and the superheat on an average about 70° C.

Two experiments carried out on the following day, on two other carriages, gave the following results :—

First journey at 31 % cut off—

Average pressure of the boiler	6 kilos.
Temperature of the steam	350° C.
Superheat of the steam	190° C.
Consumpt of water	24 litres.
Consumpt per H.P. hour	6 litres.

Second journey at 50 % cut off—

Average pressure of the boiler	7 kilos.
Temperature of the steam	210° C.
Superheat of the steam	40° C.
Consumpt of water	50 litres.
Consumpt per H.P. hour	12·5 litres.

These are remarkable results for engines of such a small power, working with the customary expansion of only two volumes and without condensation ; it is evidently due to the use of superheat.

The temperature of the feed water in these experiments was, on an average, from 50° C. to 60° C.

If the mean consumpt per kilometre is found, it will be seen that in the first experiments it has been raised to :—

$$\frac{27}{2{\cdot}6} = 10{\cdot}4 \text{ kilos.}$$
$$\frac{30}{2{\cdot}6} = 11{\cdot}5 \text{ kilos.}$$
$$\frac{33}{2{\cdot}6} = 12{\cdot}7 \text{ kilos.}$$

If on an average slope of 11 mm., the resistance of the carriage is only 15·5 kilos. − 11·5 kilos. = 4 kilos. per ton, in place of 26 kilos., the consumpt would be only $\frac{4}{26}$ of the preceding figures, or respectively 1·6 kilos., 1·8 kilos., and 2 kilos.

The average consumpt for the whole journey would be :—

$$\frac{10{\cdot}4 + 1{\cdot}6}{2} = 6 \text{ kilos. for the journey at 31 \% cut off.}$$
$$\frac{11{\cdot}5 + 1{\cdot}8}{2} = 6{\cdot}7 \text{ kilos. for the journey at 50 \% cut off.}$$
$$\frac{12{\cdot}7 + 2}{2} = 7{\cdot}2 \text{ kilos. for the journey at 66 \% cut off.}$$

In the last two experiments this consumpt falls to 5·3 kilos. for the first, and rises to one litre for the second.

Other experiments made on the whole journey from Porte Clignancourt to the Bastille, distance 11·2 kilometres, give the following results :—

Journey at 50 % cut off—

Average pressure in the generator, 7 kilos.
Consumpt of water, 92 litres, or, per kilometre, $\frac{92}{11{\cdot}2} = 8{\cdot}2$ litres.

The temperature was not taken as the carriage was not provided with a pyrometer.

A second experiment on another engine going over the same course gave a kilometric outlay of 12·5 litres.

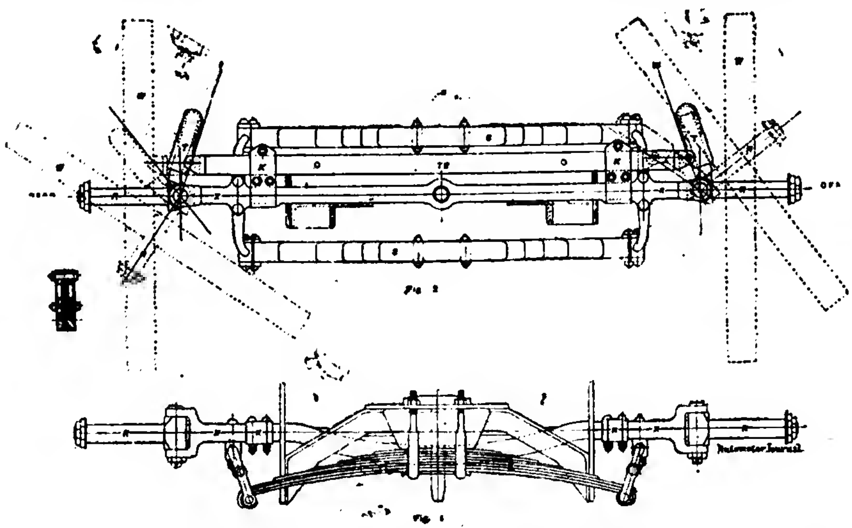
Lastly, if the steam is not all superheated, or if the fire has not been lighted early enough, or during the journey if the engine-driver lets the fire get low, or injects too great a quantity of water into the boiler, the consumption will be raised to 20 litres and more per kilometre. But usually the engine-driver maintains a temperature of about 250° C. of steam, which after a little practice is very easy to do; the consumpt per kilometre is only 6·5 litres. This figure for the consumption of steam can be compared with carriages on the electric tramway, worked on the trolley system or by accumulators.

In the trolley system the average energy absorbed by a kilometre carriage for an automobile to seat 50 is a 3 H.P., corresponding to an outlay of steam of about 16 kilos.

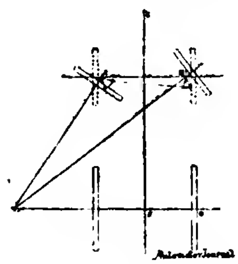
For carriages worked by accumulators the energy is equal to a 3 H.P., corresponding to an outlay of steam of 24 to 25 kilos.

DAVIS'S STEERING GEAR.

NOT a little ingenuity, misplaced and otherwise, has been exhibited by various inventors of late years in designing steering gears for automotor vehicles. But it cannot be said that the principles underlying the matter are as well understood as is desirable. In ordinary four-wheeled vehicles in which the axle of the fore wheels rotates upon a pin placed in the longitudinal axis, it is necessary, in order to maintain a straight course, that the two wheel axles shall be parallel; and in order to go in a curved path that the two axles form the ends of radii of the common centre of curvature. In practice, especially for heavy vehicles on rough roads, this means erratic steering, and a straight course can only be maintained by aid of a long pole or shafts projecting in front of the vehicle and which not infrequently forms an effective but unnecessary battering ram. There are few things more unwelcome or unpleasant when one is,



say, driving out to dinner through a crowded thoroughfare than to have the pole of a bus projected through the back of the vehicle and prodding one in the ribs. It is at such times that one longs for the suppression of all horse-drawn vehicles. Another objection to the accepted mode of steering is that it practically gives the vehicle but three points of support, and this not infrequently leads to a capsize through want of stability. If instead of using a rotating fore axle a rigid transverse axle be employed and means be given so as to permit the wheels at the ends to rotate in a vertical plane, not only is the steering much simpler but the weight is better distributed. In this case, how-



ever, the two wheels must make some angle with each other, and this angle will vary as the ratio of the beam or distance between the two fore wheels and the radius of the curve. In fact, each wheel is tangential to its own radius. This is clearly seen by a reference to the accompanying figures. Mr. Davis has ingeniously worked out the mechanical details of these principles in the steering gear shown in Figs. 1 and 2, in which Fig. 1 is an elevation of the improved gear, and Fig. 2 a plan of the same looking on the top side of the springs and axle. In Fig. 1, X, X is the axletree, having forked ends, to which are attached the jointed arms, R, R, on which the wheels, W, W, when in motion turn. With these arms are combined, in one forging, the tiller heads, T, T, fitted with sleeve pieces coupled to the ends of the movable tiller bar, T, B, which is carried in the clip guides, K, K, fixed at both ends of the axletree, X, X, the springs, S, S, supporting the fore body of the car being located on either side of the axletree and carried by it as shown. Motion may be given to the bar, T, B, by any kind of hand gear preferred by the carriage builder. Fig. 3 is a diagrammatic plan of a four-wheeled vehicle with the trailing axle, D, D, fixed, the two steering wheels being pivoted on the ends of the leading axle at A and B, as previously shown in Figs. 1 and 2.

Royal Agricultural Society Motor-Car Competition.—In connection with the Birmingham Show to be held in June next, the Royal Agricultural Society offer a first prize of £100, and a second of £50, for self-moving vehicles for light loads, and prizes of equal amount for similar vehicles for heavy loads. Light load vehicles will include such as would take the place of light spring carts for carrying loads up to one ton, exclusive of the weight of the vehicle; the heavy load class will be for vehicles capable of carrying three tons, exclusive of their own weight. The competitions are for vehicles carrying their loads, not drawing them. In the case of equal merit in either class the prize money will be divided, or in case of insufficient merit any prize may be withheld. All vehicles are to be propelled exclusively by mechanical means, and, in the case of oil-engines, any such oil may be used as is allowed by the regulations as to petroleum made and circulated by the Home Secretary under Section 5 of the Locomotives on Highways Act, 1896. The design is left to the manufacturer, but he must conform to the Act. Trials will be made of the competing vehicles carrying a declared weight for an ordinary load over a distance not less than 25 miles out and 25 miles return. During the run the consumption of fuel, water, &c., will be carefully noted. The maximum speed to be in accordance with the regulations of the Local Government Board. Such further trials will be made as the judges may consider necessary to test the efficiency of the vehicles ascending or descending hills or otherwise. The points to which the special attention of the judges will be called are:—Due regard to the convenience of the public; ease of handling, with special reference to stopping, starting, and steering; economy in working, including attendance; price; simplicity; strength of design; weight of vehicle; in the case of oil engines, density and high flashing point of the oil used. The trials will take place early in June, 1898, in a locality to be subsequently fixed. Shedding accommodation will be provided by the Society, free of charge, for the trials and for the exhibition of the competing vehicles in the Society's showyard at Four Oaks Park, Birmingham, from June 18th to 24th, 1898; but each competitor must himself arrange for the staff and appliances necessary for showing his vehicle at work in the showyard, and for its delivery to the showyard. The entries for these prizes must be made on or before Friday, April 1st, 1898, and must be accompanied by a deposit of £10 for each entry. Such deposit will be forfeited if the machine is not submitted for competition at the time appointed for the trials, and is not exhibited at the Birmingham meeting.

Motor-Cars for Northumberland.—For some time there has been an agitation to obtain a short railway between Cramlington and Newsham, Northumberland, which has been very much opposed, and now, apparently, abandoned. The Northumbrians, however, are not to be beaten, and with the aid of Mr. John Philipson, J.P., of the well-known firm of Atkinson and Philipson, of Newcastle-on-Tyne, the requirements of the neighbourhood are likely to be satisfied during the forthcoming year by the introduction of steam motor-cars built by this firm and Messrs. Toward jointly. Recently the qualities of their No. 4 steam motor-car were tested, with the most satisfactory results. The roads were very bad, but there was no difficulty in getting a regular speed of about 12 miles an hour without the least vibration. The car, which is of a wagonette shape, carries six persons, the seat in front carrying two. The fuel is coke, and during a drive of 12 miles only about 6 or 7 lbs. were burned. We understand that very shortly contracts can be arranged for the supply of these motor-cars.

THE FAURE-KING TRACTION CELL.

This cell is being so largely used for automotor vehicles that the following tests made by Mr. E. Wilson will be of interest. Speaking on Mr. L. Epstein's valuable paper * at the Institution of Electrical Engineers, Mr. Wilson said about six months ago he had carried out a series of experiments upon traction type cells in the Siemens' Laboratory, King's College, for the purpose of a small work entitled "Electrical Traction." Those experiments were given in full in the book, and he had extracted the results in the table below, which

—	Number of Test. 5	6	7
	Discharge.	Charge.	Discharge.
Volts, initial without current	—	—	2·18
Volts, initial with current ..	2·04	2·135	2·02
Volts, final with current ..	1·85	2·6	1·85
Ampères, constant at ..	15	17·8	14·9
Total time of discharge ..	5 h. 20 m.	5 h. 30 m.	5 h. 15 m.
Ampère-hours	80	97·9	78·2
Watt-hours	157	228	155
Quantity efficiency	82	—	89·7
Work efficiency	68·8	—	76·1

refer to an Electrical Power Storage Company's Faure-King traction type 5-plate cell. The cell was fully charged when delivered. The two positive plates measured each 7¼ inches by 8 inches, and had a thickness of ¼ inch, not including the perforated envelope in which they are placed. They weighed, with lug, when just taken out of the acid, 7 lbs. 7 ozs. The total weight of the cell in ebonite box and acid was 21 lbs. 2 ozs. The special gravity of the acid in the fully-charged cell was 1·275. Tests Nos. 5 and 7 in the table showed for a net drop of about 0·2 volt, with current passing, a work efficiency of about 72 per cent. It was to be clearly understood that these tests had been made upon new cells, and that therefore no conclusions could be drawn as to the life of such plates; and further, tests made upon isolated cells like these might not represent the average results which would be obtained from many. It was interesting to see what weight of these storage cells would fulfil the conditions put down by Mr. Epstein. Taking his lower rate of discharge at 2,208 watts for five hours, the watt hours would be 11,040.

The Faure-King type cell just referred to, when working under the conditions given in the table, gave 156 watt hours. Therefore, $\frac{156}{21} = 7{\cdot}43$ was the work in watt hours per lb. of total weight of cell. Dividing this into 11,040 should give the total weight of a battery of these cells to fulfil the conditions put down $\frac{11{,}040}{7{\cdot}43} = 1{,}490$ lbs., as against Mr. Epstein's 1,000. This made no allowance for diminished capacity after continued working, if such existed in this cell. The number of such cells would be $\frac{1{,}490}{21} = 71$, and since 2·6 volts were required for the fully charging of the cell at the rate given in the table, the total charging volts would be 2·6 × 71 = 185, if the cells be kept in series. The number (71 cells) just given could be considerably reduced if the capacity be increased, and still give currents convenient to deal with in motor and controlling apparatus. This was important, since the weight of an equivalent battery, so far as work is concerned, would come smaller. Taking the 9-plate instead of the 5-plate Faure-King cell, it was capable of discharging 150 ampère hours at 30 ampères, the time, as before, being five hours. The weight was 35 lbs., complete with acid, as against 21 lbs. in the 5-plate cell. From these figures the watt hours per lb. $= \frac{300}{35} = 8{\cdot}57$, as against 7·43; also $\frac{11{,}040}{8{\cdot}57} = 1{,}290$ lbs., as against Mr. Epstein's 1,000. The number of such cells would be $\frac{1{,}290}{35} = 37$, and, allowing 2·6 each, the voltage would be 96 if the cells be charged in series. Under these conditions, then, 1,000, as given by Mr. Epstein, seemed low, but he might have assumed different conditions of working. It was premature to discuss which type of cell will eventually survive for traction purposes. The cell of the future must be capable of being over-discharged without serious injury.

PROCEEDINGS OF TECHNICAL SOCIETIES.

Mechanical Propulsion on Canals *—(*continued*).

Propulsion by Screws.—In America in 1871 competition was invited for introducing upon the canals in the State of New York some other method of haulage than by animal power.

The first designs presented were intended to overcome the wave, which it was thought a speed of three miles an hour would cause; but this difficulty, as had already been shown some years before by Pole's experiments, was more apparent than real at that speed, because a wave of sufficient height to be detrimental is caused rather by the speed exceeding three miles an hour than by the actual nature of the machinery used for propulsion. Boats carrying light freight and passengers, and running at six miles an hour, do cause injury to the banks.

The principal changes made since that time have been connected with the improvement of some of the details of the boats, which have resulted in the present canal steamers, and also in the use of these steamers for conveying through the canal one, three, or five ordinary canal boats fully laden. The steamer usually pushes one boat in front of it, and tows two other boats behind it, which are kept together in the same way as the coupled horse boats at present in use. In addition to its fuel the steamer carries 180 tons of cargo; the canal boats carry 250 tons each. In the coupled horse boats, one boat is directly behind the other, their bow and stern being in actual contact. They are coupled by ropes running from the stern of the forward boat, through blocks on each side of the rear boat, and returning to a steering wheel on the forward boat. The ropes are not connected with the rudder of the rear boat, which is left to swing freely, and the boats are steered by using the whole rear boat as a rudder. The standard steam canal boats are 18 feet wide and 90 feet long. The engine commonly in use was designed by Gordon W. Hall, and is generally known as the Hall engine; another engine designed by the Pound Manufacturing Company has been placed upon a number of boats. Both these engines are simple condensing engines, with cylinders of 12 to 14 inches diameter and 16 inches stroke. They have adjustable cut-off gear, feed-water heaters, and surface-condensers. The feed and air pumps are worked by a single beam, which is usually actuated by an eccentric on the crank shaft, but sometimes by the cross-head. The arrangement for securing circulation of the water for the surface-condenser is peculiar: by the motion of the boat and of the screw the circulating water is forced up, without pumping, through the opening in the bottom of the condenser, and out at the stern. In a modified form this plan is adopted in some of the torpedo boats and destroyers in the navies of this and other countries.

Aire and Calder Navigation.—The method of propulsion in use on the Erie Canal is not unlike that which up till lately was in vogue on the Aire and Calder Navigation, and has proved so successful. Here a steam tug in the rear propelled in front of it a train of 11 boats, each carrying about 40 tons. The boats are 20 feet long, 16 feet wide, and 7½ feet deep. A tender or dummy boat was attached to the front of the train, in order to make a stem, because the vessels of the train themselves are not strictly boats, but merely iron boxes for stowing cargo in. It was supposed that by having the tug behind the train, instead of in front, greater control could be exercised over the boats in steering them. The author has been informed, however, that this plan has been discontinued, and that at the present time the tug is placed in front of the train. The boats are threaded together by means of wire rope controlled by two cylinders, which are self-acting and are under the charge of the steersman. By lengthening or shortening the ropes on each side of the train it can be guided in any curve, while the several vessels composing it are left to rise and fall separately according to any little variation of

* Abstract of paper read by Mr. Leslie Robinson at the Institution of Mechanical Engineers.

head-line; the train is not bound rigidly in any way. Side-buffers are attached to the ends of each boat, which have a tendency to bring them back again into a straight line in the event of any slight disorganisation caused by wind and water; the train and its direction are under the full control of the steersman. This plan Mr. Bartholomew considers could not be introduced on many of the canals in England, unless the locks were made longer; but he would prefer inclined planes for getting from one level to another. The locks on the Aire and Calder Navigation are long enough to admit one of these trains at a time, so that after having been made up they do not need to be uncoupled until they arrive at their destination. The cost of conveying mineral traffic by these boat trains is low; it will be dealt with subsequently.

Leeds and Liverpool Canal.—Tugs propelled by screws are in use also upon the Leeds and Liverpool Canal, of which the cross-section is at present small, and is now being enlarged at considerable expense. Some years ago Mr. William Wilkinson, of Wigan, suggested utilising ordinary barges as tugs, by putting in small engines to drive a screw propeller as large as could be made available without too high a percentage of positive slip; and he proposed, further, to make each tug carry a paying cargo. In conjunction with Mr. Charles White, the engineer of the canal, he fitted up one of the barges with engines. When tried, it was found that it was able to tow two others at a speed of two miles an hour; in parts of the canal where the depth is greater the speed rose to 2¾ miles an hour; and under similar conditions, with only one barge in tow, as high a speed as 3½ miles an hour has been attained, but then a rolling wave was set up which caused injury to the banks, thereby confirming Dr. Pole's observations upon the Ashby-de-la-Zouch Canal. The results proved so satisfactory that some 40 more barges have since been fitted up for the same canal by Mr. Wilkinson's firm. The form of propeller adopted was arrived at by an exhaustive series of experiments, and its best results are obtained in shallow water.

Engines.—In conjunction with the Leeds and Liverpool Canal Company experiments have also been made by Mr. Wilkinson, with the object of finding out the best form of engines to use in the barges. The following eight kinds have been tried:—(1) Simple diagonal with two cylinders, and (2) compound ditto jet-condensing, and (3) compound ditto surface-condensing; (4) compound with four cylinders, two high pressure and two low, surface-condensing; and (5) ditto jet-condensing; (6) compound inverted vertical two-cylinder tandem, high pressure over low, surface-condensing; (7) compound with two cylinders side by side, non-condensing; and (8) compound diagonal with four cylinders, two high pressure and two low, non-condensing, with 140 lbs. steam, and cranks at right angles. The two last, Nos. 7 and 8, give the best results. With No. 8, which is now the standard engine on the canal, the author is informed that the following performance is obtained. The tug, 62 feet long by 13 feet wide and with 3¼ feet draught, carries 28 to 30 tons of cargo besides her machinery and fuel, and tows two barges 62 feet long by 14 feet wide, each carrying 36 to 40 tons, from Liverpool to Leeds, a distance of 128 miles with 97 locks, on a consumption of 43 lbs. of good gas coke per mile, locks included: which is equal to 0·39 lbs. of coke per ton-mile, assuming the boats to be fully loaded. Including loading and discharging, the double trip of 256 miles total is made in six days. It is stated by Sir William Bailey that these steamers have conduced much to the punctuality and regularity of working on the canal, and that in comparison with horse towage they have accelerated the speed some 40 per cent.

Upon some of the canals in the Netherlands small screw boats are fitted with petroleum motors, constructed by Van Rennes of Utrecht, which drive the screws through belting.

On the Bourgogne Canal a trial is being made of a small screw driven electrically, and fixed in the rudder of the boat. A large steel box carrying the motor and screw is attached to the stock of the rudder; the box displaces a volume of water more than equal to its own weight, and is thus capable of floating alone upon the canal. It has a total length from front to back of 8 feet 2 inches, a height of about 5 feet 10 inches, and a width of about 1 foot 5 inches. This width is continued only for a distance of about 5 feet 10 inches backwards from the front end; after that it is cut away to allow of a freer run aft. The motor is fixed in the box upon a foundation plate secured to the bottom, and its shaft is connected direct to the screw. The entire box, containing motor and screw, weighs about 15¾ cwts., and floats with a draught of from 4 feet 1¼ inches to 4 feet 3¾ inches.

Hauling upon a Submerged Chain or Wire Rope.—A favourite means of traction, especially in France and Belgium, consists in hauling upon a chain or wire rope, fixed at each end, and laid along the bed of a canal or canalised river; but it is only on the most frequented canals that it can be advantageously applied, and only in a certain number of reaches of great length. It is extensively used in the tunnels upon the canals in the North of France. To render it remunerative there must be a considerable amount of traffic, and the tolls should be somewhat lower than those for towing by horses; also the reaches should be long enough for the trains of boats to regain the time lost in locks. According to M. Derôme, with chain haulage on a much frequented canal the average speed of a train of four boats cannot practically exceed 2¼ miles per hour. That of a boat drawn by horses is usually 1¼ mile per hour. Haulage is superior to tugs only when there is any current to contend against; its advantage diminishes as the velocity of the opposing current decreases.

Hauling on a submerged chain is done by means of two grooved drums, one behind the other in the line of the chain with their axes parallel to each other and about 10 feet apart, round each of which the chain is generally wound about four half turns, making four turns round the pair. As far as the preservation of the chain is concerned, the plan is defective. If the grooves in the drums are not absolutely equal in diameter the chain cannot help slipping, and abnormal strains then arise in the intermediate lengths, often exceeding the tractive force on the stretch ahead upon which the boat is hauling itself. The chain, moreover, is bent as many as eight times during its four half turns round the drums; when working in sandy or muddy water the alternate bending and straightening is highly detrimental to its durability. The necessity for one boat throwing the chain off when meeting another is also a great objection, as this is not easy to do, and causes a considerable loss of time. It has, however, been got over to a certain extent in M. de Bovet's magnetic tow boat "Ampère," now in use on the lower Seine, where the chain passes over only one pulley, which is magnetised, and thus causes it to adhere. The wetting of the chain even by soapy water does not cause a loss of more than 10 per cent. of the tractive power. Up to the present this boat has been successful; the chain is used only for going up the river; on the downward journey the boat is propelled by an ordinary screw. In order to avoid having to throw the chain off when meeting another boat, it has been proposed to use two chains, which, however, would necessitate widening the bottom of the canal in order to prevent them from getting entangled, and even then the danger would still exist in curves. In 1860 some experiments were made on the Grand Canal in Ireland with chain haulage, but it was found impracticable. Although it has been so successful on the Continent, its advantages have not been sufficiently great to lead to its adoption in this country.

Upon the Rhine a wire rope is used instead of a chain ("Proceedings, 1869," p. 240). The rope is laid in the bed of the channel, and is taken up over a wheel at the bows, passed round a clip drum, and then dropped astern. Some experiments with a wire rope were made by Sir Leader Williams on the Bridgewater Canal; but where there is much traffic in the opposite direction, and many bends in the canal, the wire-rope plan is found to be practically unworkable. Cable towing was also tried upon the Erie Canal in the United States. The first cable of 34 miles length was laid down in 1872, and in 1879 there were over 80 miles of it; but it was abandoned after ten years' trial.

Electric Haulage.—Electric haulage on a chain has lately been started upon the Bourgogne Canal, and has given complete satisfaction up to the present time. It was designed by M. Galliot, Ingénieur des Ponts et Chaussées, under the direction of M. Fontaine, chief engineer of the Bourgogne Canal, and was approved by the Minister of Public Works on February 8th, 1893; the work was immediately begun, and was finished on July 15th following. The reach of canal upon which the system has been applied is 3¾ miles long, and includes a little over two miles through a tunnel; the width of waterway is about 23 feet in the open and about 20 feet in the tunnel, while the depth varies from 7 feet 4½ inches to 7 feet 10½ inches. From 1867 to 1883 barges were towed by a steam tug hauling on a submerged chain; the plan worked well, but was dear, the cost of maintenance being high. In 1888, the old tug boats being no longer serviceable, it was decided to utilise the waterfall at the canal locks for driving turbines to generate electricity, and to work this reach electrically. The ground having been surveyed, it was decided to make a fall of 23 feet at Pouilly at the Seine end, and another of 26¼ feet at Escommes at the Saône end. The available water power at Pouilly is 20·7 H.P., and at Escommes 11·8 H.P., making a total of 32½ H.P. Two dynamos are used, which are shunt-wound Gramme machines, connected in series: that at Pouilly is constructed to supply a normal current of 30 ampères at 370 volts, and the other at Escommes furnishes 30 ampères at 280 volts. A conducting wire running along the canal bank joins two opposite poles of the machines; and from each of the two remaining poles a separate wire runs along the same bank parallel to the first wire and below it; by means of the two lower wires the current is conveyed to the motor. When the turbines are running at their normal speed, the total electromotive force is 370 + 280 = 650 volts; the resulting current does not generally reach 30 ampères, but varies between 12 and 25 ampères according to the cargo towed; for a current of 25 ampères the loss of power is 180 volts. The motor is capable of absorbing a maximum of 18½ H.P.; it is rarely, however, that such a high power is required. The mode of connection by the wires presents the advantage that the length of conductor traversed by the current remains always the same, on whatever part of its journey the tug boat may be. The switchboard on the tug has a rheostat of 180 ohms for admitting the current gradually to the motor. The governor regulating the admission of water to the turbines is worked electrically; it allows a variation in voltage of only 10 per cent. when a tug is starting, and normally a variation of only 2½ per cent. A battery of accumulators is connected in parallel with the conducting wire, and works simultaneously with the dynamos; the connection is continuous, so that the accumulators act as equalisers. The battery working alone is sufficient for two journeys in each direction; it is placed in the collar of the resident engineer's house. The accumulators have been found, however, to be of but little use; and M. Galliot states that, if the work were to be done over again, he should dispense with them, and should also use series-wound dynamos, instead of shunt-wound as at present. The total length of circuit traversed by the current being about 7½ miles, the resistance is 3·9 ohms. In ordinary working at 600 volts with a current of 20 ampères the efficiency is 87 per cent. The three wires of the line are so arranged as to occupy in section the corners of an isosceles triangle 3·9 inches high, the two lower wires being those along which the current travels to and from the motor. For keeping the wires in their required position, insulators of a special form are used. The line so constituted forms an open circuit; to close the circuit, it is only necessary to place the two lower wires in contact with the poles of the motor, which is done by means of two trolleys carried by the boat. As on American tramways, the trolleys are composed of two long jointed arms, each terminating in a small roller, which travels along the conductor on the bank of the canal, and conveys the current to the motor leads that run through the arms. At the end of the arms of the trolleys the conductors are connected to the switchboard, and thence to the poles of the motor. The latter is a series-wound Gramme machine, which on a brake trial at 900 revs. per minute, with 30 ampères and 550 volts, gave 19 brake H.P.; the mechanical efficiency was 85 per cent. The motor receives a greater or less supply of power in proportion to the trains it has to tow; it works well with different cargoes in tow, and is remarkably free from sparking. It is connected to the chain drum by means of belting; the pulley of the motor is 11·8 inches diameter, and the fly-wheel on the chain drum 5 feet 10¼ inches, or six times the pulley. The boat is geared for two nominal speeds of 1·79 and 3·13 miles per hour; the actual speed of course varies largely with the weight of cargo towed. The tug is 49 feet 2¼ inches long, 10 feet 6 inches wide, and 3 feet 11¼ inches deep, with a draught of 1 foot 5¾ inches. Fore and aft she is covered with fluted sheet-iron; and a length of 26 feet 3 inches amidships carries a cabin of thin sheet-iron to protect the machinery from the weather. In order to prevent the chain from bespattering the boat, it is entirely enclosed in a U-shaped trough, which is covered by a half-round lid of thin sheet-iron. The chain enters and leaves the boat through two holes similar to those on river steam-tugs. There are two rudders, one at each end, and each connected to a wheel placed at the opposite end, so that the boat can be steered from the forward end both up stream and down stream. In the tunnel the boat is lighted by electricity. The total cost of the arrangement was about £5,400, including £400 for the accumulators and £200 spent on unsuccessful trials, which latter of course could now be avoided. With the advantage of present experience the electric haulage at Pouilly could now be carried out for about £4,800, exclusive of the accumulators which are of little use: so that the cost per mile would be about £4,800 ÷ 3·75 = £1,280. The saving in cost over the old steam-tugs is considerable. During a period of six months the cost of transport over the length of 3¾ miles was 0·68*d*. per ton by electric haulage, as against 0·99*d*. by the old method, or a saving of a little over 30 per cent. The time taken is also slightly less.

Running Rope.—A third plan of towing, by means of an endless running rope working along the canal bank, was tried in France for some considerable time by M. Maurice Lévy on the St. Maur Canal, and also on the St. Maurice Canal near Charenton, where nearly every difficulty likely to occur in practice seems to have been encountered. From experiments made both in France and in Prussia it has been found that this plan is practicable, and that it will probably prove satisfactory in respect of economy. To start such a plan means of course a heavy outlay upon machinery; and to make it successful the traffic must be frequent. The boats can be attached to the rope in a simple and ingenious way at any point along the route; and the difficulty of getting the attaching rope past the pulleys has been successfully overcome. One great difficulty which had to be surmounted was the rotation of the endless rope; this was overcome, and in 1891 the plan had been working perfectly for two years without an accident. The rope used was of steel wire, having a tensile strength of upwards of 50 tons. The supporting pulleys were placed as intervals of 230 to 262 feet apart. The two stationary engines driving the rope were each of 50 H.P. and about 15 miles apart, so that each worked a circuit corresponding with a length of about 7½ miles. The cost of traction by this plan on the St. Maurice Canal came to 0·039*d*. per ton-mile, including interest and redemption of machinery. This would point to the conclusion that, where the first outlay is warranted by the amount and nature of the traffic, the plan is not so expensive as might at first sight be expected.

On the Marne and Aisne Canal a method of traction has been in operation since the beginning of 1896, for a description of which the author is indebted to M. Bourguin, engineer-in-chief at Reims, under whose supervision the work has been executed. Since this plan has been got to work, the above experimental towage on the St. Maur and St. Maurice Canals has been discontinued. The present is the first really practical application of this plan, which is the invention of M. Maurice Lévy, to the traction of boats; and it is the only one of its kind at present at work. The total length of canal worked in this manner is only 1·37 mile, of which 1·18 mile is in tunnel, leaving in the open 0·10 mile at one end and 0·09 mile at the other. The tunnel of the Mont de Billy has so narrow a towing path that only horses accustomed to the work could get along it. As the supply of such horses was insufficient for the traffic, some other method of haulage had to be adopted; and towing by an endless running rope, which was then successfully working experimentally on the St. Maur and St. Maurice Canals, was decided upon. The work having been authorised in March, 1893, was begun in June, 1894, and finished 12 months later. Experiments were then made upon the new plan, and such improvements and alterations as seemed necessary were carried out. At the end of January, 1896, nearly the whole of the traffic was conveyed by the rope, in order that any minor difficulties which might be experienced in the daily working of the rope might be observed and removed. On May 1st, 1896, rope haulage was rendered compulsory, and has been in use successfully up to the present time. In order to get over the great difficulty of the tow line winding round the running rope, owing to the rotation of the latter, the boats are attached to the rope in the following manner. Where the attachment is to be made, a serving of twine, mixed with resin and pitch, is wound round the running rope for a length of about 7 inches, forming a protecting pad; a cast-steel collar in halves is then bolted tight upon the rope, bearing hard upon the serving of twine. Against the front face of the collar bears a cast-steel saddle, which has a short coupling rope passing round it and attached to it. One end of the coupling rope terminates in a pear-shaped bulb; and the other end, which is of the same length, has a piece of rope spliced to it, with a gap or eye left for a short distance between the two splices, just long enough to allow the pear-shaped bulb to be pushed through when the rope is slack; but the gap closes tight up directly tension is put on the rope, and prevents the bulb from pulling out of it. For disengaging, all that has to be done is to slacken the rope, and the bulb can at once be pulled out of the eye. The end of the rope containing the eye terminates in a loop, to which the tow line proper is fastened. The tow lines, which are provided by the management, last a considerable time, for apart from the pull upon them in towing there is nothing to wear them out. The coupling rope round the saddle, however, wears out quickly, in consequence of its passing over the pulleys carrying and guiding the running rope. At the present time the running rope is in good condition, and apparently will last four or five years. The pulleys are much worn by the passage of the collars and saddles, and will require renewing about every two years. The servings of twine wear out rapidly, and have to be replaced every fortnight. The saddles on the rope have also to be renewed every few months, because, being pressed tightly against the horizontal guide-pulleys, they get out of shape and constantly break. The traffic is worked in two convoys of eight boats each way per day. For a convoy of eight boats towed against the current, which is slight, 20 H.P. is required, the speed of the running rope being about three-quarters of a mile per hour. At the end remote from the works a telephone is provided, so that notice can be given to the engine house when a convoy is despatched, and also any other instructions can be sent.

(To be continued.)

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Compiled for "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL" by HERBERT HADDAN and Co., Registered Patent Agents, of 18, Buckingham Street, Strand, W.C., London.

Specifications Published.

28,648. Motors. Stephen Marius Balzer, 370, Gerard Avenue, New York, and William Henderson Humphrey, of Norfolk, Connecticut, both in the United States of America. December 15th, 1896.

In Fig. 1, 12 is a shaft which has a crank-pin, 14, shown carried by arms, 14ª, in well known manner, but, of course, the crank-shaft, 12, can be made in any desired manner, and may be carried in any suitable supports. The casing shown consists of a central shell, 15, which surrounds the crank, 14, and on the sides of this shell are bolted or otherwise fastened shells, 16, 17, which have tubular extensions or bearings, 16ª, 17ª, which receive and rotate upon the shaft, 12. Of course the central shell and one of the side shells could be made in a single structure, and the extensions or bearings, 16ª, 17ª, can be fitted with ball bearings to reduce friction on the shaft, 12. This casing or shell (its central portion, 15), carries suitably arranged cylinders, 18, which are secured thereto by screw threads or otherwise, and open into the interior of the casing (*see* Fig. 2), these cylinders being closed at their outer ends and aligned with the crank, 14. 19 is the piston within the cylinder, and 20 the piston-rod, which may be connected therewith by a ball-and-socket joint, 21, or otherwise, to allow independent movement between the piston and its rod (*see* Fig. 2). As there are a pleurality of piston-rods, 20, all working on the same crank-pin, 14, we provide each rod with a foot or extension, 22, the under surface of which is curved to correspond with the periphery of the pin, 14. The width of the feet, 22, of the rods, 20, is such as to leave a space between them so that said rods can have necessary oscillatory movements on the pin, 14. The feet, 22, of the piston-rods, 20, are held upon the pin, 14, so that the rods, 20, can effect a pulling action on the pin, 14, by rings, 23, which surround the feet, 22. The feet, 22, are held from movement along the pin, 14, by the crank-arms, 14ª (*see* Fig. 2). To adjust the rings, 23, in position around the pin, 14, and feet, 22, said rings are made in sections, and these rings are held together, and spaced apart, by studs, screws, or bolts, 24. To form a firm structure the sections of the rings, 23, overlap or are dovetailed together, and the bolts or screws pass through these joints. By preference, the studs, 24, are hollow, and screws or screw-bolts, 24ª, pass through them and

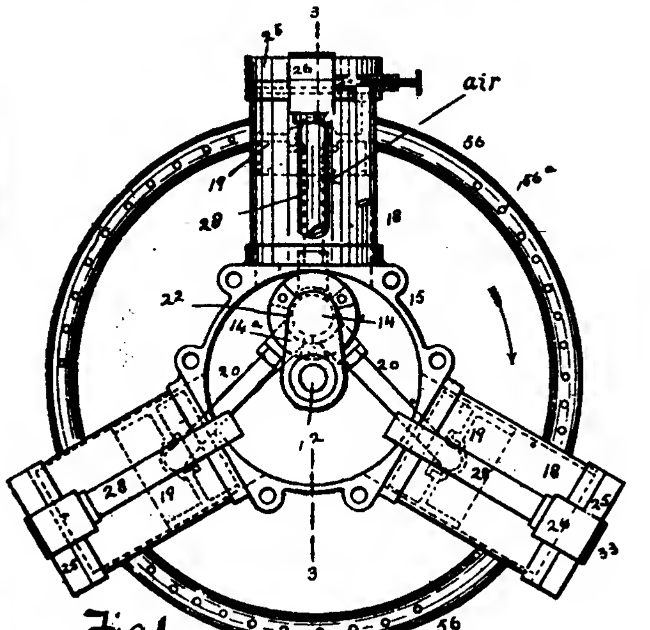

Fig 1.

28.648.

through the sections of the rings, 23, as shown in Fig. 2. In order to take up wear that may occur between the outer surfaces of the feet, 22, and the inner surfaces of the rings, 23, the outer surfaces of the feet, 22, are inclined outwardly, as in Fig. 2, so that as wear occurs the rings, 23, may be adjusted nearer the rods, 20.

The improved motor or engine is designed to be operated by hydrocarbon oil or vapour and air, but could be used with any other suitable propulsive medium. The outer end of each cylinder, 18, is provided with a plate or cover, 25, suitably connected therewith, and on one side of each plate is an enlargement, casting or housing, 26, having a chamber or channel, 27, into which projects an air pipe, 28. These pipes, at the opposite ends, pass into the chamber, 15ª, of the shell or casing, 15, 16, 17, and serve to draw air therefrom to supply the cylinders, 18, through the chambers or channels, 27. The portion, 12ª, of the shaft, 12, is hollow throughout, to admit air to the chamber, 15ª, and as air thus enters the casing, 15, 16, 17, it serves to cool the latter, and the contained mechanism. But it is evident that air could be admitted to chamber, 15ª, otherwise, say, for instance, by apertures in the side of the casing. But by the means shown the danger of dust, &c., entering the casing is reduced. It is also obvious that the pipes, 28, could take in air without receiving it from the chamber, 15ª.

The chamber or channel, 27, communicates with the cylinder, 18, by a channel, 29, in the plate or cover, 25, and a valve, 30, regulates communication between said chambers. The valve stem, 31, is shown passing through the plate or cover, 25, and provided with a spring, 32, suitably arranged, which normally holds the valve, 30, to its seat. The valve, 30, is operated by suction, as hereinafter explained, to admit air and oil or vapour to the cylinder, 18. 33 is a plug which closes the opening that admits the valve, 30, to its seat.

The valve, 30, regulates the admission of vapour or oil to the cylinder, 18, as well as air, and for this purpose a pipe, 34, leads to the valve-seat, and is fastened in the plate or cover, 25 (*see* Fig. 2), its delivery end being in line with the valve, 30, as shown in dotted lines in Fig. 2.

As the casing, 15, 16, 17, rotates, means are provided for supplying oil or vapour to the pipe, 34, through the portion, 12^b, of the shaft, 12, which for this purpose is hollow, its inner end being plugged, or in other words, the portion, 12^b, of the shaft has a bore to receive oil or vapour. For convenience of manufacture a hollow shaft or tube is used, the inner end of the portion, 12^b, being plugged. 12^c is a hole in the shaft leading to its bore, 12^d, and the bearing, 16^a, of the casing, 15, 16, 17, is provided with a chamber, 16^b, into which the hole. 12^c, opens. The chamber, 16^b, communicates with a channel, 34^a, in the bearing, 16^a, which channel connects with the pipe, 34. The pipe, 34, for this purpose passes into the casing, 16, as in Fig. 2. 35, 36 are suitable bushings in the bearing or extension, 16^a, through which the shaft, 12, passes, the bushing, 35, having an annular cavity, 35^a, and an aperture, 35^b, leading from the cavity, 35^a, to the chamber, 16^b. The bushings hold packing in place to keep oil properly in position, a cap, 37, on the bearing, 16^a, serving to keep said bushings and packing in place. Oil or vapour may be supplied to the bore, 12^d, of the shaft, 12, in any suitable manner.

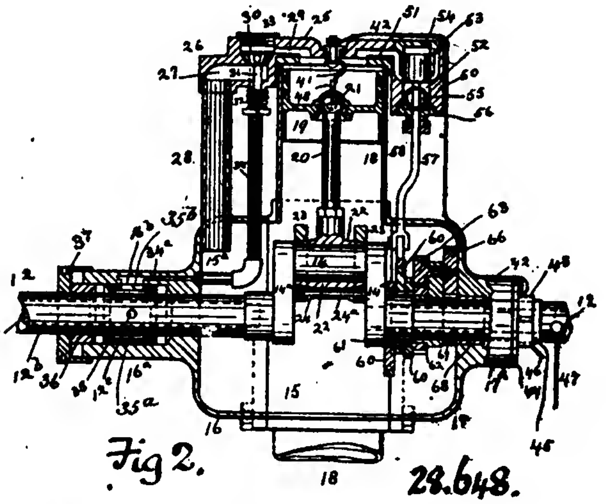

Fig 2.

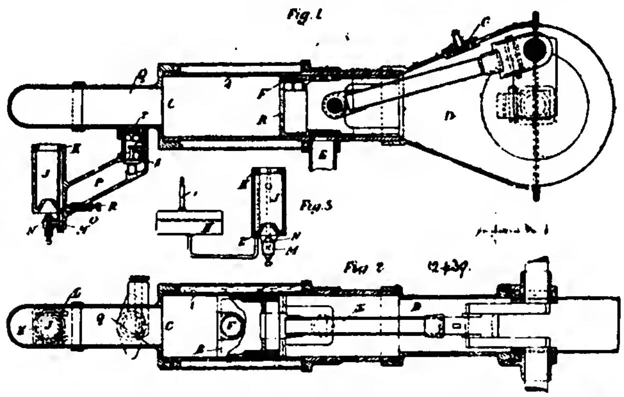
In the operation of this motor each cylinder makes two revolutions around shaft, 12, for each charge of propulsive material, and during the greater part of these two revolutions the valve, 53, keeps the port, 51, closed, and only opens at one instant to allow the escape of the exhausted charge. Or in other words, when the piston, 19, first moves towards the crank it draws in a charge of oil or vapour and air (this takes place during the first half revolution of the motor), the piston next recedes (during the other half revolution) and thus compresses the charge of oil or vapour and air. During the next half revolution of the motor the charge is exploded and expanded to give motion to the parts. While the motor is thus making one and one-half rotations the valve, 53, remains closed, but as soon as the piston starts to move back to the outer end of the cylinder, during the fourth half-revolution, the valve, 53, operates quickly to open the exhaust port and permit the expanded charge to escape. To cause these valves to thus operate at the proper time, the eccentrics, 60, are made independently rotative and cause them to rotate just one-half as fast as the cylinders, or, in other words, the cylinders make two rotations or revolutions around shaft, 12, to one rotation of the eccentrics, 60. As there are three cylinders, 18, we have shown three eccentrics, 60, one for each cylinder, and these eccentrics are connected together and rotated as follows:—61 is a sleeve mounted to rotate on the shaft, 12, which sleeve passes through the eccentrics and is keyed or otherwise secured to them. The eccentrics, 60, are located in proper position relatively to each other to cause the valves, 53, to operate at the proper time. The sleeve, 61, carries a pinion or spur teeth, 62, with which a pinion, 63, meshes. The spindle, 64, of the pinion, 63, is journaled in bearings on an arm, 65, that is secured to and projects from the shaft, 12, said spindle also carrying a pinion, 66, which meshes with spur teeth or a gear, 67, carried by the casing, 17. The teeth, 67, are shown carried by a tube, 68, which is socketted in and secured to the part, 17, of the casing or shell. By these means as the casing rotates, the eccentrics, 60, will be rotated together, through the gearing above mentioned, and the relation of the gearing is such that the eccentrics will be given but one complete revolution to two revolutions of the casing. The eccentrics, 60, have straps which are connected with the stems or rods, 57, to actuate the valves, 53. The relation of the parts is such that a cylinder, 18, can make three half turns before one eccentric, 60, will act to operate the valve, 53, because, as the eccentrics rotate but half as fast as the cylinders, they will be kept from operating the corresponding valve, 53, until such time as the exploded charge is to be exhausted.

12,489. Improvements in Oil-engines. Dugald Clerk, London. March 8th, 1897.

This invention relates to that type of engine in which an explosive mixture of air and oil-vapour or gas is formed, and ignited to give the required impulse or impulses, and where the necessary oil-vapour or gas is produced as required from liquid petroleum.

Fig. 1 is a vertical section through the engine, Fig. 2 is a horizontal section, and Fig. 3 is a detail view.

The engine has a single cylinder, A, and piston, B, as shown on Figs. 1 and 2, the back portion, C, of the cylinder acts as the motor end, while the front portion opens out into an enclosed crank-chamber, D. The motor impulses take place every revolution behind



the piston, B, while the air in front is compressed into the crank-chamber, D, to a few pounds above atmosphere. The piston, B, over-runs an exhaust port, E, at or about the end of its stroke, when the pressure at the motor end falls to atmosphere, and at this time the compressed air in the crank-chamber blows open a non-return lift valve, F (preferably placed in the piston, as shown), so that the air from the crank-chamber, D, flows into the motor end, C, of the cylinder, and scavenges out the burnt gases through the exhaust port, E.

An air suction valve, G, is arranged in the crank-chamber, D, so that on every back stroke of the piston air is drawn in.

To produce the oil-vapour as required for supplying the engine there is a small reservoir of oil, H, as shown in detail, Fig. 3 (the ordinary lamp oils of high flashing points in use in this country being preferably employed) with its surface kept under a constant air pressure of from 10 to 30 lbs. by means of an ordinary air pump such as I.

There is a vapour lamp, J, of a somewhat similar construction to that known as the "Wells," as illustrated. It consists of a metal coil, K, having the end, L, communicating with the oil reservoir, H, while the other end, M, leads to the nozzle burner, N, fixed centrally underneath the coil.

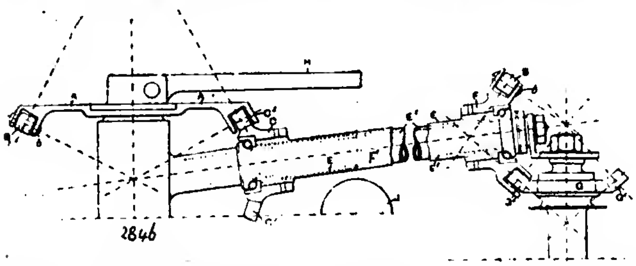
In the lamp, J, shown on the drawings, the coil, K, for convenience of making and cleaning is formed by drilling straight holes leading one into the other. The lamp, J, is put into action by a preliminary heating before oil is admitted from the reservoir, H. When the oil is admitted up past L, the hot coil at once vaporises it, and a jet of vapour at high velocity issues from the burner, N. This jet is lit, and passing through the coil, K, keeps up the production of vapour as long as the lamp is kept burning. On the side of the nozzle burner, N, is fixed a small bye-pass pipe, O, which leads to a small chamber, P. This chamber is of sufficient size to hold one charge of vapour (for one impulse of the engine) at a pressure in excess of atmospheric pressure, and has on its end two small valves, S and T, opening into the combustion and ignition tube space, Q, of the engine herein referred to and controlled by the governor. The bye-pass pipe, O, allows the chamber to fill up with oil-vapour at a similar pressure to that in the nozzle burner, and it is evident that as this supply is drawn off to feed the engine the bye-pass will at once fill it up again. The size of opening from either end of the bye-pass may be arranged with an adjusting device, such as R.

On the end of the motor cylinder, A, is an extension, O (preferably tubular) of the combustion or compression space, and the Bunsen lamp flame impinges on this tube so that it forms a combined combustion chamber and ignition tube. The oil-vapour from the chamber, P, is admitted at the termination of exhaust and scavenging into this tube, Q, but as sufficient air is not present, no ignition takes place; however, on the back stroke of the piston air is forced into the tube, Q, and mixing with the vapour at the hot end, explosion takes place, and thus a motor impulse is provided. By so arranging the length of the tube and the extent and position of heating, the explosions may be accurately timed.

2,846. Improvements in Bevel Gearing. William Edwin Heys, Manchester. February 2nd, 1897.

This invention relates to gearing for the transmission of rotary motion.

As represented by the drawing, the crank axis carries wheel, A, in substitution for the ordinary teeth of which are arranged small friction rollers, B, free to turn upon the fixed axes, *b*. The axes of these rollers are not radial, parallel with the plane of the wheel, but in the surface of the cone to which the wheels are constructed as indicated. The rollers themselves are cylindrical, with one or with both ends rounded so as to prevent friction between them and the walls of the recess or cavity within which they are mounted. The



wheel, A, gears with a pinion, C, which has the ordinary or any suitable special form of smooth fixed teeth, C[1]. This pinion is screwed or otherwise fixed on the end of a ferrule or sleeve, E, which is mounted and capable of rotation, with or without ball bearings, upon the rod or tube, E[1], which may form part of the framing of the machine. The opposite end of this ferrule or sleeve has similarly fixed upon it the wheel, F, furnished as A, with friction rollers in substitution for teeth, near to the hub of the driving or back wheel, upon which is fixed the pinion, G, having fixed teeth, G[1], similar to those of the pinion, C, gearing with the wheel, G.

12,601. Motor Carriages. John Johnston, 2, Bush Street East, Pembroke Dock, Pembroke. June 9th, 1896.

This invention consists of improvements relating to motor carriages, the object being to provide more efficient and reliable means for steering than exists with the vehicles at present in use.

In the application of the invention to a motor carriage having two back wheels, such wheels are mounted upon separate axles coupled together by compensating gear, arranged in the ordinary manner to permit one wheel to over-run the other, and thus enable the vehicle to be turned round a sharp corner. Upon each of the back axles is mounted a brake wheel and a friction block adjacent to each wheel upon the short arm of a brake lever. At the extremity of the long arm of each brake lever is formed a hole or aperture to admit a steering rod which is connected with a hand or foot operating lever in any ordinary manner. Upon the steering rod are attached two collars adjacent to the brake levers, a spring between each of the levers and the adjacent collar or projection from the steering rod. Steering is effected by the application of the friction block to one or the other of the brake wheels; the adjacent wheel of the vehicle being thus retarded, the opposite one over-runs it, and causes the vehicle to swing round.

When the carriage is in motion the front wheels can be caused to swing or slew round in either direction by the operation of the steering gear, by pivoting them forward, of the centre of the axle, but the slewing is effected against the resistance of springs, such resistance always tending to return the wheels to their central or normal position. The motion of the carriage is thus maintained in a straight line direction until forcibly turned aside by the operation of the steering gear, and such steering can be readily effected without producing a jerky or unsteady motion of the vehicle.

In the construction of steering gear for a motor carriage having but one front wheel, the spring or springs is or are arranged upon the central steering head in such a manner that when the steering head is turning a torsional force is imposed upon the spring, thus setting up a resistance tending to return the head to its central position.

12,894. Framings of Autocars, &c. Wolseley Sheep Shearing Machine Company (Limited), Sydney Works, Alma Street, Birmingham, and Herbert Austin, of the same address. June 6th, 1896.

According to this invention the two side frames of the body of an autocar or self-propelled road vehicle are formed, as seen in side elevation, each of upper and lower longitudinal members joined together at their ends by pillars which, preferably, incline somewhat towards one another upwards, and of diagonal members or braces which join the upper corners with the middle of the lower longitudinal member; and the socket piece or mounting which forms the joint between such diagonal members and the lower longitudinal member is conveniently formed at its upper end as an eye, or otherwise, to carry the axle. A rail or guard may extend above the top of the upper longitudinal member, being conveniently formed with a longitudinal portion and downward portions which are fixed at their lower ends to the corners of the frame and are joined by curves at their upper ends into the ends of the longitudinal portion.

The portions of the framing which extend forwards of the frames above described vary according to the character of the vehicle and method of steering the same.

1,972. Carbonic Acid Engines or Motors. Adolphe Delsemme, No. 32, Avenue Rogier, Liege, Belgium. January 25th, 1897.

This invention has for its object a carbonic acid engine or motor, and it consists in connecting the motor cylinder or cylinders to a reservoir formed of metal, suitable for containing the carbonic acid under pressure in a liquid state, and into which enters an electric conductor, the ends of which are connected to the two poles of a dynamo, or other source of electricity, in such a manner that when an electric current passes through the conducting wire, there results a heating of the carbonic acid which in the form of gas at high tension enters the motor cylinder or cylinders for acting upon the piston or pistons.

A dynamo is provided which, when the car is in motion, is driven by one of the car wheels, from which motion is communicated to the dynamo through bevel gearing, or through any other suitable medium.

A small battery of accumulators is connected to the dynamo, and which stores sufficient electricity to furnish the current necessary for starting the vehicle.

A receptacle contains the liquid carbonic acid. The said receptacle is surrounded with insulating material, and into it enters the conducting wire, which conveys from the dynamo the current which heats the carbonic acid. This receptacle communicates with the motor cylinders by a pipe furnished with a suitable valve conveniently connected to levers, by means of which the driver of the car can regulate the supply of carbonic acid gas to the cylinders.

Pipes form communications between the receptacle and heat and pressure gauges situated near the driver for the purpose of indicating to him the degree of heating and pressure of the carbonic acid. Make and break devices arranged in the circuit of the conducting wires enable the driver to control the passage of the current to the receiver.

IN AID OF AUTOMOBILISM.

IT is, as a rule, an unwise thing to prefer a request unless a favourable reply can be assured. Most people interested in the development of automobilism will, we think, agree with us in the opinion that in asking the Liverpool City Council for a grant in aid of the forthcoming trials next May, the Self-Propelled Traffic Association (Liverpool Centre) took a rather ill-advised action, and exposed itself to a needless snub. From the Liverpool papers we learn that at a recent meeting of the Corporation a letter was read from Mr. E. Shrapnell Smith, hon. organising secretary of the Self-Propelled Traffic Association, asking the City Council to grant £200 towards the expense of the trials of motor vehicles for heavy traffic to be held in Liverpool in May next. The Finance Committee decided to decline the application, a grant by the Council being *ultra vires*. That this result should have been reached was only to be expected by anyone knowing the Liverpool Corporation, which, like most similar bodies, is composed of well-to-do, well-intentioned, but not very liberal-minded persons. Can any good thing come out of a body that objects to the Nude in Art, and which entertains a truly moral and provincial view of the awful depravity associated with what some of its members unctuously term the Continental Sunday? From the report quoted we learn that the request was refused because it was *ultra vires*. *Ultra vires* is, as Shallow would say—"Yea, indeed, a good phrase," but, we would observe, quite out of place in this connection. Why should a request for public funds in aid of a public object be *ultra vires?* It is, of course, too much to expect that a real British municipality, such as Liverpool, can so far rise superior to its narrow-minded provincialism as to encourage automobilism. This would be indirectly encouraging travelling on Sundays! Liverpool rejoices in many (and much needed) means for the "elevation of the masses." Thus it owns a very fine and large organ, and pays an organist an inordinately large salary to perform on it. On each Sunday a selection of what is called "Sacred Music" is ground out on the aforesaid organ, and the well-dressed people of the middle and lower middle classes have their "religious feelings" comfortably excited by doses of the "Lost Chord," "Nazareth," and things of that kind, which, it is needless to remark, would not be tolerated in a first-class London concert hall. This means of spending a "pleasant Sunday afternoon" costs about £1,500 per year to the ratepayers. We say nothing more than this, that *if* any practical benefit result the money is well spent. This expenditure of public money on what is a scheme of exceedingly doubtful utility is—such is municipal logic—*not ultra vires*. A grant of a few hundred pounds, which would enable a problem in applied science to be solved, and which solution would be of incalculable benefit to Liverpool, in that it would lessen the burden of that terrible incubus known as "Port Charges and Town Dues," and which gives Liverpool such a bad name with shippers all over the world is, however—such, again, is municipal logic—distinctly *ultra vires*.

It is, we think, to be regretted that the S.P.T.A. ever preferred this request. The reply was so obvious. It is difficult to obtain exact, or even approximate, figures stating what the employment of horses in cabs, omnibuses, trams, carts, &c., costs a municipality in street cleaning—in getting rid of the excremental matter, in wear of roadway, and lastly, but by no means of small import, the mental irritation caused to citizens through the clatter of innumerable horses' feet on granite pavements. The sum must, however—and this is certain—be a very large one: and if a public body is not justified in spending money upon even experimental means for abating a growing nuisance, upon what object, in the name of common sense, is it justified in spending money? To refuse the request of the S.P.T.A. because it was *ultra vires* shows that the Finance Committee uses words like Mrs. Malaprop. But to refuse the request at all was an exceedingly illiberal and undignified proceeding. Contrast the behaviour of the Liverpool Corporation with that of Continental municipalities. In the encouragement of automobilism—which we cannot repeat too often means cheap internal transport—the French municipalities are surprisingly liberal. Paris, Marseilles, Bordeaux, Dieppe, Rouen, have found it to be distinctly *not ultra vires* to vote large sums in furthering the cause of automobilism. We now see the authorities of Amsterdam making preparations for the Automobile Congress that is to take place next year, while all the large towns lying *en route* between Paris and St. Petersburg will cheerfully vote money for the same purpose. Yet Liverpool will not grant a small sum of £200 to further a project from which she has everything to expect. Did a member of the Royal Family express a wish to visit Liverpool the same committee would spend thousands of the ratepayers' money. This would *not* be *ultra vires*, but a request for a small sum to aid in the solution of a practical problem in automobilism is churlishly refused because it is *ultra vires*. We can only say, in the words of the immortal "Chicken," "Why it's mean."

THE SERPOLLET BURNER.

M. SERPOLLET has recently patented a new form of liquid fuel burner which we illustrate herewith, and which possesses some features of interest. In this burner petroleum vapour or gas is injected under pressure in a Bunsen burner, and is there burnt,

FIG. 2.

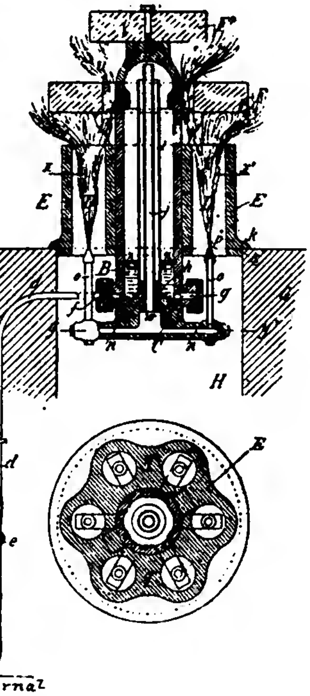

FIG. 1.

mixed with the heated air which is sucked in, and heated by contact with the hot metal of the frame. Referring to the drawings, *A* is the reservoir of petroleum under pressure, the upper part of the chamber being in communication with a pressure gauge, *b*; the arrangement being almost exactly similar to that adopted by Wells and other makers in their petroleum lamps. A pipe, *d* (*see* Fig. 1), conveys the petroleum to the burner, *B*, the quantity of oil passing being regulated by the gauge and valve, *E*. The oil passing into the central chamber is heated, and the vapour generated passes down the central tube through *W* (Figs. 1 and 2), to the burners, *o*, *o*, whence it issues as gas, and the flames, *D*, playing upon the refractory walls, *E*, and the heating surfaces, *F*, *F*[1], causes the latter to become highly heated, and not only is the radiation very intense, but these thick refractory walls, &c., act as reservoirs of heat so that in

FIG. 3.

the event of the supply being temporarily shut off the furnace will remain hot for a long time, and on again turning on the oil it is immediately gasified as described. The air is admitted below the burner through *H*. Fig. 3 shows a different arrangement, the oil as before passes into a central chamber, *B*, and is vaporised and issues as gas at *o*, the jet playing downwards through the passages, *D*, and heating all the central portion; air is admitted through the pipe, *H*. It will be gathered by those familiar with petroleum burners that M. Serpollet has not introduced any specially novel features, and we should not like to say that his burner presents any material point of practical superiority over those which have been previously described by us. We would remind our readers that the most suitable forms of petroleum burners are fully described and illustrated in our AUTOMOTOR POCKET-BOOK for 1898.

A HALTING VESTRY.

WE had thought that Shoreditch, by the establishment of its dust destructor and excellent electric-lighting arrangement, had earned for itself the reputation of being an up-to-date and progressive community. In the matters mentioned it certainly leads the way. We are sorry to have to modify our opinion somewhat, but the Vestry has not exhibited the same foresight and intelligence in dealing with automobilism as it did in dealing with the disposal of the refuse question. From a recent issue of the *Hackney Express* we learn that some enlightened member of the Vestry had proposed, and very properly too, to employ motor disinfecting vans. The Public Health Committee, as instructed by the Vestry, had considered this question, and had received a report from the medical officer of health as to the cost of electric motor-cars adapted for the purpose of conveying goods to and from the Vestry's disinfecting station. The amount to be laid out would be at least £400, but the cost would be somewhat less if the bodies of the old vans could be utilised. Dr. Bryett pointed out that motor-cars are at present a novelty. Whenever they stop in the streets, small crowds, mostly of children, collect round them, and in the case of a car used for conveying infected articles, there would be a very considerable amount of risk of infection. The committee were therefore of opinion that it is not advisable to try the experiment of using motors for this purpose, and they recommended accordingly.

The committee further reported that the average sum annually paid for horse hire during the past four years was £83 18*s*. 6*d*., and they estimated the cost of maintaining a horse belonging to the vestry at £53 10*s*. As the estimated saving to the vestry would be upwards of £30 per annum, the committee recommended that an extra horse be purchased for the use of the Public Health Department at a cost not exceeding 30 guineas, and a set of harness at an estimated cost of £8.

We would beg the Vestry not to be misled by the report of this medical officer. This person cannot possibly be an authority on motor-vans. The price he mentions is far too high, while the reasons he adduces against the use of a motor-van are shallow and jejune. Whenever a fever patient is being conveyed from a house, in the easily recognised hospital vehicle, there is always a crowd of small boys. So there is when a fire-engine makes its appearance. The committee is, we think, justified in rejecting this report as being inaccurate and, no doubt unintentionally, misleading. It seems also obvious from the figures relating to the cost of horses that neither the committee nor the person responsible for the estimate understands the "law of economy" which governs these things, and which we expounded in our October number. We would recommend a perusal of this with advantage to all vestrymen and their officials.

THE COACHMAKERS' COMPANY AND A CHANCE FOR THE MOTOR-CAR.

OUR always interesting, frequently well informed, but, like its prototype, the *Daily Chronicle*, too hysterical contemporary, *London*, as befits its position as an organ of municipalisation, keeps, as does its exemplar, a watchful and somewhat suspicious eye upon the old City Companies. Whether the latter appreciate the attention is, of course, quite another matter. In a recent issue our contemporary, under the heading "A Chance for the Motor-Car," in the course of a not altogether undeserved eulogy of the Coachmakers' Company, makes the following (to us) extraordinary statement :—

"The Coachmakers' Company have given the fullest encouragement to the motor-car. One would not have been surprised to find a Company, with members representing some of the largest firms in the country, looking askance upon the newcomer lest their own business be interfered with. But, no. With that keen business foresight which recognises that progress lies along the line of new inventions, they have welcomed the motor-car, and gone out of their way to give it encouragement. Last year, for instance, they offered a first prize of £20, and another of £10, for the best designs of a motor-carriage. So poor were the exhibits that the prizes could not reasonably be awarded. The limitations imposed may have had something to do with the shortcomings of the designs sent in. Anyhow, this year a wider field has been opened. Instead of limiting the competitions to coachmakers only, they are free to 'British subjects generally resident in the United Kingdom of Great Britain or Ireland.' This is certainly wide enough, and ought to bring in some of the many outsiders who feel keenly that the motor-car, or cab, or carriage, is yet far from being a sightly or convenient mode of transit."

The Coachmakers' Company has certainly displayed a broad-minded appreciation of the automotor vehicle, which we gladly acknowledge; but careful and well-thought-out designs of new machines are hardly to be obtained by such inducements as prizes of £10 or £20. A well-known coachbuilder so clearly recognised this that not long ago he offered, through the AUTOMOTOR, £100 for a suitable design. Even allowing, for the moment, that out of the callow minds of apprentices and improvers a fairly good design can be evolved, is it yet to be expected that such young men can produce the design of a wholly new type of vehicle, propelled in a wholly different way, and involving mechanical knowledge, or rather a knowledge of engineering principles and mechanics, that a locomotive engineer has to have, but which no coachbuilder, so far as we are aware, either has or pretends to have? The competition, in so far as it related to motor-vehicles, was distinctly premature. What, too, we may ask, were the qualifications (we speak as an engineer) of those who would decide on these designs? The question of merit in the design of a motor-vehicle can only be answered by those who have a pretty extensive knowledge of automobilism. An ordinary cart or carriage is not a self-moving vehicle, even when running down hill; and while we should unhesitatingly defer to the opinion of a coachbuilder on coaches, we should not accept it as necessarily possessing any value as regards automobile vehicles. We are afraid, however, that *London* lives in the same benighted ignorance as do so many of the London papers on things relating to automobilism, whether this relates to aeronautics, submarine boats, torpedoes, or automobile vehicles. We have occasion elsewhere to draw attention to this lamentable display of want of common knowledge on the part of the lay Press. Referring to the latter part of the quotation from our contemporary, it will be seen that *London* imagines that the Coachmakers' Company is again offering prizes for designs for motor-vehicles. *London* rejoices that this will bring comfort to those who "feel keenly," &c. We are sorry to disappoint any respectable person who "feels keenly," as does our contemporary, that the motor-carriage is not yet a convenient mode of transit, but truth compels us to say that our contemporary is misinformed. The Coachmakers' Company officially inform us that they "are *not* offering any prizes for motor-car designs in the coming year (1898)," as we pointed out some months back; and we think wisely, too, for reasons we have stated. It will thus be seen that the whole bottom is knocked out of our contemporary's article entitled "A Chance for the Motor-Car."

MUNICIPALITIES AND AUTOMOBILISM.

WE are glad to observe an increasing interest taken by municipal bodies in automobilism. It is at length very generally recognised that by the adoption of automobile vehicles a great saving in the rates can be effected. Indeed, so heavy are those in many districts that any increase is out of the question. One of the heaviest charges is that incurred in keeping the roads and streets clean, in carting away the sweepings, &c. So long as horses are employed to the unreasoning extent that they are, the streets in large towns can only be maintained in a healthy state by employing a large army of sweepers, whose business is to collect the fæcal matter as fast as it is deposited; then comes in the question of the disposal of this. Farmers sometimes will take it, at other times they will not have it as a gift; it then has to be carted or barged away. Those who have to deal with these municipal matters know that this question of street cleansing is a most costly and unsatisfactory one. If horse traffic could be prohibited in, say, the precincts of the City of London, the cost of keeping the streets clean would be less than one-fifth of what it is at present. Another vexatious item of cost is the large number of horses that a municipal body has either to maintain itself or else through a contractor.

Automobilism offers the very best remedy for these things, and the more advanced and enlightened municipal bodies are recognising this. Thus Chiswick set an example which Leicester has followed, and now, as will be seen from our advertising columns, Wolverhampton follows suit, and is anxious to obtain a motor-van. We congratulate the Corporation on their foresight, and we have but little doubt that they will find this experiment a complete success. From the outline specification, which, by the way, is well drawn up by the borough engineer, Mr. J. W. Bradley, C.E., it is evident that the Corporation mean to have a first-class vehicle. Here is an excellent opportunity for engineers to show what they can do. This is the germ of what will be a gigantic industry. If automotor vehicles are employed for no other purposes but for that of scavenging there will be work sufficient for a score of firms. Before leaving the subject we would ask how it is that the London County Council is so deficient in municipal enterprise. It does not possess a single automobile vehicle. It is as backward as the City Corporation.

ROOTS AND VENABLES' OIL-MOTORS AND MECHANISM FOR VEHICLES.

THIS firm have been consistently working for many years past at the improvement of the oil-engine, and have succeeded in greatly increasing the mechanical efficiency and simplifying the mechanical details of the oil-motor using "heavy" oil and working on the Beau de Rochas cycle. The following is a description of their latest model, intended for road vehicles, and embodies their most recent improvements:—

The crank-pit is enclosed and is air-tight, and is made in two portions bolted together, each carrying a bearing. The movement of the piston producing suction and compression within the crank-pit is utilised to deliver air (suction and delivery valves being fitted for this purpose) to a chamber bolted or screwed to the side of the crank-pit. This chamber forms the air-pressure reservoir, so that the pressure in the delivery pipe shall be equable and steady. The delivery pipe conveys the air to the end of the oil-feeder, and the groove cut in the oil-feed spindle to supply the burner delivers its oil to the blast of air. The oil is conveyed, together with the air, in a pipe which, after passing once round the vaporiser, reaches the ignition tube. The counter-shaft operating the exhaust valve is driven by a chain and chain-wheels at half the speed of the crank-shaft. This half speed shaft may convey the power of the motor; it has fitted between its bearings a governor weight in one casting connected by a link to a sleeve within the groove on which works one arm of a lever, the other end of which lever moves a small slide which, as the speed becomes excessive slides in front of a block upon the exhaust-valve spindle, the pin through which block of hardened steel operates the oil-feed spindle lever. The end of the exhaust-valve spindle telescopes within the cylindrical slide that carries the roller running on the face of the cam which is keyed upon the valve counter-shaft. The vaporiser of the patentee's usual construction is surrounded by a cover, through a slot in the floor of which the starting burner is placed for starting. The air for the combustion in the cylinder passes by a pipe through the floor plate of the cover, and has a filter of some textile fabric or wire gauze fitted at its end. The additional air pipe is fed from the same filter. In a twin-cylinder engine one set of chain and chain-wheels are used, and one governor and sleeve which operates one slide for holding open the exhaust valves, and thus stopping the feed of oil, the two cranks being placed in the one crank-pit with a bearing between them.

Referring to the drawings, Fig. 1 is a sectional elevation of the single-cylinder motor for vehicles, &c.; Fig. 2 is a part sectional plan of the same; Fig. 3 is a part sectional plan of a similar but twin-cylinder motor; Fig. 4 shows a fly-wheel of this motor with a water-cooling coil attached.

In a motor for driving the front wheel of cycles and vehicles, the motor bearing is preferably formed by and passes through the axle of the wheel. A steel tube is screwed or otherwise secured into the bearing boss on the casting forming the crank-pit of the motor; within this, a close-bearing fit, the crank-shaft turns, on the outside of this tube, on ball bearings, the vehicle or cycle driving-wheel turns. The motor is on one side of the fly-wheel preferably placed vertically and the fly-wheel is on the other side. On the fly-wheel side of the shaft a chain-wheel is fixed, driving by chain a chain-wheel of double the size fixed on the shaft, at the top of the motor. The motor may form one arm or prong of the fork, the other arm is formed of a single-steel or double-steel tube. The top counter shaft running at half-speed drives the valve gear. The valves may be of the ordinary mushroom type, working in the usual manner. A rotating valve may feed the petroleum oil or spirit. In the small cycle-motor a fixed quantity is measured by the pocket in the plug and is swept through into the cylinder by the suction. When the speed is excessive the supply is cut off by ceasing to turn the plug valve by means of the governor. On a second short spindle, parallel with the former, is fitted a chain-wheel which drives the pneumatic or vehicle wheel through a chain-wheel fixed to the hub. Upon both spindles are fixed two toothed wheels. The one or the other pair of wheels is brought into gear to change the speed as desired by shifting the spindle or a sleeve upon it sideways—the chain-wheel to permit of it being fixed on a feather. Springs may be fitted to the chain-wheel to take the first shock of gearing.

Referring to Figs. 1, 2, and 3, A is the cylinder, B the piston, C the crank-shaft, D the crank-pit chamber, D_1 the air cushion chamber, E the cylinder cover, F the cylinder jacket, G the admission valve, H the exhaust valve. H^1 is the slide operating the valve, H^2 the exhaust valve cam, I the cam shaft. H^3 is the oil-feed lever having its fulcrum at H^4. The lever, H^3, is operated by the pin fixed on the block fitted on the spindle of the exhaust valve, H. J is the oil-feed spindle of the patentee's usual construction with two grooves—the one for supplying the cylinder with oil, the other groove feeds the automatic burner, as described in the Specification No. 14,756 of 1896. The shaft, I, is driven at half speed by means of the two chain-wheels, I^1 I^2, it operates the valve, H, and the oil-feeder, J, by means of the cam, H^2. K is the governor weight, pivoted by means of a pin through the shaft, so that a degree of oscillation upon its pin is permitted. K^1 is the link connecting K to the sleeve K^2. The sleeve, K^2, operates the forked lever, K^3. The lever, K^3, slides the sliding piece, K^4, in the guide, K^5, and places it behind the block, K^6, on the exhaust valve spindle, which prevents the closing of the exhaust valve, H. As the lever, H^3, is operated by means of a pin, K^7, fixed on the block, K^6 (the end of the exhaust valve spindle telescopes within the roller slide, H^1), the prevention of the full stroke of the valve, H, prevents also the full stroke of the oil-feed spindle, J, so that the groove, J^1, which normally supplies oil to form the explosive mixture in the cylinder, no longer supplies oil, the stroke of the spindle being too short for the groove, J^1, to enter the oil, but nevertheless a small quantity of oil is fed to the vaporiser sufficient to keep the vaporiser channels moist with oil awaiting the first working stroke following the cutting-out of the governor. A small quantity clings to the spindle in its movement, which gives the slight excess above the usual feed per stroke which is so necessary for that working stroke following the cut-out. The groove, J^2, supplies oil for the automatic burner, Z^1, within the vaporiser, Z, by means of the pipe, J^3, the air-blast of which is supplied by

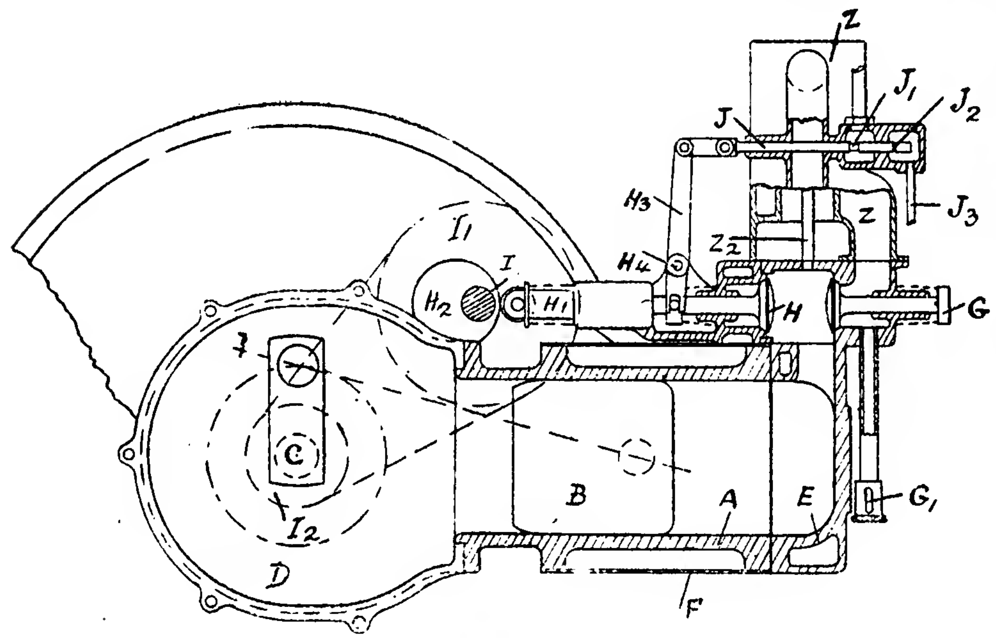

FIG. 1.

the pipe, J^4, in the manner set forth in the Specification No 14,756 of 1896.

In the twin-cylinder engine shown in plan, Fig. 3, a similar arrangement of parts is shown as in the single-cylinder engine in Fig. 2, one chain and pair of chain-wheels are used to drive the counter-shaft to which are keyed the two cams, H^2 H^2. The whole valve-gear comes between the two bearings of the counter-shaft, I, as in the single-cylinder engine and the two exhaust valves, H, are fitted to and operate in one casting. Two burner nozzles, Z^1 Z^1, are fitted to play upon the ignition tubes, Z^2 Z^2, within the vaporiser, Z. This vaporiser (having two separate oil-feeders) is divided into two distinct channels, so that the air for the cylinder, A, is always drawn through its own half of the vaporiser, and the same with the other cylinder. From the entrance of the air at Z^3 (not shown) to its passage through the valve, G, as section, Fig. 1, it is retained in a separate channel throughout to the air for the other cylinder. The two crank-pit chambers have one bearing between them fitted to the dividing wall, each chamber is air-tight from the other and delivers air from the

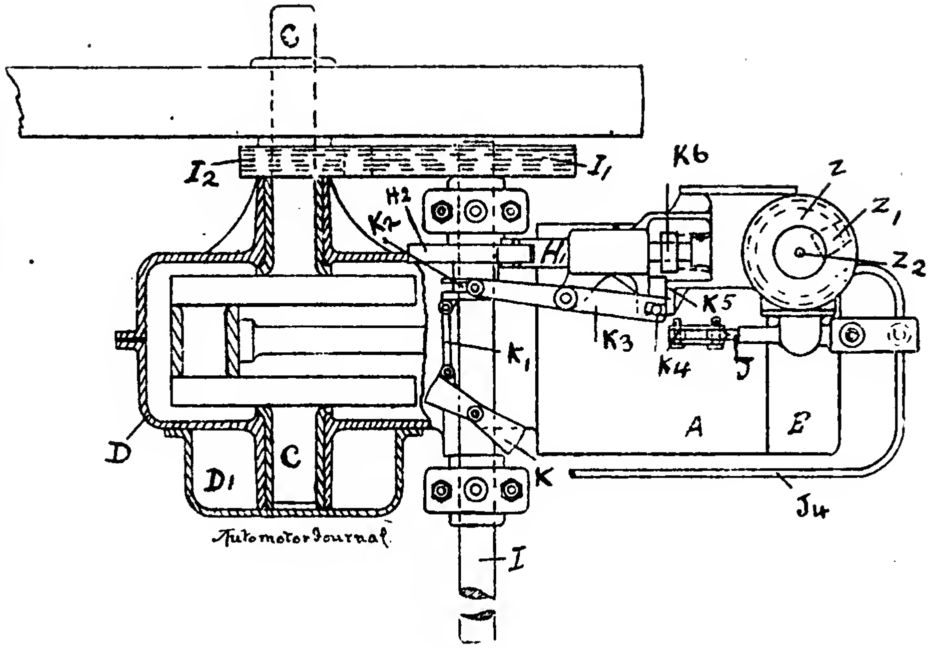

FIG. 2.

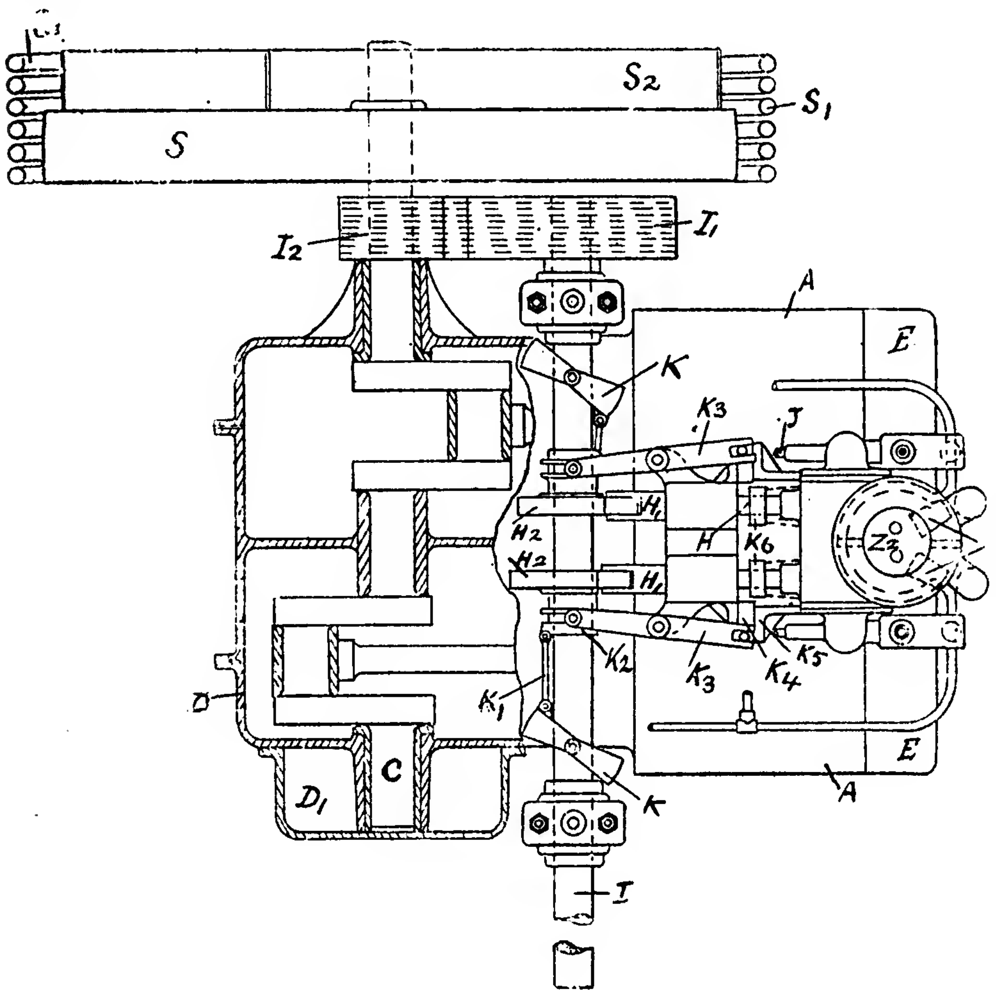

FIG 3.

chamber, D_1, for the air-blast supply of the automatic burners playing upon the two tubes, Z^2 Z^2, within the vaporiser.

Wire-gauze filters may be applied to the ends of the two air inlets, Fig. 1, the air inlet for the vaporiser not shown, and G^1 the additional air inlet.

Referring to Fig. 4, the motor is placed on one side of the driving-wheel, which is preferably the front and steering-wheel, and the fly-wheel and driving-chain on the other. A is the cylinder, B the piston, C the crank-shaft, D the closed crank-pit casing or chamber, E the cylinder cover, F^1 are ribs cast in the usual manner on the cylinder to cool it by radiation, but it must be understood the ribs are shown as an alternative, as the water-jacket is more reliable.

The tubes, XX, form one side of the usual front wheel fork of a bicycle or tricycle, while the cylinder and crank-pit casing form the other side of the fork; the head of the fork and the handles are not shown. X^1 is the front wheel of the motocycle, bicycle, or tricycle, although the motor may be equally well applied to the back wheel of a bicycle or the axle of a tricycle.

The wheel I^1 having twice the teeth of the wheel I^2, the countershaft, I, which operates the valves and transmits the power, rotates at half the speed of the crank-shaft. The crank-pit, D, is in one casting, having the closing plate, D_2, to form

K 4

an air-tight cover. The crank-pin then works in oil, as it does in the horizontal motor shown in Figs. 1, 2, and 3. The crank-shaft, C, has its bearing in the steel tube, C^1, which extends through the wheel from the crank to the chain-wheel, I_1. The bearing of the casting, D, screws over it at one end, and at the other is held by the nuts at the foot of the fork. The cones of the ball-bearings of the hub of the wheel, X_1, fit over the steel tube, C^1.

In Fig. 3 is shown the method of cooling the jacket water. S is the fly-wheel of the motor, the coil of piping, S^1, surrounds it, the water is pumped in at the one end of the coil and forced right

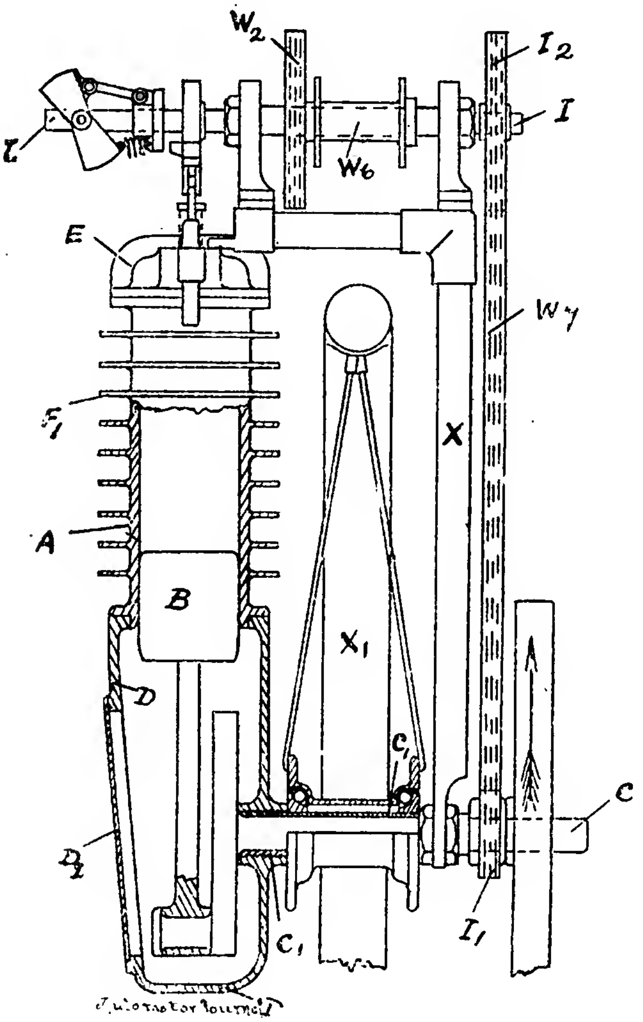

Fig. 4.

round and out the other end into the water tank, if one be used, or if the coil be of sufficient length no water tank will be necessary, and the water can return to the jacket cooled. Sixteen claims are made. The specification is numbered 23,604 of 1896, and is dated August 23rd, 1897.

Another Progressive Municipality.—At Southampton recently Mr. Alderman Lemon moved: "That the Team Labour Committee be requested to invite designs and tenders for motor-vehicles for the collection of house refuse." He asserted that electric motors were cheaper than horse traction. He intended to insert an advertisement for tenders, so as to obtain information. The motion was duly seconded, and after the, of course, necessary amount of opposition from those sitting on the fence, was carried. We congratulate the good people of Southampton on the progressive spirit thus manifested, and trust they will obtain their heart's desire in the shape of a motor dust-cart.

THE ELECTRICAL CAB IN LEEDS.

One of the new electrical cabs, of the kind now running in London, was tried in Leeds a few days since. Some time ago the London Electrical Cab Company (Limited) applied to the Hackney Carriage Committee of the Corporation for permission to run 50 of the new vehicles in the city. Having regard to the interests of the public, as well as the local cab proprietors, the committee decided that before licensing any motor-cabs one should be brought to the city on trial. This vehicle arrived on Monday night, January 3rd, and was tried on the following day. It was a novelty to most people, and whenever it pulled up a crowd soon gathered around it. Those who had an opportunity of riding in it expressed their entire satisfaction, more especially at the manner in which it can be manœuvred amongst other vehicular traffic. It has been built for the comparatively smooth thoroughfares of London, and jolted a little over the rougher pavement of Leeds. The promoters of the new conveyance state, however, that should the Hackney Carriage Committee decide to license any of the electrical cabs, the springs shall be arranged so that in passing over the worst paved streets there shall be little or no vibration. The carriage in question is built on the lines of the brougham, and has been fully described in our columns. Provisional arrangements have already been made for supplying electricity to such cabs as may be licensed to ply in Leeds. The Yorkshire House-to-House Electricity Company have agreed to supply power at the usual rate, viz., 1½*d.* per unit, if sufficient cabs are licensed.

A number of gentlemen made trips in the cab, Mr. W. C. Bersey, the engineer of the Company, acting as driver. Perhaps the severest test the vehicle was put to was ascending the stiff gradient in Cookridge Street, which was managed with the greatest ease. Those more particularly concerned in the trial took lunch together in the Queen's Hotel, Mr. Leonard W. Holmes (Messrs. J. H. Holmes and Co., electrical engineers, Newcastle), presiding. Amongst those present were Councillor Bettison (chairman of the Hackney Carriage Committee), Mr. J. W. Addyman, Mr. Bersey, and Mr. Carney (Hackney Carriage Inspector). Councillor Bettison gave "Success to the electrical cab." He said that he had ridden in the vehicle, and felt sure that it would prove a success. The manner in which it threaded its way through the traffic was quite surprising. He was satisfied that the people of Leeds would appreciate the action of his committee in doing something to secure electrical cabs for the city. He could not say that a large number of licenses would be granted to motor-cabs at present, but the committee did not intend to stand in the way of the enterprise. Of late there had been considerable agitation with regard to hackney carriages in Leeds. He thought, however, that when local cab proprietors saw that the new vehicles were being well patronised, they would change their opinion with regard to them. One of the oldest cab proprietors in the city, after examining the new cab, had advised him to endeavour to persuade his committee to license a dozen electrical cabs straight away. In conclusion, Mr. Bettison said he was certain his committee would consider any application that might be made for licenses.

The Amenities of the Cycling Press.—*Punch* has often told us what a "cycling cad" is, and has often, too, reflected the wild joys of the "scorcher" in terrifying if not injuring the harmless pedestrian. It would seem, however, that in the motor-car the "scorcher" has found a Nemesis which was not altogether expected, and the cycling Press is indignant because the scorcher is scorched at times. This is the refined way in which cycling journalism, as exemplified by the *Cyclers' News*, pours out its vials of wrath:—"*A Motor-car Hog.*—A new form of danger is threatened to road riders, and that is reckless riders of motor-cars. A couple of London cracks relate how they met a motor-car road hog along the Brighton road at Christmas, and who all but ran them down in a narrow part of the road near Crawley. In the two cracks, however, the hog had someone to reckon with; and, keeping behind the car, the two riders made the driver pull up and apologise when he arrived into the village of Crawley. Had one or the other actually been run down and hurt, it might have fared a good deal worse still with that driver." We can only say that it is difficult to judge which is the greater offender, the driver of the motor-vehicle or the scribe. The former may be safely left to the police, but as for the latter—but there, we have often remarked that good manners are not taught in Board Schools.

DOINGS OF PUBLIC COMPANIES.

AT the annual meeting of Campbells, Limited (Glasgow), on the 30th ult., the report, recommending a dividend of 10 per cent., was adopted. In answer to a shareholder, the chairman (Mr. A. I. Fortescue, of Kingcausie) said the directors were closely following the development of motor-cars, and were determined to keep abreast in the matter.

AT the annual meeting of the Girling Cycle and Motor-Car Company (Brighton) last month, it was resolved to pay a dividend of 3 per cent. for the past year on the ordinary shares. The directors explain the small dividend by stating it is owing to a wet and windy spring, ridiculous articles in the daily Press, and the large amount paid for duties, legal expenses, &c., owing to the reformation of the present Company.

London Electric Omnibus Company.

THE RESULT OF EIGHTEEN MONTHS' WORK—A COMMITTEE OF CONSULTATION APPOINTED.

THE ordinary general meeting of shareholders of the London Electric Omnibus Company was held on the 31st ult., Major S. Flood Page (Chairman of the Company) presiding.

The CHAIRMAN said:—I am very glad that the time has come at last when it is my duty to discuss with you the affairs of this Company. We have postponed the meeting as long as we possibly could, even to the limit of the legal date, because we had hoped that when we met we should be able to tell you that we had succeeded in making an alliance with a company for the building of the omnibuses, and with another company for the manufacture of the accumulators. I am glad to be able to say, with reference to the Syndicate called the Electric Street-Car Manufacturing Syndicate, that that Syndicate has now come into existence, and that I have been summoned to a meeting of the Board down in Wolverhampton on Wednesday next, for the purpose of allotting the shares which have been applied for. Now, you are aware that we have been under great difficulties, owing to our not having proper premises. It states in the report that, the amount of capital at the disposal of the directors not being sufficient to enable them to commit the Company to the expenditure necessary either for the purchase or lease of suitable premises, they have had to contract for the several portions of the omnibuses with various firms in different parts of the kingdom, the engineer then putting the parts together in London under great difficulties. We came to the conclusion, very shortly after we set to work to build the first omnibus, that it was a most difficult matter to contract for the manufacture of the various parts and put them together in London. This was instanced in the contracts required for the manufacture of the motors. We could not get any of the different contractors in the various parts of the country to agree to anything like a penal clause. We made a contract for the delivery of motors at the end of four months, and, not getting them, we were compelled to cancel the contract and start again. We, therefore, came to the conclusion that it was absolutely necessary to make some other arrangements. At the statutory meeting I said that we were not going to launch into factories, as we had not money enough. I also told you that this was a pioneer Company, and that we must of necessity move slowly. No doubt we are all disappointed that more progress has not been made. At the commencement we all believed that we should be able to make more rapid progress than we have been able to do; and yet real progress has been made. The first step is the solving of the manufacturing question, which has been the most difficult thing to contend with. As you will see by the report, the directors during several months have been negotiating for and assisting in the formation of the Electric Street-Car Manufacturing Syndicate, which was registered on the 3rd of this month, and a contract has been made between this Company and the Syndicate, in which, among other things that have been going on, it was proposed that I should accept a seat on the board of the Syndicate, and Mr. Thomas Parker, of Wolverhampton, should accept a seat on the board of this Company. The appointment of Mr. Parker to this board will materially strengthen it, as that gentleman has had a large experience of the manufacture of electric appliances. Now, how do we stand? We are the only Company in England—I am not quite sure whether we are not the only Company in Europe—that has got electric omnibuses to run along the streets without rails. We have at this present moment one omnibus which holds 26 passengers, and we have a report from our engineer, Mr. Radcliffe Ward, in which he tells us that it must be noted that the technical difficulties in successfully producing and working such a vehicle are far greater than those for small vehicles carrying a few passengers. Nevertheless, this car is under the most perfect control, and can turn in a small space, and steers with perfect ease in the most crowded traffic.

Then we have another 10-passenger omnibus, which was licensed by the police yesterday, and I may say that the 26-passenger omnibus will certainly be licensed in the present or next week. In addition to that, we have partly built another 26-passenger omnibus at Shrewsbury, and arrangements have been made with the Electric Street-Car Manufacturing Syndicate for the building of another omnibus for this Company. In the course of a very short time I hope we shall, at any rate, have one 26, one 10, and one 16 passenger omnibus running about the streets of London, in order to show what can be done in electrical traction in omnibuses. I am sorry Mr. Spagnoletti is not able to be present at our meeting; but he has written to me a letter with reference to the Sola accumulator, which he says is the best accumulator in the world. What I maintain is that in this Sola accumulator we have an accumulator admirably adapted for our purpose, and one which will give us an enormous advantage when we come to have it regularly at work in the streets. It has never failed, and, of course, you know something about the value of accumulators. I was in hopes of getting over the manufacture of the accumulator, but certain claims have been made. I have no hesitation in saying that when these claims can be adjusted—they ought to be adjusted—we shall be able to show we have got a valuable property in that accumulator. We have heard a good deal about this being a very big Company, but it is a very small Company. It never could be in a position seriously to compete with the London General Omnibus Company, we having only a capital of £50,000. (A Voice: "It ought to be £150,000.") Of that £50,000, £48,756 has been called, of which £20,000 was paid to the vendor. Now as to the future. We state in the report that all that is required is that the shareholders should work together, that a comparatively small amount of money should be provided for the immediate purposes of the business, and that there should be some alteration in the details of the Company. There is no reason for panic, least of all for winding up the Company, as has been suggested If the vendor and his associates had paid the money due on their partly-paid shares the Company would have had ample funds for immediate requirements. We also want to carry the shareholders with us. We believe that if we act in unity the foundation has been laid for a real good business; but I am quite sure that if we act in discord somebody else will inherit the work we have been doing during the last 18 months. It is for you to determine whether you choose to keep it in your hands or to leave someone else to reap the benefit. We would suggest that you appoint a committee to consult with the board on the position and requirements of the Company, and if you agree to that I have very little doubt that we shall be able to put this concern in a stronger position, and one that will give great promise for permanent success. I beg to move:—"That the report and accounts for the period extending from the registration of the Company on May 18th, 1896, to November 30th, 1897, be and are hereby received and adopted."

Mr. HENRY FOX seconded the motion.

Mr. CURTIUS was proceeding to refer to the prospectus of the Company when he was interrupted by the Chairman, who said that as legal proceedings were pending with reference to the prospectus, he was advised by the solicitors that such a matter could not be discussed. Mr. Curtius, continuing, said that in that case there was no use making any comments at all. He proceeded to say, however, that in 1888 a syndicate was formed for thoroughly testing Mr. Radcliffe Ward's system of electric traction, and that, after years of successful investigation and experimental work, it had been decided to form a company, with adequate working capital, to introduce the system into London and elsewhere. That appeared in the prospectus, he said, and he asked how far had they gone in that direction? He would also ask why the directors dared to go to allotment on the capital they did?

Mr. CONDICT also complained of the directors proceeding to allotment on so small a capital, and expressed the opinion that it was not the business of this Company to manufacture accumulators. He also objected to Mr. Parker being on the board of this Company when he was associated so directly with a business which he held was antagonistic to their own. He suggested that the omnibuses which had been spoken of by the Chairman should be at once put

I.

upon the streets of London, say from Victoria Station to Piccadilly Circus, the fare to be 6*d*. per journey. He also thought that some time should be given to those in arrear of calls, permitting them to pay up in monthly instalments. If they did not avail themselves of that privilege the shares might then be offered to the remaining shareholders. (Applause.)

After some further discussion, the CHAIRMAN, in reply, said with reference to the question of whether the shareholders who had not paid up their calls should be sued, that was a matter which the committee, which it was proposed to appoint, would decide upon. No cash of the Company had been paid into the new Company to make the Sola accumulator; it was simply a transfer of so many fully-paid shares. With regard to Mr. Parker's appointment on the board, he might say that on any question in which a director was personally interested he refrained from voting.

The resolution was then put to the meeting and agreed to.

The CHAIRMAN said he had now to move that the following shareholders be appointed to consult with the directors on the position and requirements of the Company, namely, Colonel Turnbull, Mr. Hayden, Mr. Serymgeour, and Mr. Condict, and that these gentlemen, along with the board, be requested to report to the shareholders at a special meeting to be convened within sixty days.

This resolution was unanimously agreed to, Messrs. Percy Mason and Co. were reappointed auditors, and a vote of thanks to the chairman, on the motion of Mr. Condict, brought the proceedings to a close.

Britannia Motor-Carriage Company.

THE second ordinary general meeting of the Britannia Motor-Carriage Company (Limited) was held on December 15th last, at the Britannia Motor Mills, Woodstock Road, W., under the presidency of the Hon. J. H. H. Berkeley (the chairman of the Company).

The CHAIRMAN, in moving the adoption of the report and accounts, said that under ordinary circumstances he should at once go through every item in the accounts and explain them; but the shareholders would see that the auditors had appended to the accounts what was called a qualified certificate, and he thought it best to commence by referring to their report of the 6th inst., which was alluded to in their certificate. He and his colleagues and the solicitor to the Company were of opinion that the auditors had in their report taken an entirely erroneous view of their functions and duties, and in several of the statements which they had made they had gone entirely beyond their province. In support of this opinion he quoted the opinions expressed by Lord Justice Lindley and Lord Justice Lopes to the effect that it was no part of an auditor's duty to give advice to either directors or shareholders as to what they ought to do, and that his business was to ascertain and state the true financial position of the Company at the time of the audit. Again, an auditor was not bound to be a detective, or to approach his work with suspicion or with a foregone conclusion that there was something wrong. The chairman proceeded to read the report of the auditors (Messrs. Carnaby, Harrower, Barham, and Co.), in which they pointed out that while the balance-sheet was a correct abstract of the accounts as appearing in the Company's books, its accuracy, as disclosing the true position of the Company at September 30th, 1897, was in their opinion subject to the clearing up of various matters. These had reference to the sale of patents, the absence of various vouchers and documents, and several other matters of which the chairman gave categorical explanations. He remarked that for every payment made by the Company there was originally in the office a receipt, but at the present moment several of those receipts were missing. It was not possible for him to tell the shareholders who had abstracted them from the office of the Company, but they had been wilfully abstracted, possibly for the purpose of injuring the Company. He believed the shareholders would concur with the directors in thinking that if the auditors had approached their work free from suspicion, and without having apparently arrived at a foregone conclusion that there was something wrong, they would have believed the representations made to them by the directors, in whom the shareholders had hitherto placed their confidence. Practically every entry in the books of the Company had been made by the auditors, and the accounts now submitted were made up and prepared by them, so that they should have had no doubt as to the accuracy of the balance sheet. Perhaps the shareholders would agree with him in thinking that it would have been better for the auditors to have confined themselves strictly to their own duties, instead of apparently desiring to arrogate to themselves the duties appertaining to directors and solicitors. The chairman then referred to the accounts in detail, and pointed out that the profit and loss account showed a considerable excess of expenditure over income. At the date when the accounts were closed the Company had not reached a point when it was in a position to complete the delivery of motor-carriages, consequently while the expenditure was necessarily heavy during the period covered by the accounts, there was practically no income. Shortly after the Company went to allotment negotiations were entered into for the sale of the British patents and colonial rights, and the outcome of these negotiations was that they sold the British patents and colonial rights to the British Motor Syndicate for £16,000, but they obtained, as part of the contract of sale, a perpetual free license to manufacture, sell, and use the Britannia Motor in Great Britain, Ireland, and the colonies. As part of the contract they had also placed with them orders from the British Motor Syndicate to supply them with motor-carriages to the extent of £10,000 per annum for three years, on which they were entitled to charge 35 per cent. over the actual cost price of the motor-carriages. They did not at first propose to manufacture themselves, but intended to get the motors and carriages built for them. They, however, found this most difficult; indeed, it was almost impracticable at the time, and at last they were compelled to face the fact that if they were to get the motors made satisfactorily they should have at first to make them themselves. They endeavoured to get suitable premises for their purposes in or near London on lease, but although the managing directors and the engineer visited dozens of places, they could not get one on lease, and as the premises in which they were now assembled were offered to them, they secured them on terms which were most advantageous to the Company. They were most commodious and most suitable premises, and they were now well fitted with machinery, tools, and necessary appliances. Only those who had been continually at the business, as the directors had been, could form any idea of the immense difficulties which had had to be overcome in starting an entirely new industry, in equipping the works, in getting ready the various patterns and designs, and in making the tools. Everything had been done there excepting the bodies of the carriages and the tyres. These tyres had been the cause of much trouble and anxiety to the directors, and he was not sure that they had got the most suitable ones for their purpose. Some motor-carriages were finished, and others would be completed shortly. Practically, their greatest difficulties had been overcome. But it was no use disguising from the shareholders the fact that the Company had not too much working capital left; and, although they might go on satisfactorily, it would, in the opinion of the directors, be advisable for the Company to be strengthened in some way. Consequently, they had had for some time under their consideration in what way this could be best done. At the meeting held on November 5th he informed the shareholders that there were pending, and were almost completed, negotiations for a deal by which he believed members would be very considerably benefitted. He was not able then to give particulars of the proposed deal, but he had sincerely hoped that he should have been able that day to say it had been completed. The shareholders had to thank those persons who, while pretending they had been animated by a virtuous desire to protect the interests of members, had, since the last meeting, been using the most persistent endeavours to throw discredit on the Company and all connected with it, that the deal had not yet been completed. It was hardly to be wondered at that those who were negotiating with the directors had not shown too much anxiety to complete. Draft agreements, however, had been exchanged; they had had several meetings, and there was at present only one point on which they were not in accord, and that, he believed, could be got over. Shortly, the proposals were as follows:—(1) That the Britannia Motor-Carriage Company should sell the whole of its undertaking and assets to another company; (2) that holders of shares on which 15*s*. had been paid should receive for the shares they at present held 2*s*. 6*d*. in cash per share, and one share credited with 17*s*. 6*d*. paid up in a company to be called the Britannia Electric Motor-Cab and Omnibus Company (Limited), with a nominal capital of £120,000, and a working capital of £30,000 for each share at present held; (3) that holders of fully paid-up shares should receive 2*s*. 6*d*. cash per share, and one share in the company already referred to for every share at present held. The proposed arrangements appeared to the directors to be to the advantage of every member. Practically, they amounted to this: that, if the agreements were completed, members who had subscribed for their shares would get a cash bonus of 16½ per cent. on the amount they had paid up within some 15 months of the original allotment of the Britannia Motor-Carriage Company, and get credit for another 16½ per cent., while they would obtain exactly the same holding in the new Company as they had at present in the Britannia Motor-Carriage Company, but their present liability of 5*s.* per share would be reduced to 2*s.* 6*d.* per share. The holders of fully-paid shares would get a bonus of 12½ per cent. on the nominal value of their scrip, retaining an interest equal to their former holding in the new Company. It rested entirely with the shareholders whether the directors should go on as they were at present, or whether they should endeavour to get some such scheme carried through. Of course, they could not come to a definite decision that day, but if there appeared a desire among the shareholders that the scheme should be carried through, then the directors would in due course summon an extraordinary general meeting, and submit formal resolutions to give effect to it.

Mr. BRYANT seconded the motion.

The AUDITOR (Mr. Carnaby Harrower) said that when his firm took up the audit they had to complete the postings in the books and to hunt about for vouchers, &c. The chairman had admitted that there was considerable confusion when they took the matter up, and in his (the auditor's) opinion his firm had only done their duty to the shareholders.

Mr. TIBBETTS moved, as an amendment, that the accounts be received but not adopted, in order to give the auditors an opportunity of investigating certain matters which, he said, had not been altogether answered to their satisfaction.

Mr. SIMPSON seconded the amendment.

The CHAIRMAN remarked that Mr. Tibbetts had only the previous week had five fully-paid shares transferred from the name of another member of the Company into his own name.

Mr. TIBBETTS said he had had the shares transferred into his name for the specific purpose of attending that meeting, in order to represent several shareholders.

After some discussion the amendment was rejected, and the report and accounts were adopted, with eight dissentients.

Messrs. Carnaby, Harrower, Barham, and Co. (the present auditors) were proposed for re-election, but an amendment in favour of the appointment of Messrs. Hardy, Hislop, Cleveland, and Channon was carried.

A vote of thanks to the chairman closed the proceedings.

In reference to the appointment of Messrs. Hardy, Hislop, and Co. at the above meeting, a letter from that firm appears in the current number of *The Accountant*, in which the following passages occur:—

"In the first place, our names were proposed at the meeting without any reference whatever to us on the subject, the first intimation we received of our appointment being through the medium of the financial papers, several of which contained a full report of the meeting.

"Secondly, we have not up to the present received any official notification of our appointment, and when we do we have yet to decide whether or not we shall act.

"Supposing, however, that we should accept the appointment, the shareholders may rest assured that the whole of their interests will be as strictly and as conscientiously looked after as they have been by the late auditors."

Great Horseless Carriage Company.

AN extraordinary general meeting of the shareholders of this Company was held on December 22nd last, at the Motor Mills, Coventry, Mr. H. J. Lawson presiding, for the purpose of considering the resolution for the reconstruction of the Company, full particulars of which scheme we publish hereunder.

The CHAIRMAN thought it would be a waste of time to talk about the success of the motor-car and the future of the motor traffic. He believed the present state of public opinion was very different to what it was 12 months ago; the power of motors, their speed, and the economy with which they worked were generally acknowledged. At the same time he would call their attention to two or three things which placed that matter beyond controversy. The traffic of our streets was slower and more expensive than it might be, and he could prove that to the satisfaction of anyone who disputed it. He could take them from that spot to any given spot within 20 miles quicker than a railway train could. If they wished to go from one place to another they had to walk to the railway station and when they arrived at their destination they had to walk or take a cab to their houses. With a motor-car they could go from door to door. Objections to motor-cars had been raised, and such questions had been asked as "Will it do for all sorts of roads?" "Will it go any distance and any length of time?" There was a car in that building which had been the longest journey possible in this country. It had been driven from Land's End to John o' Groats and back, a distance of 2,000 miles. It acted perfectly and kept time. Every part of it was made in those works and the Daimler Company's works. Motors had also climbed hills, and a car built in these premises had been driven up the Malvern Hills. He had received a letter from a Mr. Stirling, in Scotland, giving a long list of journeys made by motor-cars for passenger traffic. They had cars to carry eight people, which were built there. One of the greatest complaints against the board of that Company was with respect to the enormous amount of money being spent on perfecting the electric cab. But the £10,000 or £12,000 they had spent on the electric cab had produced the London electric cab.

It was the first time in the history of the world that these cabs had been put upon the streets to take traffic, which these cabs had done, to the satisfaction of everyone. They had the sole right to build these cabs, and they had received orders for 75 London electric cabs from a company a week or two ago. All the cabs the Company wanted were supplied from these works, or else they had to consent to the order being given elsewhere. Fifty cabs were being built under their patents and license by another firm, because they were not ready to do that work. (A Voice: "Then you ought to have been.") He had received letters from people who were using their vans in London, and all of them were satisfied. They started six months behind the Daimler Company, and as it was only 13 months since they started, the shareholders could hardly expect much more. They had now more orders than they could turn out, and the Daimler Company was booked up for all next year. They had 260 cars in hand. Time would also be wasted in talking about the value of their licenses and patents, and the monopoly it gave them. (Hear, hear.) The monopoly was theirs. (Hear, hear.) It would be time to talk about that when competition was severe. At the present time no one else was turning out motor-cars every week. There were one or two solitary makers who had succeeded in making cabs, but they would be pleased to run their cabs against any other make in the world. Having plenty of money and plenty of work the shareholders might say, What was the use of a scheme and a reconstruction? He would refer them to the two circulars—one from the directors and the other from the shareholders' committee. The one from the directors stated that they could do no more than they had done.

They had had a great deal of opposition, a great deal of mismanagement, to complain about, and a great deal to fight against that they ought not to have had. Instead of going over that, which would do no good to their shares or to the Company, he would turn at once to the committee's scheme. Since the committee had been sitting, clearing up the obstacles which he had to fight against, they had had a new manager, and they had been turning out and selling cars as hard as they could. Notwithstanding the enormous expense they had been earning a profit. Before the committee sat, their expenses amounted to nearly £1,000 a week, and the results were most unsatisfactory. The board consisted of men who knew nothing about the motor-car business, and some of the directors held the view that every floor of these works ought to be fitted with machinery, and started on full power making motor-cars. Against that view he and two other gentlemen were opposed, because they knew that their capital—the £40,000 they had in the bank—would have to be spent. By his determination that money had been saved. They wanted to make one pattern of motor which would suit the million and come within reach of their pockets, one which would not cost £300 or £400, but which would be simple to repair if anything went wrong. They were having built a suitable thing to sell to the crowd in quantities at about half the price that the motor-car of to-day costs. Since the committee had been sitting they had actually been making a small profit. Their expenses were reduced to about £250 a week, and their works were built and ready to receive heavy machinery. When the premises were fitted with machinery they would be able to turn out two or three dozen cars a week. The Daimler Company were turning out more cars than any other company in Europe. Their great object was to make their own motors, which were now supplied them by the Daimler Company. They should be obliged to be good customers to the Daimler Company, because that Company had all their wheels and frames, &c., from the Great Horseless Carriage Company. The shareholder who had a £10 share in the Great Horseless Carriage Company got four preference shares in the British Motor Syndicate, the parent Company, which owned all the patents—with the possibility of having to pay in the course of time 3*s.* They would have to pay 6*d.* a share down, and the further sum when they were called up. Why was it in the interests of the British Motor Syndicate or this Company that the shareholders should have to pay 3*s.* and take the four preference shares in the Syndicate?

Speaking for the British Motor Syndicate, he could assure them they hoped they would not take the preference shares. They would let them off. He would take the preference shares, and pay the 3*s.* This parent Company had a right to form as many companies and grant as many licenses as would be required. That Company had to pay the Great Horseless Carriage Company £12,000 a year in dividends. The British Motor Syndicate had great pressure put upon them before they consented to give them that for 3*s.* The reason it was done was purely on moral grounds. Some of the shareholders imagined that they had some hold on the parent Company; they also held some interest in the patents. The Company which would take the place of the Great Horseless Carriage Company had the advantage of paying a dividend on a much smaller sum than this Company would do if they went on the present lines. They would only have to pay 6*d.* immediately, and they would have 10 shares which would be much more marketable than one £10 share. It would be a superior sort of an investment compared with what they had now. It was only as an improvement that they should consider it, because they could go on on the present lines and with £40,000 in the bank, only they would not have such a good investment, and it would be much longer before they would get a realisable security. With regard to the money spent on experimenting, he did not think it had been wasted, as it had taught them a great deal. He hoped the shareholders would remember that they were speaking to their customers as well as to the public, and he hoped they would not foul their own nest and do harm to their own shares and the Company.

Mr. MACK proposed the following resolutions:—

"(1) That it is desirable to reorganise the affairs of the Company, and, accordingly, that this Company be wound up voluntarily, and that John Baker, of Chiswell House, Finsbury Pavement, chartered accountant, be, and he is hereby, appointed liquidator for the purpose of such winding up. (2) That the draft agreement marked 'A' submitted to this meeting be, and the same is hereby, approved, and that the liquidator be, and he is hereby, authorised, pursuant to Section 161 of the Companies Act, 1862, as modified by Article 131 of the Company's articles of association, to enter into an agreement with the British Motor Syndicate (Limited), in the terms of the said draft, and to carry the same into effect, with full power, nevertheless, to agree to any modification or alteration of the terms thereof as he shall think expedient either before or after the execution thereof. (3) That the draft agreement marked 'B' submitted to this meeting be, and the same is hereby, approved, and that the liquidator be, and he is hereby, authorised, pursuant to Articles 130 and 131 of the Company's articles of association, and of every other power enabling him in that behalf, to enter into an agreement with a Company intended to be formed, and to be called the Motor Manufacturing Company (Limited), or by such other name as may be resolved upon in the terms of the said draft, and to carry the same into effect, with full power, nevertheless, to agree to any modification or alteration of the terms thereof as he shall think expedient either before or after the execution thereof."

Mr. HOFFMAN, as a member of the shareholders' committee, who had taken a great deal of trouble in the matter, seconded the resolution. He explained that the committee was formed one day in town at lunch. They decided to send out anonymous circulars. They were tired of litigation. To that circular they had 1,600 replies, which showed that most of the shareholders were tired of litigation. All the large shareholders in London were written to, and out of them a certain number decided to join the committee. Amongst those written to were Mr. William Whiteley, the universal provider, and he subscribed £10,000 in this Company, and Mr. Wagner, who put £75,000 in sovereigns into the Company. He was sure that a better scheme could not have been evolved. The first scheme which was submitted was that a new Company should be formed—the Foreign and Colonial Company—that they should supply money to that Company, and that eventually they should be shareholders. That meant simply printing paper and putting their money in. That scheme was rejected, and then it was proposed they should amalgamate with the Motor Syndicate. It then took another course and became the present scheme. The objection the committee had mostly heard to the present scheme was that the Great Horseless Carriage Company had to hand over money to the British Motor. (Hear, hear.) He quite admitted the force of that objection, but shareholders must not forget that they were becoming part and parcel of that Company. He asked one of his co-members of the committee that morning whether he would rather take £12,000 a year in the British Motor or the dividends likely to be earned in future by the Great Horseless Company, and the reply was, "I think I will take £12,000 a year from the Great Horseless." In the one case there was preference and debenture interest, and in the other there was not. He admired the way in which Mr. Lawson had staked his life on this industry, and was impressed with the earnestness with which he meant to carry the business to a success. He had a large holding of some hundreds of thousands pounds' worth of shares in the motor industry, and his holding in the British Motor Syndicate was not worth a "tinker's cus" till he had paid the new Company £12,000 per annum. If the shareholders got nothing from the Motor Manufacturing Company, which was to take the place of this Company, they would not have lost their money. They, however, should get dividends in the future from the new Company, which would start without litigation. That was a great thing; it was impossible to carry on business with hundreds of law suits looming over their heads. He believed that was the reason there was not more work going on at the present time. The committee went to Paris to examine into the industry. They visited some eight or 10 factories, with 600 men in one and 400 in another, making some wonderful machinery. They were impressed with the strides that motor-cycles had made there. They were all about the streets. Since April 3,000 had been sold by one firm. When they came back they looked into the patents this Company held, and they found that they had no bicycle patent at all. They had altered that, and now they could make motor-cycles. He advised the manufacture of small, cheap things to familiarise the eyes of the public with what they were doing in Paris, and the rest would follow. By the scheme they would get for each £10 share four preference shares, 17*s.* paid, in the parent Company—the Motor Syndicate—and £1 debenture fully paid in the same Syndicate. That bore 4 per cent. interest and the preference shares 5 per cent. They also got six shares in the new manufacturing company. He did not know what the name of the new Company would be, but it would start clear of litigation with 50,000 sovereigns in the bank, and owning all the plant, which he understood had cost £22,000 or £23,000. If they only made £20,000 it would give them £15,000 a year; £15,000 and £12,000 made £27,000. That would mean over 5 per cent. on whatever they might put in. He believed the scheme was a very good one, and the shareholders ought to support it.

Mr. BARR asked for an explanation of paragraph 6 of the scheme, which said:—"The British Motor Syndicate to take over all the liabilities and litigation of the Horseless Company and all risks thereof, and in consideration of this and their other concessions receive back the rights conferred on the Horseless Company under the license and also the remainder of the assets." He also wanted to know whether the Horseless Carriage Company were the exclusive owners of the whole of these premises.

Mr. VAN PRAAGH (solicitor) said that before he dealt with the question he should like to make one or two remarks. There was a great deal of litigation going on now, and perhaps they were not aware that this litigation was being conducted, as far as this Company was concerned, entirely by one gentleman on behalf of a very small fraction of the shareholders, whom he had got together for the purpose by means of circulars. Before a solicitor could get a number of shareholders together by means of circulars he must—looking straight in the face of what he proposed to do—put into those circulars a number of statements calculated to draw to him the clients he required. In this case that course was followed. There were 3,000 shareholders in this Company, and it was not possible to get 3,000 people to entirely agree upon any one thing. This gentleman made certain statements which were so ridiculous that he only succeeded in getting a small fraction together. He said that the British Motor Syndicate had not got the patents, and he said the patents were not valid. He made a number of other statements, and the gentlemen who received the circulars did not know what to make of them. In that circular he accused everybody. He (the speaker) would ask the shareholders to deal very carefully and gingerly with any questions that might arise in their minds through this circular, and not to condemn any man until he was found guilty. They had heard a great deal about the directors, but nothing had been proved. Agreements on the formation of a company of this kind had to be framed with great care. When one had thought out every possible incident which might affect the future, one discovered that some bargain had been made which did not work so well in practice as in theory. They had to pay certain moneys, and to receive a totally different license to that granted to them. In view of that. it had been no easy task for the various solicitors to work out in a technical and legal form the scheme the terms of which the committee supplied. Mr. Barr's question could be best answered by his referring to the paragraph in the scheme headed "Present position of the Company." He would there see the terms of the license under which they had worked precluded them from making the lighter motor-car and the tricycle, from which possibly they would earn most money. Under the present license they had that power. It was originally intended that this Company should be a carriage company, and that another company should be formed for motor-cycles. It had taken months to arrange, and it was in making this new bargain that the arrangements referred to became necessary. If the one paragraph was read in conjunction with the other, they would find the explanation. In answer to Mr. Barr's second question, he replied that the whole of the premises belonged to the Great Horseless Company. The premises were negotiated for at the early stages of the formation of this Company, but, as they were not prepared to buy them at the moment they had to be bought, the promoters of this Company procured another Company to buy them in order that they might get them at the price at which they were offered. They were transferred from that Company to this.

Mr. BARR expressed himself as quite satisfied with the explanation, and said he was prepared to support the resolution. He had not taken sides with the committee hitherto because he felt that the directors ought to have ample time to develop what was a new industry. He had no doubt they had made blunders; it would be extraordinary if they had not. The committee had formulated a scheme which he thought would tend to the prosperity of the Company. He emphasised the remarks of the chairman that nothing should be said to foul their nest, and he sincerely trusted that shareholders would abstain from any kind of harsh statement.

Mr. PLAYER also supported the resolution.

Mr. REA (Blackpool) supported the scheme of the shareholders. With regard to the board of directors, he did not know whether he was speaking to any of the original directors or not, but, if so, he hoped they would put more brains into the management of the concern than they had done previously.

Mr. HODGES (Leicester) asked how many directors there were now on the board, and also how he could obtain the names of the directors.

Mr. VAN PRAAGH replied that there were five directors. The names were:—Messrs. H. J. Lawson, S. Robinson, J. H. Mace, E. J. Pennington, and T. Lambert. The articles of association insisted on their not being less than five. If it had been possible to have fewer, for the purpose of saving expense they would have done so.

Mr. HOFFMAN said he believed the committee would be represented on the board of the new Company. He had been asked to join, and he had not yet decided. The best plan would be for the committee to go on conferring with the present board; then, at the statutory meeting, the shareholders could decide who they would have and who they would not have. It was a matter for consideration whether they should be represented on the board of the Motor Syndicate.

Mr. FRANKENBURGH (Manchester) said he could not agree with the resolution at all. He would not say anything, but he was not satisfied with the whole affair from beginning to end.

The resolution was then put to the meeting, and the chairman declared it carried unanimously.

Mr. VAN PRAAGH said he thought it was desirable to have a poll in the interests of the shareholders here, and particularly in the interests of those who were represented by proxies. They had proxies for over £400,000 worth of shares in favour of the scheme. They could, therefore, reckon how many had not sent proxies at all and how many would vote against the scheme. Taking a poll was merely formal, and for a purpose which they would understand at a later date better than now.

On the motion of Mr. David (Sutton), seconded by Mr. Ramsden, a vote of thanks was given to the committee for the trouble they had taken in drawing up the new scheme.

The meeting then terminated.

THE confirmatory meeting was held on January 7th at the Motor Mills, Coventry. Mr. H. J. Lawson again presided, and Mr. J. H. Mace and Mr. T. Robinson (directors) and about 20 shareholders were present. The proceedings, which were mainly occupied by the reading of legal agreements, were purely formal, and the resolutions, on being put to the meeting, were carried unanimously.

BALANCE SHEET OF THE GREAT HORSELESS CARRIAGE COMPANY (LIMITED), 30TH NOVEMBER, 1897.

Capital and Liabilities.

	£	s.	d.	£	s.	d.

ALFRED BURGESS, Secretary.

We hereby certify, after having examined the books, accounts, and vouchers in relation thereto, that to the best of our knowledge and belief the foregoing statement is correct.

WHITEHILL AND WHITEHILL,
Chartered Accountants.

December 17th, 1897.

THE REORGANISATION PROPOSALS.

Details of the scheme are contained in the following circular, issued to the shareholders on 11th ult.:—

LOMBARD HOUSE, E.C.,
December 11th, 1897.

SIR, OR MADAM,—The committee are now in a position to communicate with you fully (or as fully as a circular will allow) upon the affairs of the above Company, and with these suggestions.

Constitution and Objects of the Committee.

You will remember that in reply to the first circular of September 15th over 1,600 shareholders, or more than half of the whole number, at once sent in their written approval of the objects for which the committee was formed; those objects being:—1. To investigate into the general position, including the litigation now proceeding. 2. To endeavour to obtain from the Promoters, the British Motor Syndicate, fair proposals for this Company's future, but to submit such proposals to a general meeting for full consideration. The members of the committee are all large shareholders; all but two have paid cash for their shares, and five of them were original applicants and allottees for cash under the prospectus in May, 1896. The committee have held a large number of meetings, and have, by themselves, or representatives, had numerous interviews with the directors and the British Motor Company's representatives; and in addition members of the committee have been to Paris and Coventry to inquire into the future prospects of the motor industry. The committee would very much like to commence by recording their views on the prospectus, but in view of the scheme referred to later on in this circular, they feel that no great benefit could arise from their giving in this circular details of the various points which have been thrashed out between them and the Promoters, and that the shareholders will be more interested in knowing what has been done for their benefit. At the same time, the committee think it necessary to record their opinion that the capital of the Company was much too large, that it has not been wisely expended, that the bargain made with the British Motor Syndicate under the promoting contract has not proved to be a good bargain for this Company, and that as matters now stand the Great Horseless Carriage Company cannot make any progress as a manufacturing company. However, there is a great deal of difference between things that may be considered unfair and things than can be proved to be absolutely illegal, and the committee, therefore, at the commencement of their investigations had to look at the matter from the following points of view:—1. Whether legal proceedings to recover £340,000, the amount invested by shareholders in this Company, would result in judgment for the shareholders. 2. Whether, if so, there is money to pay the judgments. 3. If there is any doubt on either point, then what would be the next best course. Now, with regard to the second point, it appeared at the outset that almost the whole of the money subscribed by the shareholders has been either paid to the Promoters, and by them spent in the purchase of patents, or spent by this Company at Coventry. Under these circumstances, the committee, after directing their solicitors to obtain counsel's opinion as to the first point (litigation), took steps to ascertain the real position and prospects of the motor industry, in order that, if good, they might try to obtain a better position in it.

Future of the Industry.

For the purpose of inquiring into the future of the industry some members of the committee went to Paris, where (there never having been any Government restrictions) the industry was making progress some time prior to the passing of the English Act last November. A detailed description of their visit would take up a large amount of space, but it may shortly be stated that they went over several large factories, each employing some hundreds of hands, and in most cases with the order books full for many months ahead, and preparations for large extensions to increase the output. The principal motors in use were the Daimler, manufactured for vehicles by Messrs. Panhard-Levassor and Peugeot and others, and the De Dion for tricycles, in which latter a very large business is certainly being done, and a little vehicle attachment to this tricycle to hold two people is just out and becoming popular. It was also stated that motor traction is being adopted by the French railways, postal service, and army. The members of the committee returned quite satisfied with the progress and future of the industry in France. A visit was then paid to Coventry where, though the industry is in its infancy as compared to France, still it is clear that real business has already commenced. For example, it appears that whereas at the beginning of this year there were no British motor-cars in existence, the Daimler works are now turning out several motors weekly. The Beeston Cycle Company are turning out De Dion tricycles, and the Humber Company are starting with a regular output. Further, that the Daimler Company are booked up for a long period. In London electric cabs are running satisfactorily. A mail motor-van is now undergoing long-distance tests by the Post Office. In Scotland a line of motor-omnibuses at Hamilton is working successfully, another at Blackpool, and two other lines are being opened in Scotland, the cars for which are now in course of construction. There is at present exhibited at the Stanley Show a number of motor-cars by our Company, but such cars include certain inventions which, according to our license, we have no present right to use. We are also told that the whole of the cars exhibited at such Show, also all those which have been successfully run in England, and those which have been winners of the international competitions, are made under patents which, for this country, belong to the British Motor Syndicate. There is, of course, still a great deal of prejudice to contend with, as there was with railways when they started, and also with the introduction of bicycles, but existing facts show to the committee's satisfaction that the industry has come to stay. If motor-cars can run from Paris to Marseilles, and from John o'Groats to Land's End, as has been done; if, as was personally experienced by members of the committee in Paris, a motor-car can go for miles in the dark, through the most crowded streets, at nearly double the pace of the ordinary traffic, and a full motor-omnibus can go at the rate of 12 to 15 miles an hour to the top of Mont Valerin (which is rather longer and steeper than the journey up Haverstock Hill to Hampstead Heath), and if all this can be done for a fraction of the cost of horse traction, then, so soon as motor-vehicles, with all the latest improvements, are turned out in quantity from a regular pattern, to enable them to be put on the market at reasonable prices, a motor manufacturing company should pay.

The Present Position of this Company.

Now, how far is our Company in a position to meet the above proposition? The answer is that under our present powers it is doubtful if we could make a motor-carriage to-day that would sell. We have no right to new patents since May, 1896, which are of vital importance (particularly in electricity), we cannot make Daimler motors at all, nor "De Dion" cycle motors, which, as before shown, are the two most popular motors at the present time, nor can we make any cycle motors whatsoever. The half interest which we have under our license in any royalties or sums received by the British Motor Syndicate in respect of certain of their patents appears to be a very unworkable arrangement, and at any rate we have received nothing worth mentioning from this source. Further, a great deal of our working capital has been spent, more or less, in experimental work, and at the present time, apart from our works and plant, we have a remaining cash working capital of about £39,000, against which we have liabilities, including claims in the litigation, to a nearly equal amount. The bulk of our directors have left us, and though the remaining directors contend they are now working at a profit, practically nothing sufficient for dividend purposes is being done.

Any reorganisation of the Company's affairs will, therefore, involve two propositions: first, a new board being nominated on the shareholders' behalf; and, secondly, provision for further working capital.

Under these circumstances, two schemes have been considered. The first for the entire amalgamation of interests with the British Motor Syndicate, which is a Company whose policy is directed by Mr. H. J. Lawson, and which Company claims it is in the position of controlling the motor industry for England and the Colonies; but it was felt, with regard to this scheme, that the shareholders might not approve of their assets being handed over to the control of others, and that the second scheme would, therefore, be more popular. This scheme is, shortly, to cut down the excessive capitalisation of the Company; to get back from the promoters £114,000 of the shares paid to them, thus reducing our share capital to £500,000; to reorganise our Company with a proper licence and working capital, and freedom from litigation, and further reduce its capital to £300,000. To get from the British Motor Syndicate for the difference between this £300,000 and £500,000 a preferential claim upon the British Motor Syndicate. The latter point was difficult to arrange, as provision had to be made for working capital and some inducement offered to the British Motor Syndicate to give us these preference shares, since their ordinary shares are standing at a premium in the market whilst ours are at 80 per cent. discount. It was finally arranged that the £200,000 preference shares to be given us should carry a liability of 3s. per share in consideration of their giving us in addition £50,000 debentures, fully paid, out of an issue of £100,000 debentures. The scheme is as follows:—

Scheme.

1. Mr. Lawson and the Motor Syndicate to cancel and surrender £114,080 in shares, reducing the capital of the Horseless Company to £500,000.

2. Remaining shareholders to receive the following, subject to their applying for the exchange in the prescribed form, which will be forwarded to them in due course:—

£50,000	fully-paid debentures out of £100,000 4 per cent. mortgage debentures of the Motor Syndicate, repayable in seven years, or if earlier (at Syndicate's option) with 5 per cent. bonus.
£200,000	cumulative 5 per cent. preference shares (the total issue) of the British Motor Syndicate, with a liability of 3s. per share.
£300,000	total issued shares of the new Company next referred to with a liability of 3s. per share.
£550,000	

3. The said new Company (to be formed) to be called the Motor Manufacturing Company (Limited), to carry out the objects of the Horseless Carriage Company on the basis of a reasonable issued

capital of £300,000, instead of the present excessive issued capital of £614,000.

4. The new Company to have (*a*) the present building, said to have cost £20,000; (*b*) the plant and stock; (*c*) an assured working capital of £50,000; (*d*) a universal free license to manufacture under all patents owned by the British Motor Syndicate, now or in the future.

5. The provision of £50,000 working capital is assured in the following manner:—£25,000 cash is to be transferred to the new Company's bank account from the Great Horseless Company's bank account, and £25,000 is to be obtained out of the moneys payable to the new Company on the shares, the balance (if any) going to the British Motor Syndicate, in which shareholders will remember they are entitled by the scheme to a large preferential interest.

6. The British Motor Syndicate to take over all the liabilities and litigation of the Horseless Company, and all risks thereof, and, in consideration of this and their other concessions, receive back the rights conferred on the Horseless Company under the license, and also the remainder of the assets. The litigation taken over includes actions by about 2 per cent. of the shareholders, claiming return of about £30,000 and costs. These shareholders were organised by, and are acting through, one solicitor.

7. The directors of the new Company (except two to be nominated by the old board) to be chosen by the shareholders and committee, and a director, to be named by us, to join the board of the Syndicate.

Committee's Views on Scheme.

It will be seen that by this scheme very considerable concessions have been obtained from the British Motor Syndicate. These concessions are:—1. The cancellation of £114,000 in Horseless Carriage shares. 2. The giving us £50,000 debentures and £200,000 preference shares, 17*s*. paid, of their Syndicate. 3. The universal licence.

The new Company—the Motor Manufacturing Company—will thus start with an assured working capital, clearly defined rights, and a clean sheet—clear of all the litigation and troubles of the Horseless Company, these all being taken over by the British Motor Syndicate, who intend, we understand, to take the litigation with shareholders to the House of Lords, if necessary. However, we are now clear of it. The committee would have been glad to avoid asking the shareholders to take a further liability—however small—but this is unavoidable, and is more than met by the debentures and preference shares which the scheme gives to shareholders. The new Company can, under its new license, make Daimler motors and De Dion tricycles, and every other kind of motor covered by the patents, including all future patents and improvements. The committee would suggest that the new Company start manufacturing an inexpensive motor-car for country use, the machinery, parts of which would be interchangeable and easily replaced, and also a motor-van on the same lines; and, in the Committee's opinion, there would be a considerable amount of other work which this Company could take in hand at once with the addition of a small amount of special plant, but it will, of course, be necessary in a new industry to proceed cautiously at first. Many inquiries are now being received. Pattern vehicles (now for the first time ready) are being inspected by buyers, and orders booked. In considering whether or not to accept a scheme on the above lines, the shareholders must bear in mind that the only possible alternative—namely, litigation for the recovery of the shareholders' money—is disposed of (first) by the fact that the money is nearly all spent; and (secondly) by the fact that the committee have obtained the opinions of eminent counsel, including Mr. J. Fletcher Moulton, Q.C., M.P., which are unfavourable to the chances of success in litigation and in favour of the scheme. Further, that any such litigation would have to be by personal actions by individual shareholders, many of whom (particularly small shareholders) would not care to incur the loss and risk of a law suit under any circumstances, and many others of whom believe in, and would wish to participate in any success which the motor industry may attain. It must, of course, be understood that the committee are not recommending this scheme as the best possible investment for a person about to invest a sum equivalent to the money he already has in the Horseless Carriage Company, but as the best possible means they can arrange by which a shareholder, whose money is already invested and practically lost, may have—as the committee believe he will have—a fair chance of ultimately recovering the whole of it. Practically it amounts to this: That every holder of an existing £10 share in the Horseless Carriage Company will get in exchange—

A 4 per cent. British Motor Syndicate (Limited) debenture of	£1 0 0	fully paid.
Four 5 per cent. British Motor Syndicate (Limited) £1 Cumulative Preference Shares	4 0 0	each, 17*s*. paid.
Six ordinary £1 Shares of the new Company, the Motor Manufacturing Company (Limited)	6 0 0	each, 17*s*. paid.
	£11 0 0	

So that, for a further liability of only 3*s*. per share on the above 10 shares, payable by easy instalments (no payment being necessary on application for the exchange), each £10 Horseless share will entitle the holder to exchange for the above 10 shares in addition to the fully-paid debenture. Or, looking at it in another way, shareholders get, in addition to a much improved prospect of dividends on manufacturing, nearly 2½ per cent. dividend on their money already invested, or over 15 per cent. upon the amount put up to save this money, secured by a preferential claim on the motor industry, as controlled by the British Motor Syndicate. In accordance with the committee's promise to the shareholders, this scheme will be submitted to a general meeting, which has been called for the 22nd inst. for the purpose. The committee have also asked that an audited balance-sheet shall be ready for the meeting. As the bulk of the shareholders are scattered over the country, many of them being in Scotland and Ireland, their views should be represented at the meeting, and with this object the committee enclose a form of proxy, which, if it is to be of any use, must be returned to the committee and received by them not later than the 18th inst., and they earnestly ask each shareholder in his or her own interests, if not in return for the time and trouble they have given to this matter, to make a point of strengthening their hands at such meeting, by returning this proxy as asked without fail, and as soon as the resolutions are passed and confirmed the shareholders will receive the necessary forms for exchange of their shares as explained.

We remain, yours faithfully,

THE GREAT HORSELESS CARRIAGE SHAREHOLDERS' COMMITTEE.

F. OFFOR, *Secretary*.

The members of the Committee are:—

		In shares.	
M. H. Buckea	.. .. .. holder for cash of	£2,500	And also representing over one-half of the shareholders.
T. C. Boorn	.. .. .. " "	£1,000	
S. De Brath	.. .. .. " "	£400	
R. Hoffman	.. .. .. " "	£500	
C. Mann	.. .. .. " "	£1,000	
Norman Tronson	.. holding and representing	£6,000	
R. Wheeler	.. .. " " "	£1,300	
F. W. Woodhouse	.. .. holder for cash of	£1,000	
J. W. Wagner	.. .. .. " "	£7,500	

Also approve of the scheme.

Accompanying the circular was a slip to the following effect:—

With regard to those shareholders in the Company who have commenced litigation, and who by so doing have individually incurred liability for the costs of numerous firms of solicitors representing the 11 defendants being sued, the committee have been able to make arrangements whereby any of such shareholders wishing to take the benefit of the scheme referred to in this circular in preference to the delays, expense, and risks of litigation, may, by communicating to that effect to the committee before the general meeting, be relieved of any liability as to costs, and have their actions ended free from such liability. Further than this the committee cannot take any responsibility in the matter.

It should be pointed out that the bulk of the committee being, like yourself, original subscribers for shares, had the same right to bring actions as yourself if they had thought it worth while.

MR. W. J. Hunter, the solicitor acting on behalf of the dissentient shareholders in the Great Horseless Carriage Company (Limited), replied to this circular by sending the following communication to his clients:—

24, FINSBURY CIRCUS, LONDON, E.C.,
December 15th, 1897.

Great Horseless Carriage Company (Limited).

DEAR SIR,—I have just received a copy of the circular, dated the 11th instant, sent out by the "Shareholders' Committee," recommending the adoption by the shareholders of the scheme therein set forth.

Under this scheme, a shareholder assenting thereto would have to pay a sum of 30*s.* on every share now held by him, and would receive in exchange—what?

The answer is, four £1 shares and one £1 debenture of the British Motor Syndicate, and six £1 shares of the proposed new Company, to be called the Motor Manufacturing Company (Limited).

In view of the state of affairs disclosed by the recently-issued balance-sheet of the British Motor Syndicate, and of the fact that many actions are now pending against that Company, the value of its shares and debentures would appear to be nil, and as the proposed new Company would practically entirely depend upon the success of the British Motor Syndicate, it is difficult to see how its shares could have any greater value.

The result of agreeing to the scheme would, therefore, be, in my opinion, the throwing away of good money after bad, as you would be paying 30*s.* on your present shares, and receiving in exchange paper probably of no greater market value than the shares you now hold.

The committee's views on the prospects of litigation are somewhat curious. It will be observed they give no answer to the first point into which they say they inquired—namely, as to whether legal proceedings would result in judgment for the shareholders. They merely say that it appeared that the Company had spent most of its money, and entirely ignore the fact that the plaintiffs in the pending actions look more to the personal liability of each of the original directors for the satisfaction of their claims than to any remaining assets which the Company may possess, and further these plaintiffs are not seeking to recover £340,000, but only about a tenth of that amount.

The opinions of counsel referred to in a later portion of the circular as being unfavourable to the chances of successful litigation are obviously dependent upon the nature of the case and facts submitted for their consideration, and I have little doubt but that if all the facts as known to me were submitted to the same counsel, their opinions would be different.

The threat about taking the litigation with shareholders to the House of Lords, and the green slip inserted offering to relieve the same shareholders from all liability as to costs if they will only be so good as to agree to the proposed scheme, can only serve to call to mind certain other circulars which you have lately received (ostensibly from another quarter), also intended to induce you to abandon the apparently much dreaded litigation.

I can only advise all my clients to pay no attention to these new proposals, and above all to sign no proxies; but to proceed resolutely with the pending actions as the only practical means of recovering their money.—Yours faithfully, WILLIAM J. HUNTER.

A meeting was then called of the dissentient shareholders, which was held on December 30th, the following being a summarised report of the proceedings sent out by Mr. Hunter accompanied by his letter immediately following, dated January 3rd, 1898:—

24, FINSBURY CIRCUS,
LONDON, E.C.

Great Horseless Carriage Company (Limited) Shareholders' Combination.

Report of Meeting of Plaintiffs, held at Anderton's Hotel, Fleet Street, on Thursday, December 30th, 1897.

In response to the notice convening the meeting, a representative gathering of members attended, several coming from such distant centres as Nottingham, Bradford, Edinburgh, and elsewhere.

The meeting being of a strictly private character and in the nature of a conference between counsel (Mr. W. J. Disturnal), solicitor (Mr. W. J. Hunter), and clients, or their private solicitors, no professional reporter could be admitted, and consequently a verbatim report of the proceedings could not be furnished, nor would it be in the interest of the members that such a verbatim report of many of the statements made at the meeting should be given the publicity necessarily involved in sending out this intimation of what took place.

Mr. Hunter explained that the meeting was called to consider and decide as to what would be the best course for the members to adopt in view of the reconstruction scheme recommended by the "Shareholder's Committee" having been carried, and of the effect of Mr. Samuel Green's circular and the committee's offer inducing members to withdraw their actions. He stated that only 10 out of the 93 members had notified him of their intention to agree to the scheme and of their desire to withdraw from the litigation. After stating what he had learned as to the origin and formation of the "Shareholders' Committee," Mr. Hunter called upon Mr. Disturnal, the counsel, who from the beginning had advised in these proceedings and also in the actions against the British Motor Syndicate, to address the meeting.

Mr. Disturnal then proceeded, in an exhaustive speech of over an hour's duration, to explain the legal position of the plaintiffs in view of the reconstruction scheme, and the grounds for believing the actions, if continued, would succeed, and to discuss the proceedings of the "Shareholders' Committee," the manner in which it had conducted its investigations, the scheme recommended by it, Mr. Lawson's statements at the general meeting as given in the printed report sent to the shareholders, the financial position of the British Motor Syndicate as disclosed by its balance-sheet recently issued, the chances of success of the new Company under its proposed new licence, Mr. Moulton's opinion, and other matters, and then intimated that there were three courses open to the members to adopt, namely, the following:—

1. To proceed with the pending actions.
2. To withdraw the actions, and assent to the reconstruction scheme.
3. To withdraw the actions, refuse assent to the reconstruction scheme, and so treat the money paid for their shares as lost.

It was not, he explained, within his province to advise upon anything that was in the nature of a speculation; he could only advise upon the legal aspects of the questions at issue, and leave it to the members themselves to decide, as business men, what, after the explanation they had listened to, would be the best course for them, under the circumstances, to adopt.

Discussion by the members was then invited, and several members expressed their views in favour of continuing the litigation. Some questions were put, and answered by Mr. Hunter or Mr. Disturnal, it being explained, in answer to one question, that if the actions were continued, and proved unsuccessful, the plaintiffs would not then be able to fall back upon the reconstruction scheme and accept the new shares. They must definitely elect to adopt one course or the other.

Mr. Hunter read some letters he had received from some members who were unable to attend the meeting, in which they gave their opinions and offered suggestions. He also pointed out that in one respect the reconstruction scheme might be of advantage to the members if they should decide to continue the litigation, in providing funds to meet the plaintiffs' claims, should they be successful.

Mr. Hunter then took the opportunity of expressing his thanks to Sir H. A. White for the great assistance the latter had been to him in helping him to reply to the personal attacks made upon him in certain circulars issued by the defendant Company.

Sir Henry Arthur White, in reply, stated that he was very pleased to have been of any service in the matter of the unwarranted attacks in question, and that he felt quite satisfied with the manner in which Mr. Hunter had conducted the litigation. He then advocated the continuance of the actions, and expressed his opinion that the proposed new shares would be practically worthless. He was also of opinion that the members present, having had the advantage of hearing Mr. Disturnal's able explanation on many important points affecting the decision to be arrived at, were in the best position to form a correct judgment on the matter, and that therefore the decision should be taken on the vote of that meeting.

After some further discussion, and consideration of the terms of the agreement signed by each member on joining the combination, whereby it appeared that each signatory could be compelled, notwithstanding any notice of withdrawal, still to contribute his agreed proportion of the costs, a resolution to the following effect was proposed by Sir H. A. White, seconded by Mr. De Hersant, put to the meeting, and carried without a single dissentient vote:—

Resolution.

That the members of the combination of shareholders taking action against the Great Horseless Carriage Company (Limited), and its directors, as represented by the members present at this meeting, called for the purpose of arriving at a final decision as to the best course to be pursued by the combination in regard to withdrawing or proceeding with the pending litigation, are of opinion that such litigation be proceeded with and that it be resolved accordingly.

The proceedings then terminated.

The above is a correct and fair report of the proceedings at the above-mentioned meeting.

(Signed) HENRY A. WHITE.
WILLIAM J. DISTURNAL.
WILLIAM J. HUNTER.

24, FINSBURY CIRCUS, LONDON, E.C.,
January 3rd, 1898.

Great Horseless Carriage Company.

DEAR SIR (or MADAM),—I now enclose report of the meeting held at Anderton's Hotel on the 30th ult., from which you will see that the decision arrived at was not to accept the reconstruction scheme, but to continue the actions.

It appears that certain forms for the exchange of the shares under the scheme are to be sent to the shareholders after the confirmatory meeting on the 7th inst. Probably the non-signature of such forms would be sufficient indication of dissent, but as the new shares carry a substantial liability, it would be advisable, to avoid any question as to silence being an acceptance, for each member to write to the secretary immediately on receipt of this letter, giving formal notice of his dissent, as follows, viz. :—

"I hereby give you notice that I do not approve of the resolutions passed at the extraordinary general meeting of your Company on the 22nd December last, and do not propose to accept the new shares to be issued under the scheme."

Address it to Alfred Burgess, Secretary, Great Horseless Carriage Company (Limited), 47, Holborn Viaduct, London, E.C. Keep a copy of your letter, and send it, or another copy, to me.

As to those few members who have been induced to sign a consent to the withdrawal of their actions, or any proxy in support of the scheme, I can only advise them to preface their letter with a notice that they cancel such withdrawal or proxy, on the ground that it was signed by them under a misapprehension of their position. They should also send a similar letter to the Shareholders' Committee, Secretary, F. Offer, Lombard House, E.C.—Yours faithfully,

WILLIAM J. HUNTER.

The following is an interesting letter in regard to this reconstruction scheme :—

SIR,—From the secretary's account of the meeting at Coventry on the 22nd ult. of the Great Horseless Carriage Company one might think that the entire body of the shareholders in this Company followed Mr. Lawson and the self-constituted committee of shareholders like a flock of silly sheep. Naturally, nothing was said about the protests received from those shareholders who knew a little more than Mr. Lawson chose to tell them. Mr. Lawson's solicitor told the meeting that the litigation against the directors had been got up by the plaintiff's solicitor by means of circulars. This is absolutely incorrect. I was at pains to find the solicitor who was already acting for another shareholder, in order to put my action into his hands. But even at this late hour I would gladly withdraw from this action if there was the slightest chance of the proposed scheme of reconstruction saving any appreciable part of the money I was foolish enough to subscribe to this Company. I object to the proposed scheme on the following grounds :—(1) Because Mr. Lawson is still to be on the board, and had even the effrontery to take the chair at the meeting. (2) Because the committee was never appointed by the shareholders, and did not make an honest attempt to carry out their programme by seeing the plaintiff's solicitor, and in other ways allowed themselves to be laid open to the suspicion of working in Mr. Lawson's interests. (3) Because the proposed debentures in the British Motor Syndicate, a draft of which I have seen, are not worth waste paper, as they permit the holders of three-fourths of their value to withhold the interest. Mr. Lawson himself already holds something like half, and the remaining quarter required will not be difficult for a gentleman of his talents to command. (4) Because from a sentence in Mr. Lawson's speech I gather that the new Company, like the old, will be bound by an agreement with the Daimler Company not to make the motors, for the right of making which half a million was paid. This is, of course, apart from the general want of confidence inspired by the proceedings of this precious committee. *Timeo Danaos et dona ferentes.* I therefore remain among the considerable body of sensible shareholders who prefer recovering their money at law to entrusting Mr. Lawson with any more of it. It is no affair of ours that some of the shareholders have been foolish enough to cut themselves off from this remedy, but one cannot help feeling sorry for them. It would be still worth their while to insist upon inspecting the debenture form at the statutory meeting on the 7th.—I am, &c., B. H. THOMSON.

January 3rd, 1898.

British Motor Syndicate.

AN INGENUOUS (?) OFFER FROM MR. H. J. LAWSON.

We understand, says the *Financial Times*, that a communication to the following effect has been received by shareholders in the British Motor Syndicate, or Company, from Mr. Harry J. Lawson :—

The British Motor Industry,
Harry J. Lawson.

40, HOLBORN VIADUCT, E.C.,
November 27th, 1897.

DEAR SIR,—I have pleasure in enclosing you herewith debentures representing 20 per cent. on the shares held by you, which please accept on the terms of the within receipt.

You will, of course, understand that the debentures only become your property upon your signing and returning me, per return post, the within receipt, otherwise you must return the debentures.—Yours faithfully, HARRY J. LAWSON.

The form of receipt referred to is as follows :—

THE BRITISH MOTOR COMPANY (LIMITED).

Debenture Receipt.

Received, the sum of £ in 4 per cent. debentures, in consideration of which I give you a call or right to buy the shares already held by me in the British Motor Company (Limited), during the next 12 months, at the price paid by me for the same, in addition to 20 per cent. premium thereon as profit, such price and premium to be paid to me in cash, this arrangement being in accordance with a statement made at the general meeting, the report of which I have received and read.

The price paid by me for my shares was

Dated this day of 1897.

To Harry J. Lawson, Esq.,
40, Holborn Viaduct, E.C.

The debenture bond which accompanies the above documents declares that "The Company hereby charges with such payments (of principal and interest) its undertaking and all its property present and future, but not including its present or future uncalled capital, if any." Several conditions are endorsed on the bond, the following one being of particular importance :—

The holders of three-fourths in value of the outstanding debentures of this series may sanction any agreement with the Company for any modification or alteration of the rights of the holders of debentures of this series, as a class, including the release of any property charged thereby, and any postponement of the time for payment of any moneys secured thereby, and any increase or reduction of the rate of interest. And an agreement so sanctioned shall be binding on all the holders of debentures of this series, and notice thereof shall be given to each debenture holder, and each debenture holder shall be bound thereupon to produce his debentures and, if necessary, deliver up all the coupons for any interest then due or to become due thereon, and to permit a note of such agreement and the sanction thereof to be placed on such debentures. If the said coupons or any of them which may be so delivered up as aforesaid shall be cancelled, the Company shall issue fresh coupons, if necessary, so as to give effect to any such modification or alteration of the rights of the holders of debentures of this series as may under the provisions of this clause be sanctioned.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

	Capital.
Automobile Proprietary, Ld. 20 members, each with £1 liability.	
Boulton and Paul, Ld. (Rose Lane Works, Norwich) ..	£128,000
Chitty Dynamo and Motor Co., Ld. (St. George's House, Eastcheap)	200,000

	Capital.
Dublin Carriage and Rubber Tyre Co., Ld. (39, Mountjoy Street, Dublin) (Irish Company)	£25,000
Electric Hansom Cab and Carriage Syndicate, Ld. (28, Brook Street, Grosvenor Square)	2,000
Electric Street-Car Manufacturing Syndicate, Ld. (Wolverhampton)	25,000
F. Jackson and Co., Ld. (77, Oxford Street, W.)	5,000
Glasgow and West of Scotland Motor-Car Co., Ld. (180, Hope Street, Glasgow) (Scotch Company)	10,000
Henry White and Co. Ld. (Pontymister Works, Newport, Monmouthshire)	50,000
Holden Juvenile Cycle Co., Ld. (61, Caldmore Road, Walsall)	3,000
Hydro-Pneumatic Traction Syndicate, Ld..	3,000
International Steam Carriage Syndicate, Ld. (18, Hertford Street, Coventry)..	1,083
Middlesex Railways Extension (Motor Scheme) Ld. (40, Holborn Viaduct)	100
Northampton Cycle Traders' Association, Ld. (18, Market Square, Northampton)	250
Patent Folding Perambulator Co., Ld.	10,000
Preston and Beck, Ld. (Birmingham)	11,000
Rippingille's Albion Lamp Co., Ld. (Birmingham) ..	50,000
Thomas Kendrick, Ld. (Birmingham)	70,000
Turrell Motor Manufacturing Co., Ld. (40, Holborn Viaduct)	10,000
Ulster Carrying Co., Ld. (12, Queen Street, Belfast) (Irish Company)	2,000

ANOTHER VESTRY ON MOTOR-VEHICLES.

On December 16th, at a meeting of the Vestry of St. George, Hanover Square, a discussion took place on the question of motor-cars. Colonel Sir Howard Vincent, M.P., moved that it be referred to the Committee of Works to consider the application of electric or motor traction for the service of the parish. The hon. member said the Vestry had of late wasted a good deal of time in discussions with reference to the purchase of horses. He thought motor traction would prove a good substitute for horses in the parish, at least there would be no harm in trying the experiment. Major Skinner seconded the motion, and in supporting it Mr. Owen-Smith remarked that the time was speedily coming when it would be the most common thing to see a motor-car, and the most uncommon thing to see a horse. Mr. Tolley strongly opposed the introduction of motor-cars into municipal life in the interests of the farmer. He thought it was a very serious matter to attempt to destroy the very thing the farmer mainly relied upon for a living, particularly in view of the recent appeal to Parliament for help on behalf of those suffering through agricultural depression. What would become of the straw? (A member: "Use it in straw hats.") Colonel Ogilvy said the dangers of the streets of London were already very serious for poor old people, and he should certainly vote against increasing those dangers. Major Grimstone said he would much rather have horses than motor-cars, but he could not help thinking that the adoption of motor traction would be to the advantage of the Vestry. He thought, however, that motor-cars would cause the Vestry much more troublous discussion than horses had ever done. The motion was finally carried by an overwhelming majority. We congratulate Colonel Sir Howard Vincent and his colleagues. Poor Mr. Tolley! poor British farmer! whose "last straw" cannot break the motor camel's back.

Death of M. Roger.—We regret to hear of the death of M. Roger, the well-known manufacturer of automobiles. For the last three months M. Roger had been laid up with an attack of paralysis, and had to give up all work. He was born in 1850. After acting as engineer in the celebrated Cail Engineering Works, he, in 1883, started as a maker of gas-engines. He introduced the Benz motor for automobile purposes, and did much to popularise automobilism. He was the first one to drive n petrol motor in Paris. He was an original founder of the Automobile Club, and was generally most highly esteemed by all who came into contact with him.

!" Cuando escribe, refiérese Al "The Automotor and Horseless Vehicle Journal."

CONTINENTAL NOTES.

There will be an automobile exhibition at Turin in July next.

There will be an International exhibition of automobiles in St. Petersburg in 1899.

La Compagnie Nationale d'Automobile has been formed in Paris with a capital of £1,080.

It is said that the sales in France of the De Dion motor-tricycle have amounted to £30,000.

The Peugeot Company is busy on a nice little order for 150 motor-vehicles, each of 3½ H.P.

It is proposed to establish a service of automobiles from Konakry, a French coast port in West Africa, to the Niger.

The Automobile Club Belge has arranged a concours for June 26th next, and have voted £800 for the expenses of the festivities.

Another automobile Company has been established, viz., the Société Industrielle des Véhicules Automobiles, with a capital of 100,000 francs.

M. Leon Bollée is constructing a remarkable voiture. It will be of 12-15 H.P., and will weigh 700 kilos. There are no less than 10 changes of speed.

Le Chemin de Fer to Orléans is the latest railway to adopt petroleum automobiles for suburban parcel delivery service. When will our behind-the-times railway and cartage companies awake out of their lethargy?

La Salle Wagram, as an exhibition of automotors, must be classed in the same category as our Agricultural Hall—as a fiasco. There are very few motor-vehicles to be seen and little to be learnt about automobilism.

We are obliged to our excellent contemporary *La France Automobile* for reproducing in its issue of January 8th Dr. Clarke's weather table from The Automotor Pocket-Book. Our contemporary might have mentioned, however, its source of information.

It is curious to observe that both English and French shipowners take a great interest in automobilism. In Great Britain two well-known shipowners Mr. A. L. Jones and Mr. A. Holt are keenly interested in automobilism, while in France the President of the Republic, himself a shipowner, has done much for automobilism. We now notice that another distinguished French shipowner, M. Fraissinet, of the well-known Fraissinet line of steamers, is on the committee for the Marseilles-Nice concours.

The lot of the Paris automobilist is like a policeman's—not a happy one. He has to carry about a whole portfolio of documents in which the French official so much delights. Nothing in France can be done without the inevitable document. Among the mass of official literature that the automobilist has to carry and produce on demand are documents giving the weight of the vehicle and weight per axle, description of the motor and specification, method of supplying the power, description of brakes, name and place of abode of makers, official tests of motor, official number, employment of the machine, district in which it is intended to be used, the place where it is kept, two photographs, certificate of birth of the owner, and certificate of residence. Really, this is not enough. We would suggest to the Paris municipal authorities the desirability of compelling the unfortunate automobilist to have two photographs of his dog, together with the authenticated pedigree of the latter; also the abode of the proprietor's washerwoman, and a certificate of M. Le Maire to the effect that he was not in debt.

LAW REPORTS.

Great Horseless Carriage Company.

SHAREHOLDERS' APPEAL DISMISSED.

IN the Court of Appeal on the 16th ult., before the Master of the Rolls and Lords Justices Chitty and Vaughan Williams, judgment was given on the appeal of Mr. De Hersant from an order made by Mr. Justice Kekewich on November 26th in connection with the Great Horseless Carriage Company (Limited), refusing to grant an injunction restraining, until the trial or further order, the defendant Company, its directors, managers, or officials from executing or from proceeding with negotiations for a proposed agreement for transfering the assets of the Company to the British Motor Syndicate (Limited). Mr. Disturnal appeared for Mr. De Hersant, whilst the Great Horseless Carriage Company was represented by Sir Edward Clarke, Q.C., M.P., Mr. J. F. Moulton, Q.C., Mr. Warmington, Q.C., and Mr. Kirby.

In the course of his argument, Mr. Disturnal said the defendant Company was promoted in May, 1896, by the British Motor Syndicate, with a nominal capital of £750,000, divided into 75,000 shares of £10 each. The object of the Company, as defined by the prospectus and the memorandum and articles of association, was to take over the licence to use certain patents which were said to belong to the British Motor Syndicate promoters; and the consideration to the British Motor Syndicate for the licence to use those patents was the sum of £500,000, divided into £250,000 in cash, and £250,000 in fully paid-up shares of the Company. The prospectus was duly issued, and, amongst others, Mr. De Hersant applied upon the faith of it for shares, which were allotted to him. He (Mr. Disturnal) might tell their lordships that upon the prospectus about £300,000 was allotted to the public, in addition to the £250,000 paid-up shares to the British Motor Syndicate. There were now about 90 actions pending against the Company and against the directors in respect to the fraudulent statements contained in the prospectus, and Mr. De Hersant was one of the plaintiffs. These actions were for damages for fraud, or in the alternative to set aside the allotment and return the money in respect to the shares. The plaintiff held 60 £10 shares, all fully paid up. The British Motor Syndicate was what was called a one-man company. It belonged to Mr. Lawson, and to Mr. Lawson alone. The capital of the Company at one time was £150,000, and of that Mr. Lawson had 147,993 shares, whilst a Mr. Sturmey had 2,000 shares, leaving six or seven more, which were held by somebody else. All those shares were fully paid up, and were issued to Mr. Lawson and Mr. Sturmey in consideration of the assignment by them of certain patents to the British Motor Syndicate. In August, 1896, a special resolution of the Syndicate was passed to increase the capital from £150,000 to one million sterling. On October 21st an agreement was entered into between the British Motor Syndicate and Mr. Lawson. By the first clause that gentleman purported to assign to the British Motor Syndicate six patents which he said belonged to him. Then, as to the third clause, that stated that the consideration of the sale contemplated by the agreement should be £750,000, which should be paid and satisfied by the allotment and issue to the vendor or his nominees of 750,000 shares of £1 each, which said shares should be created and be for all purposes as fully paid up. Then Clauses 4 and 5 provided that an account should be taken of the assets of the Syndicate at the date in question, and that the balance of the assets should be divided amongst the original holders of the capital in the Syndicate, to the exclusion of the people who were to subscribe to the new capital about to be issued. Then Clause 6 provided that the holders of the 750,000 shares, which were about to be issued in pursuance of the agreement, should not be entitled to participate in any distribution in cash or shares in pursuance to Clauses 4 and 5. Their lordships would see, therefore, that under that agreement Mr. Lawson was to get £750,000 of the new capital and the balance of the old as being practically the only shareholder in that one-man company. For that he assigned to the Company five patents, which the learned counsel said he would not discuss the value of, but they were sworn to be of no commercial value. As a sample of them, one was a sort of gipsy's caravan, to be built of steel, to be driven by a motor fixed underneath.

On the 26th ult. an order was made by Mr. Justice Kekewich, in connection with the Great Horseless Carriage Company (Limited), refusing to grant an injunction restraining, until the trial, or further orders, the defendants from executing or from proceeding with negotiations for a proposed agreement for transferring the assets of the Company to the British Motor Syndicate (Limited). The plaintiff now appealed against that order of the learned Judge, and counsel submitted that, under all the circumstances, their lordships should uphold the appeal.

Sir Edward Clarke, on behalf of the defendants, contended that there was no suggestion that Mr. Lawson was using unfair and improper means. It was not suggested that he should be restrained from voting in respect to his shares, and the Company was entitled to do as it pleased. There was only a comparatively small interest in the Company attached to the appellant.

Lord Justice Chitty asked where the contract was, if any, that showed the scheme.

Mr. Warmington, Q.C., said there was no scheme. In comparing the positions of plaintiffs and defendants, he contended that Mr. Hersant could only sue as a shareholder. He, however, as long ago as June last, commenced an action for decision upon the ground that in equity he was not a shareholder. The action was brought upon an affidavit which showed the object of the action, and he (the learned counsel) was now taking the affidavit to be true. The affidavit itself put forward the case of the plaintiff, and what was it? That the Great Horseless Carriage Company had an assessment of £50,000, and that that sum would be, but for certain proceedings, available to the plaintiff and those associated with him to answer the plaintiff's claims. It was not put forward that there was anything *ultra vires*, which was the usual thing in the case of shareholder against company. Then, again, could anyone read the affidavit in question to mean that this application was made on behalf of the shareholders as a body? The plaintiff was really seeking to get an embargo placed upon the assets. The action was really brought by a shareholder (admitting that he was a shareholder) for an injunction, and the object of the injunction was to keep in the coffers of the Company the sum of £50,000. But what was that for in reality? Was it for the benefit of the shareholders? No; on the contrary, it must be transparent to the Court that it was merely to answer claims by persons who said they were not shareholders.

The Master of the Rolls, in giving judgment, said that a great many topics had been touched upon as to which he did not propose to say anything; and in particular he did not propose to express any opinion upon the propriety of the proceeding sought to be restrained. From a legal point of view there was one clear and short answer to the suit, and that was that it was not brought by the plaintiff in the character in which he purported to sue. Upon that ground alone the appeal ought to be dismissed.

Lord Justice Chitty concurred. He said the plaintiff was suing not for the benefit and in the interest of the shareholders, but of those who had brought actions to recover a large sum of money from the Company.

Lord Justice Vaughan Williams also agreed.

The appeal was, therefore, dismissed with costs.

Bankruptcy Court.

A SITTING of the London Bankruptcy Court was held on the 11th inst. before Mr. Registrar Linklater for the public examination of Charles Nigel Stewart, 39, Victoria Street, Westminster, whose accounts show liabilities £13,566, and a deficiency of £11,532. Under cross-examination by the Official Receiver the debtor stated that in 1895 he became chairman of the Universal Electric Carriage Syndicate (Limited), whose patents and stock were sold in the following year to the British Motor Syndicate (Limited). The last-named Company formed a branch Company in May, 1896, entitled the Great Horseless Carriage Company (Limited), and witness acted as manager at a salary of £300 a year until last June, when he resigned, owing to disagreements with one of the directors. He was afterwards connected with other companies. Witness attributed his insolvency to embarking on enterprises of which he had no previous knowledge, to Stock Exchange speculations, and to his liabilities in connection with the British and Continental Syndicate (Limited) and the Lombard Financial Syndicate (Limited). The examination was concluded.

The Danger of Restive Horses.—On December 11th an inquest was held at the St. Clement Danes Vestry Hall on the body of James Taffy, aged 38, a cab attendant, lately residing at 12, Gee's Court,

M 2

Oxford Street, who was fatally injured by a cab on November 19th. Mrs. Hettie Meyer, landlady of the Red Lion, Clarges Street, Piccadilly, stated that on the evening mentioned the deceased was minding the horse attached to a hansom cab outside her house when some friends of hers arrived in a motor-cab. The latter made the horse very restive, and some minutes later the animal bolted, causing the deceased to fall. He was taken to St. George's Hospital, but he failed to disclose the nature of his injuries. On the 4th inst. he went into King's College Hospital, where he died on Thursday. The medical evidence showed that death was due to blood poisoning, the result of the injuries, and the jury returned a verdict of "Accidental death."

Claim for the Repair of a Motor-Car.—At the Bradford County Court on January 4th, before his Honour Judge Bompas, Q.C., Messrs. S. Clayton and Co., Paradise Street, engineers, sued the Yorkshire Motor-Car Company, of Bradford, to recover £13 10*s.* 7*d.* for work done. Mr. Freeman appeared for the plaintiffs, and Mr. J. V. Curry for the defendants. It appeared that in July last the motor-car called the Victoria was sent to the plaintiffs' works to be repaired. The plaintiffs said that the car was of German make, and parts of it which required renewal, being unobtainable in England, had to be specially made. When the car was returned it was found that one or two things had not been put right, but these were subsequently remedied. For the defendants it was contended that the work was not done according to contract, and though a man was afterwards sent to effect the necessary repairs, the motor-car would still not run satisfactorily, and was ultimately repaired by the defendants' own men at a cost of over £8. His Honour, after hearing evidence on both sides, gave judgment for the plaintiffs on the claim, and for the defendants for £4 on the counter-claim.

An Object Lesson Illustrated.—Louis Tetlow, motor-carman, employed by the London Motor Van and Wagon Company, of 86, Chiswell Street, E.C., appeared on a summons at the City Summons Court, on the 11th inst., for driving a motor-car to the common danger of the public. The evidence was very clear that at 10.50 a.m. on the 3rd inst. Mr. Douglas Graham, merchant, of 2, Copthall Buildings, City, was passing through King William Street with Mr. Chadick, railroad builder, of Suffern, New York. He was telling his friend how admirably the City police regulated the traffic, and pointed to Police-constable Jefferies, 688, who was performing that duty opposite St. Swithin's Lane. Suddenly Jefferies made for the pavement, but a motor-car, driven by Tetlow, was too quick for him, struck him, and sent him heavily to the ground. Defendant pulled the car up in the space of about 10 yards, and said he sounded his horn for the policeman to get out of the way. The pace, it was said, was about 10 miles an hour; the horn was not sounded till about six or eight yards from the officer, who could have been easily avoided, but the car was kept in the centre of the road. The officer was not seriously injured. The defence was that the pace was five miles an hour, the horn was sounded 20 yards from the policeman, and the car would have been pulled up sooner, but the asphalte was "greasy." Mr. Alderman Strong said this car was going at a pace that was too rapid for the traffic of the street. He must hold the case proved, but, on the other hand, he did not wish to inflict the severe penalty laid down for this class of vehicles. He thought the justice of the case would be met by a fine of 10*s.* and costs.

A Policeman on Speed.—At Bow Street, on December 22nd, Mr. Robert Hankinson, of 35, Ferndale Road, Brixton, appeared, before Sir James Vaughan, to a summons charging him with unlawfully driving a locomotive—namely, a motor-car—at a speed greater than was reasonable; and dangerous, having regard to the traffic on the highway on which it was being driven, contrary to the regulations made under the Locomotives on Highways Act, 1896. Police-constable 256 E stated he saw the defendant driving a motor-car on the Embankment, near the Temple Station, at the rate of about 10 miles an hour. He called upon him to slacken his speed, but he took no notice. A cabman had to pull his horse on the footpath to avoid a collision, and foot passengers had to scatter right and left. The defendant (who had some gentlemen with him) said he did not think he was doing any harm. The motor appeared to be driven by electricity. The defendant now said he was driving an oil-carriage, which might be driven at fixed speeds—four, seven, or 13 miles an hour. These were definite speeds, but the motor might be driven at almost any speed. When he was spoken to by the constable he was driving at the second speed, or seven miles an hour. As a rule, a motor-car appeared to outsiders to be going at a greater rate than it really was, owing to the absence of a horse. Sir James Vaughan thought the defendant must have made some mistake as to the rate at which the car was going, and imposed a fine of 10*s.* and costs. It was stated that this was the first case of its kind decided in London.

"Chuting" with a Motor-Car.—Oliver Bush was summoned at the City Police Court for driving a motor-car to the common danger of the public. Mr. George F. Sutton, solicitor, defended. Police-constable Hunt, 262, said at 4 p.m. on the 22nd ult. the defendant drove at a pace of 14 miles an hour into Holborn Circus going east. He gave no alarm of his approach, and continued at the same pace across the foot-crossing, colliding with a gentleman, and knocking him off his feet. The gentleman fell on the car, which was of low construction, was carried some yards on it, and then the defendant stopped. George Walter Thompson, pawnbroker and jeweller, an elderly man, corroborated the constable, and said he was the person collided with. The car came at a fierce pace, and was down on him before he had a chance of getting out of the way. He jumped or fell on the car. Cross-examined: So far as he knew at present he was not permanently injured. He could not write the same night, as his fingers were so swelled. Mr. Sutton said the defendant was the engineer to the Great Horseless Carriage Company, of 47, Holborn Viaduct, and a very expert driver. This was a motor-tricycle he was driving, and was only geared up to 10 miles an hour, but it was out of gear at the time, as it was simply running downhill by its own force. He thoroughly understood the machinery, and had driven the Duke of York. Had Mr. Thompson not stood hesitating in the road he would not have been touched. Sir Joseph Savory: You know the summons is under the City Police Act, 1839? Mr. Sutton: No; I thought it was under the Light Locomotives Act. Sir Joseph (after references to the Acts) said the defendant was clearly guilty under both. "Expert drivers" were sometimes liable to show off their skill by driving in a reckless manner. He imposed a fine of 10*s.* and costs.

LES POIDS LOURDS.

Report of the Commission—II.

After stating these general considerations the Commission proceeded to study each vehicle in particular. As these vehicles have already been described in our columns (*see* Automotor, Nos. 11 and 12, vol. 1), we need now only briefly recapitulate the leading features of each, commencing with the "Scotte" Omnibus, officially known as No. 1. It is constructed to carry 12 passengers and their luggage. The speed is stated at 8·7 miles per hour on a good level road, and 4 miles per hour on steep gradients.

Dimensions and Weight.

Weight empty, 9,240 lbs. = 4·125 tons.
„ on fore axle, 5,082 lbs.
„ on rear axle, 4,158 „
„ of water, 1,540 „
„ of coke, 220 „
„ of two men, 308 „
„ of tools, &c., 242 „
„ of cargo, 2,640 „
Total weight in working order, 14,190 lbs. = 6·335 tons.
Of this total weight the wagon weighs 65·1 per cent.
„ „ cargo weighs 18·6 „
„ „ fuel, stores, &c., weigh 15·6 per cent.
Fore wheels, 30·3 inches diameter.
Rear „ 35·4 „ „
Wheel base, 9·348 feet.
Length of wagon, 17·11 feet.
Breadth „ 5·576 „
Boiler (empty), 880 lbs.
Contained water, 110 lbs.
Steam pressure, 171 lbs. per square inch.
Grate area, 1·39 square feet.
Heating surface (not stated).

Weight of motor, 594 lbs.
Two simple engines, 4·3 inches by 4·5 inches.
Revs. per minute, 400.
I.H.P., 14.
Consumpt of coke per square foot of H.S., 67·4 lbs., nearly.
" water per lb. of coke, 5·3 lbs.
Commercial speed, 6·3 to 6·6 miles per hour.
Weight of coke burnt per ton-mile of total weight, 2·16 lbs.
" " " cargo, 11 lbs.
Total weight per I.H.P. = ·4525 ton.
The daily expenses are as follows:—

Price of omnibus, 22,000 francs.

	frs.	cents.
Interest at 6 per cent.	4	40
Repayment of capital, maintenance, and repairs (15 per cent.)	11	0
Driver at 200 francs a month	8	0
Stoker at 75 francs a month	3	0
Firing	1	10
Lubrication	1	70
Total	29	20
General expenses, 10 per cent.	2	92
Daily fixed expenses	32	12

The estimate of the kilometric working cost for a daily journey of 110 kilometres is based upon the following expenses:—

——	⅓ load.	⅔ load.	Full load.
Kilometric tons	577	621	665
Coke consumed—			
Weight .. kilogr.	358	385	412
Cost .. fr.	12·53	13·47	14·42
Water consumed—			
Volume .. litres.	1,968	2,118	2,268
Cost .. fr.	3·94	4·24	4·54
Daily expenses—			
Coke and water .. fr	16·47	17·71	18·96
Fixed expenses .. fr.	32·12	32·12	32 12
Totals .. fr.	48·59	49·83	51·08
Effective kilometric tons	44	88	132
Working cost—			
Passenger kilometre, with luggage or 100 kilos. of merchandise fr.	0·110	0·057	0·039
Passenger kilometre, without luggage .. fr.	0·079	0·040	0·028

The De Dion et Bouton Omnibus.

Official No. 14.

This omnibus is built for 16 passengers—12 inside and 4 on the platform. The speed that may be obtained is 12·4 miles per hour on the level and 6·7 miles on steep gradients. Its price is 22,000 francs, the same as that of the Scotte. The useful weight or cargo that can be carried is 3,250 lbs., but on the trials only 2,464 lbs. were carried.

Weight of wagon empty, 9,438 lbs. = 4·213 tons.
" water carried, 990 "
" coke " 264 "
" 2 men " 308 "
" tools, stores, &c., 88 "
" cargo carried, 2,464 "
Total weight, 13,552 lbs. = 6·05 tons.
Weight on fore axle, 4,312 lbs.
" rear " 9,240 "
Of total weight, wagon is 69·6 per cent.
" " cargo is 18·2 "
" " fuel, stores, &c., 12·2 per cent.
Length of wagon, 20·8 feet.
Breadth " 6·56 "
Diameter of fore wheel, 31·49 inches.
" rear " 39·37 "

Boiler, weight, empty, 1,056 lbs.
Steam pressure, 199 lbs. per square inch.
Grate area, 1·9 square feet.
Heating surface, 60 square feet.
Motor weight (not stated).
Revs. per minute, 600.
I.H.P., 25.
Consumpt.—Water evaporated per lb. of coke, 3·1 lbs.
" Coke burnt per square foot of H.S., 30·7 lbs.
Total weight per I.H.P. = ·242 ton.
The commercial speed is 8·4 to 8·7 miles per hour.

The consumpt of coke per ton-mile of the average total weight was 1·1 lbs., and of water 6·14 lbs., while the consumpt of coke per ton-mile of cargo was 6·13 lbs., and of water 38·06 lbs. The fixed daily expenses are as under:—

Price of vehicle, 22,000 francs.

	frs.	cents.
Interest at 6 per cent.	4	40
Repayment of capital, maintenance, and repairs (15 per cent.)	11	0
Driver	8	0
Stoker	3	0
Firing	1	42
Lubrication	5	90
Total	33	72
General expenses, 10 per cent.	3	37
Fixed daily expenses	37	09

The Panhard and Levassor Omnibus.

Official No. 10.

This omnibus has been constructed for passenger and light parcel service. It has accommodation for 14 passengers, the baggage being carried on the roof. The speed attained on the level is from 9·9 to 11·1 miles per hour, but this drops as low as 2·5 miles per hour on stiff gradients. The cost of the vehicle is 18,000 francs.

The following table gives the particulars of the distribution of the weight, &c.:—

Weight empty, 4,618 lbs.
" 1 conductor, 160 "
" water, 441 "
" *petrol, 71 "
" cargo, &c., 2,210 "
Total weight, 7,500 lbs. = 3·35 tons.
" on fore wheels (drivers), 2,425 lbs.
" on rear " 5,070 lbs.
Of total weight the wagon is .. 61·7 per cent.
" " cargo is .. 29·5 "
" " fuel, stores, crew, &c., is 8·8 "
100·0 "

Weight per H.P., $\frac{3 \cdot 35}{12}$ = ·28 ton nearly.

Length over all, 14·76 feet.
Breadth, 6·89 "
Height, 9·80 "

Of this length 4 feet are occupied by the machinery space, leaving 7·75 feet for passengers and cargo, and 2·95 feet for the rear platform.

Motor.—This is of the Daimler-Phœnix type, using light oil and incandescent ignition tubes. Its power is 12 H.P. Revs. per minute, 750.

There are four cylinders placed vertically two and two, thus giving two impulses or turning moments on the shaft at each revolution. The diameter of the cylinders is 3·537 inches, and stroke 5·3 inches.

When running at less than full load the speed of the motor would increase, and to avoid this a regulator is employed, whose action is as follows:—In these motors the exhaust valve is operated by a cam on a counter-shaft which makes two revolutions to each one of the crank-shaft, and the inlet valve is operated by the vacuum produced after the "scavenger" stroke. The action between the exhaust

* 50 litres, or 11 gallons at ·700 sp. gr.

valve and the cam on the counter-shaft is effected by a rod which is in two parts, and adjusting these the exhaust is delayed, either in one or all cylinders; in other words, the burnt gases are cushioned to any desired extent.

The consumption of petrol at ordinary speeds is 1·56 pints per mile, and of water 7·1 pints. The quantity of each that can be carried suffices for a run of about 62 miles. The commercial speed was found to be from 6¼ to 6½ miles per hour. The consumption of petrol per ton-mile of the average total weight was ·417 pint; and per ton-mile of cargo it was 1·4 pints; the consumption of water per pint of petrol was 5 pints.

The following is a statement of the fixed daily expenses:—

Price of omnibus, 18,000 francs.

	frs.	cents.
Interest at 6 per cent.	3	60
Repayment of capital, maintenance, and repairs (15 per cent.)	9	0
Driver	8	0
Lubrication, &c...	3	50
Total....	24	10
General expenses (10 per cent)	2	41
Fixed daily expenses	26	51

In order to arrive at the exact cost of working, and also to enable an accurate comparison to be made between the various vehicles the following tables have been prepared:—

Data for Ascertaining Working Cost.

PAPERS ON AUTOMOBILISM.

IN the Engineering Lecture Room of the Yorkshire College on December 13th, Mr. J. Sidney Critchley, M.I. Mech. E. (Coventry), gave an address on "The Daimler Motor and its Application to Autocars." Mr. J. H. Wicksteed (the President) occupied the chair, and there was a good attendance. The lecturer said the Daimler motor was the invention of Gottleib Daimler, who was at one time associated with Dr. Otto in his researches in connection with the gas-engine. The present revival of automotors was the outcome of experiments made 10 years ago. He gave a description of the different classes of motors—steam, oil, and electric—now in use, and contended that for all practical purposes the oil-motor was the most satisfactory, and that of the various types the Daimler occupied the foremost position, and was the best. It was a light oil-motor. Its special features were absence of smell, absence of vibration when on the road, and length of distance which the car could run without re-charging. A number of lantern slides were shown, one of which was of a Daimler motor-car which had been driven from John o'Groat's to Land's End. It carried two persons and 400 lbs. of luggage at an average speed of 10 miles an hour, and successfully surmounted all hills. In addition to exhibiting slides of various types of English-made carriages, Mr. Critchley illustrated types of several French cars—steam, petroleum, and electric, and he also gave views of carriages made by Hancock, Gurney, and others which were in use before the introduction of railways. The motor-car industry was only 12 months old in this country, but, in his opinion, motor-cars had come to stay.

ON December 31st, under the auspices of the Helsby Literary and Scientific Society, Mr. E. Shrapnell Smith, honorary organising secretary of the Self-Propelled Traffic Association (Liverpool Branch), gave a lecture on "Automobilism." The lecture was illustrated by lime-light slides, and was extremely interesting. It was divided under three main headings, viz., "Past," "Present," and "Future." The first section comprised a *résumé* of the past history of motor-cars, dating back to a time even in advance of the Victorian era. The lecturer dealt in an amusing style with the futile efforts of the Hon. Evelyn Ellis to secure a summons in order to bring on a test case. After speaking in a general manner on the advantages and disadvantages of oil and steam motors for self-propelled traffic, he enlarged at some length on the simplicity and undoubted future before electricity as a means of road locomotion, especially the freedom from vibration ensured by its use, as well as the self-starting advantages. In treating of electrical vehicles, he referred in detail to the *modus operandi* of the London Electrical Cab Company with reference to the recharging of the cells. Some humorous slides representing possible scenes in the streets of a large town some years hence, when the advent of the motor-car has been more thoroughly established, concluded the lecture, which resulted in a vote of thanks being passed to the lecturer for a thoroughly enjoyable evening.

THE LIQUID FUEL COMPANY'S AUTOMOBILE TRAIN.

In our last issue we described this train, which has been built by the Liquid Fuel Engineering Company, of Cowes, to run between Cirencester and Fairford, in connection with the Midland and South-Western Junction Railway. We now give an illustration showing the train. As will be seen, it consists of a motor-tractor carrying goods, &c., and a passenger car. This novel conveyance is much appreciated in the district, and forms a much-needed and valuable object lesson.

We understand that amongst other orders the Liquid Fuel Engineering Company have just secured a contract to build two of their vans for Messrs. Spiers and Pond, and as demonstrating the practical value of the Company's steam-vans it is worth noting that the van portion of the above train has been running at Swindon for some weeks during Christmas time for suburban deliveries on behalf of the railway company, delivering an average of 5 tons each morning before midday without a single hitch. The railway company, for whom this work has been done, estimate that it would have been impossible to have done the same amount of work with two pair-horse vans. An ounce of facts of this description is worth a hundred pounds of theory as to the future of the motor-car.

The Motor-Car Emporium (Limited).— Under this title a Company was recently formed for the purpose of constructing, importing, and dealing generally in motors and motor-cars, this Company being the sole agents for several of the leading Continental manufacturers, including Emile Mors, Paris; Compagnie Générale des Automobiles, Paris; Compagnie des Moteurs et Automobiles, M.L.B., Paris; Établissement Hurtu, Paris; Henri Vallée, of Le Mans; and Th. Cambier and Co., of Lille. We understand that the Company are already able to show some specimen carriages, and are prepared to execute orders with practically no delay; and they claim that amongst several useful inventions of which they have the sole monopoly is a patent apparatus of MM. les Fils de A. Deutch, of Paris, for the purpose of getting rid of the unpleasant smell resulting from the imperfect combustion in oil-motors. The managing director is Mr. Charles Heyermans, 10, Clanricarde Gardens, W.

THE HEAT OF COMBUSTION OF ACETYLENE.

Engineers quite commonly estimate the calorific value of a fuel from its chemical composition; and, speaking generally, the figures thus obtained are accurate within quite a small percentage. Exceptions, however, do occur, and acetylene is one of them. Its chemical composition is given by the formula $C_2 H_2$, so that 13 lbs. of the gas consist of 12 lbs. of carbon and 1 lb. of hydrogen. Now, 12 lbs. of carbon burnt to carbonic acid gas will give 174,600 British thermal units, and 1 lb. of hydrogen, burnt to H_2O, will liberate 61,560 British thermal units, making a total of 236,160 units. Actual experiment, however, shows the heat set free on the complete combustion of acetylene to be much greater, viz., 281,250 heat units, or nearly one-fifth more than that calculated from its chemical composition. Similarly, it is found that the actual heat of combustion of cyanogen ($C_2 N_2$) is nearly one-third more than that calculated from its carbon content. The explanation of the discrepancy is, of course, to be found in the fact that a large quantity of energy is absorbed in the production of these compounds, which is liberated in the form of heat on burning them. It is this fact, says *Engineering*, which renders compressed acetylene so dangerous an explosive, as, quite apart from any question of combustion, there is a large store of energy available for destructive purposes by the mere decomposition of the body into its elements. Some French experiments, indeed, showed the explosive energy of liquefied acetylene to be comparable to that of dynamite. It should, however, at the same time be stated that at pressures not exceeding two atmospheres it was found impossible to produce an explosive decomposition of the gas which, under such conditions, is as safe as lighting gas. It is interesting to note that many food stuffs, such as starch and sugar, exhibit the same peculiarity as acetylene, their heat of combustion being greater than that estimated from their chemical composition.

Automobile Journals.— The not inconsiderable number of journals devoted to automobilism in its various phases is already large, but has been again added to by the appearance of a new paper called *La Cote financière de L'Automobile et du Cycle.* As its name implies, it deals with the financial aspect of automobile companies, and if it does this with independence and with clean hands it will be in the position to render good service to the French public.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents :—*

London : POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale : BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.

Birmingham : J. MCCANN, 37, Union Street.

Manchester : JOHN HEYWOOD, Deansgate.

Newcastle-on-Tyne : C. C. ROSS, 35, Side.

Paris : HOMÈRE MOREAU, 97, Rue Nollet.

Victoria (Australia) : PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Most of the back numbers can still be obtained at 6d. per copy, or 7d. per copy post free.

INDEX TO VOL. I

Is Published Free with the October Number.

NOTICE.—The price of Volume I, bound complete, was first raised to One Guinea net, and then Two Guineas, and is now entirely out of print.

COVERS FOR BINDING VOLUME I

OF THE

AUTOMOTOR & HORSELESS VEHICLE JOURNAL

Price 1s. 6d.; Post Free, 1s. 9d.

Can be obtained through the usual Agents, or direct from the Publishers.

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

JANUARY 15TH, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

[*For full programme and proceedings of the Self-Propelled Traffic Association, see p. 105.*]

1898.	
Jan. 20-29 ..	Midland Cycle and Motor-Car Exhibition, Bingley Hall, Birmingham.
Feb. 3-12 ..	Sheffield Cycle, Motor-Car, and Accessories Exhibition, Drill Hall, Sheffield.
Feb. 14 ..	Yorkshire College Engineering Society—"The Steam Turbine Engine and its Applications," by John D. Bailie (C. A. Parsons and Co., Newcastle).
March 6 and 7	Marseilles and Nice Race (organised by *La France Automobile*).
May 2, 9, 16, 23	Society of Arts Cantor Lectures—"Electric Traction," by Prof Carus Wilson.
May 24 ..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
June	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
	Concours of the Automobile Club Belge.
July 5.. ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

RUSTICUS.—We have forwarded your letter to a respectable firm of patent agents, who will doubtless communicate with you.

CHICHESTER.—The address is Whitehall Court, London, W.C.

ELECTRIC.—Your information was quite correct, but although all arrangements were made, the van did not start on Monday last.

J. LEDGER (Dunstable).—The vehicle you require could be obtained from the Daimler Motor Company, 219, Shaftesbury Avenue, W.C.

REVERSING (Manchester).—(*a*) No. Decidedly not. What you suggest is practically impossible (*b*) You will find the fullest details in our AUTOMOTOR POCKET-BOOK for 1898.

GERMANICUS.—The agency has only just been taken up for this engine in England. If space permits we are giving a full description in the current issue, but failing this, it will be in our next.

No. 1 (Liverpool).—Volume I is entirely out of print. Although we raised the price, first to one guinea and afterwards to two guineas, every copy has gone. We can still send you all the back numbers at 7*d.* per copy, with the exception of No. 1. Thanks for good wishes.

INVESTOR.—It is impossible for us to repeat the figures and particulars you ask. Refer to our index to Vol. I, published in our October number, and all references both to the Syndicate and kindred matters can easily be traced.

P. F. (Dundee).—Our 1898 POCKET-BOOK was published just at the end of last year. We feel sure you will find in it all you require, and we should advise you seeing Messrs. Julius Harvey and Co., Consulting Engineers, of 11, Queen Victoria Street, E.C., upon the matter.

HIGH OR LOW TEST PETROLEUM.

As our readers are aware, for some years past an agitation against the use of low-test petroleum burning oil for domestic purposes has been carried on by various newspapers and persons who, under the guise of protecting public interests, really pander to popular ignorance and popular prejudice. This agitation has derived much of its force from the fact that the supply of burning oil to this country has virtually been an American monopoly. The burning oil so supplied complies with our Petroleum Acts and "flashes" between 73° and 78° about. That a vast number of deaths and much family distress have accompanied the use of this oil is only too true, and hence the uninformed, non-technical, but very hysterical writers in the daily Press have got in the habit of speaking of ordinary burning oil as the "deadly 73°." Now in those cases of death or maiming where a careful examination of the exploded lamp is made, it is invariably found to be the case that the lamp was of improper construction, that it was dirty, that it was not properly trimmed, and, lastly, that the user was crassly ignorant of the means to be taken, not only to ensure a good light but also safety. We have, in short, a cheap and wholly improper lamp in which is burnt a cheap oil, and the thing is used by the least educated classes of the community, with the natural result that fires and explosions occur with alarming frequency. To say, however, that this state of things can be remedied by raising the flash point is inaccurate. Perhaps the best and most effective means of avoiding these disasters would be to give practical instruction in the Board Schools on the use of petroleum and lamps. The writer proposed this a few years ago to the London School Board, but that body was too busy over the more vital and soul-absorbing question of religious teaching. However, Parliament has been asked to raise the flash point to 100° F., and since 1894 a Select Committee has been sitting at intervals, but so far has not yet reported, and we should not be surprised to learn that their finding will be to the effect that the commercial disadvantages attending a high-flash point are far greater than the risk attaching to the use of low-flash oil. While we quite admit that oil of 100° F. is safer than oil of 73° F., yet to render the use of the former compulsory by legislative enactment is a drastic measure only justified by the most urgent necessity. We must recollect that in tens of thousands of families the so-called "deadly 73°" is used with perfect safety simply because common sense obtains in most households.

The experience of the whole community is to the effect that this so-called "deadly 73°," if burnt in good lamps, is a perfectly safe illuminant. If while raising the flash point to 100° F. steps were also taken to ensure the employment of reasonably safe lamps, then the object ostensibly aimed at, viz., the safety of the workers' lives, would be achieved, but raising the flash point to 100° F. and then burning the oil in defective and improperly-made lamps is like putting new wine in old bottles. Besides, the small increase in the proposed flash point would not greatly promote safety. If danger lies in the use of low-test oil in bad lamps, will this be much, if at all, lessened by raising the test by the small amount of 27° and burning the oil in the same description of lamp? On the other hand, raising the test means increasing the price. The public, or rather that section of it that gets burnt, will always buy the cheapest article irrespective of quality, and if it be logical and praiseworthy to prevent them buying low-test oil, is it not equally so to prevent them buying cheap and defective lamps? In this question we must carefully avoid the claptrapand drivel with which it has been surrounded by such papers as the *Daily Chronicle*, *Star*, *London*, and others after that kind. We shall, of course, be told that we are defending low-test oil for any but righteous motives. As a matter of fact, we defend the low test because this oil is extensively used in oil motors. This oil is easily volatilised and converted into gas, and the higher the test the higher the temperature at which the oil is gasified. If we have a legal high test it will mean the abandonment of a reasonably safe oil (low test) and using the still more dangerous lower flashing hydro-carbons. And the automobilist and the store dealer must ask, Is it safer to keep a store of 73° petroleum or of spirit which flashes at ordinary temperatures? All things considered, we say no sufficient case has been made out for raising the legal limit. Really, however, all the hysteria indulged in by the uninstructed daily papers of a certain political complexion springs, not so much from any desire to benefit the working classes as from a wish to break down the practical monopoly of the sale of petroleum enjoyed by the Anglo-American Oil Company. We quite sympathise with this up to a certain point. The Anglo-American, or rather its parent, the Standard, controls the oil production of the United States. The other great oil field is in South-East Russia, and is controlled by the Rothschilds and Nobels. Similar oil to the Russian is obtained in Galicia. These two oil-producing centres practically supply the world. We are now told that the American monopoly is about to be broken down, by the placing upon the English market of a "Water White" Russian oil, flashing at 103° F., by another group of monopolists, headed by the Rothschilds. We are not greatly concerned in the matter, any further than if it means a reduction in price we shall welcome the competition; and if this high-test Russian oil can compete with the American low-test oil so much the better. It is, however, worth while to point out that the heavy Russian oil does not burn so well in common lamps as the lighter American. We, of course, welcome every improvement in manufacture which enables a better article to be supplied at a lower price, and so are quite content to see Rothschild and Rockfeller fight for the English market. What, however, we protest against, in the interest of automobilism, is the placing of any further legal restrictions upon the sale and storage of petroleum, and hence we are in favour of the low-test limit being maintained.

G. H. L.

PERSONAL.

It is gratifying to us to note the very widespread manner in which our Journal is being quoted in regard to various matters connected with motor-vehicles, a special instance being an item of news which we exclusively published in our issue of December 15th last, announcing the inauguration of steam motor Post Office parcel vans, known as the "Lifu," by the Post Office authorities. Amongst a very large number of leading newspapers that gave due prominence to our exclusive information, we are pleased to note the following:—The *Times*, *Engineer*, *Financial Times*, *Daily Mail*, *Evening News*, *Star*, *Daily Graphic*, *Sun*, *Liverpool Journal of Commerce*, *Birmingham Daily Post*, *Leicester Mercury*, *Electrical Review*, *Rialto*, *Engineer and Iron Trades' Advertiser*, *Local Government Journal*, *Railway Times*, *Civil Service Gazette*, &c. In most instances, as befits high-class journalism, full credit was given to us for the information, but we are sorry to note some exceptions, viz., the *Daily Telegraph* and *Daily News*. Considering the reputation these papers are credited with we must confess we were somewhat surprised. They certainly did not use the information on the day of publication, but rightly or wrongly no doubt took the trouble to check its accuracy before making any announcement upon such an important departure; but the paragraph which appeared in their issue of December 15th was followed on the 17th by a leading and also special descriptive article upon the same subject. We are happy to believe that this sudden interest in the matter was the result of the information with which our Journal had supplied them; but we certainly think that a slight acknowledgment of its source would have been not more than courtesy required, to say nothing of journalistic etiquette.

Who Makes the Post Office Motor-Vans?

Referring to this Post Office departure, a "G. H. Shareholder" writing to the *Financial Times* asks "whether the successful motor-van being used by the General Post Office was built by any of the Lawson group of companies, or is in any way covered by any of the 'master patents' of which we have heard so much."

The latter part of the following reply from the B.M.S. Secretary is sublime in its condescension and assumed superiority:—

To the Editor of the Financial Times.

Sir,—Replying to the letter in to-day's issue respecting the use of motor-vehicles by the Post Office, I should like to say that the department has been using and testing our vans for some time past. The vans have punctually done duty day after day, calling at the various offices to a fixed time-table, receiving Her Majesty's mails, and punctually discharging the same. Several routes were tried with complete success. We carried 12 cwt., but beyond this size we have nothing in stock at present. The Post Office authorities expressed their extreme satisfaction at the splendid manner in which our motor-vans performed their duties. As a result, we are now building three larger and more powerful vans to especially meet the requirements of the Post Office night work and heavy loads. The expense of working was only fractional to the expense of horse-drawn vans. We understand a steam van, in which petroleum is burnt as fuel to heat the boiler to generate the steam necessary to drive the engine, is also being tested, together with other systems. We use a few drips of petrol spirit and a few pints of atmospheric air at every stroke to move the engine, which is exceedingly clean, and works so perfectly that smoke, sulphur, and other offensive fumes are entirely absent in working. Our little petrol engines are being proved "master patents," but we do not claim the use of petroleum as fuel, and without wishing to discourage experiment in that direction, we think, from the result of our own experiments, that the intolerable fumes of petroleum when it is being burnt as fuel would make it quite insufferable for ordinary street traffic. No doubt for traction-engine purposes along a country road it might be used with a fair amount of success.—I am, &c., Charles Jarrott, Secretary.

The British Motor Company (Limited),
40, Holborn Viaduct, E.C., *December 21st*, 1897.

THE DAILY PRESS AGAIN.

The daily Press professes to advise and instruct the public on everything—especially motors. With absolutely no technical knowledge or experience the scribes in Fleet Street will criticise a yacht or an armour plate rolling mill. These are the ignorant people who inform their readers that a new battleship designed by the ablest men in the country is "50 feet too short" or too long, or too anything. Naturally the performances of the Heilmann Locomotive, which we shall describe next month, came under this critical survey, and many and curious are the opinions that have been expressed. Thus the *Daily Chronicle* labours under the idea that the Heilmann locomotive can hardly pay because it is worked by accumulators! It were charitable to assume that the writer of this precious "opinion" made a mistake, as we are all prone to do, but this is to expose his crass ignorance, because no one with any knowledge of accumulators or locomotives could for a moment make such a blunder. We then have the *Daily News*—a paper of literary reputation—publishing a leading article on the "Transmutation of Metals," and inferentially asking its readers to believe that, thanks to the discoveries of an American "scientist," silver can be transformed into gold. Of course the *Daily News* has been badly "had"; but really in this age of education is it too much to ask that newspapers of standing and reputation should refrain from publishing as sober, solid information matter which any fairly well educated boy would at once classify as "rot"? We should not allude to the shortcomings of our daily contemporaries were it not that many of them in their capacities as "leaders of thought," "framers of public opinion," and "voices of the masses" publish such erroneous statements concerning automobilism. Thus in our last month's issue we showed how deplorable was the ignorance of a leader-writer of the *Daily Telegraph* on the turning powers of automotor vehicles. We therefore feel it incumbent upon us to show by actual example that the opinion of the daily Press on technical matters is, to put it mildly, utterly unreliable. So long as they report facts as they observe them, the lay Press is always interesting, if not instructive. On politics, religion, art, and such like matters which do not admit of scientific solution and which require no special knowledge in order to express an opinion or criticism, the daily Press is also interesting if not useful. When, however, it expresses opinions on material things which are directly subject to physical laws, then it is neither interesting, instructive, nor useful, and it justly incurs animadversion.

IMPORTANT CORRECTION.

We regret to have to make a rather important correction in our Pocket-Book, and one which we discovered ourselves and are not indebted to (as is usually the case) any of our readers.

On p. 79 we give a formula for determining the horse-power required to propel a vehicle on an incline. This should read—

$$\text{H.P.} = \frac{(\text{R. Cos } a \pm 2240 \text{ Sin } a)\ \text{W.V.}}{375}$$

In the Pocket-Book the expression Sin a has been omitted.

The Liverpool Heavy Weight Competition.—We trust that manufacturers are going to show our Continental friends that the hand of the British designer has not lost its cunning, and that in spite of the restrictive—and we think needlessly so—clauses as to weights that, if not the proverbial coach and four, a heavy motor-wagon can be, as we think it can, driven through the Locomotives on Highways Act. The successful builder of such a vehicle will not, we can assure him, find his work unappreciated. On the contrary, he will have his hands full of orders for the next few years. Apart from the advertisement to be derived from gaining a prize from the S.P.T.A. there is thus a distinctly solid inducement held out. One well-known Liverpool shipowner, largely interested in cartage, has publicly announced his intention to place an order for 50 wagons directly the first one is passed by the judges. The large carriers of London are closely watching developments and, as we are assured by one of them, they will discard horses on the first opportunity. We may say from our own knowledge that French and German firms are competing, and it will be a thousand pities if the prize has to go to an alien.

LINDSAY'S COIL CLUTCH.

With the extension of automobilism and the use of oil-motors for vehicles, the demand for a really good clutch is not likely to flag. In the majority of automotor vehicles the weak point is usually the speed-changing gear, and this, sooner or later, gives trouble because the motion is either arrested or imparted suddenly. A clutch which acts not only as a means of transmitting power, but which permits

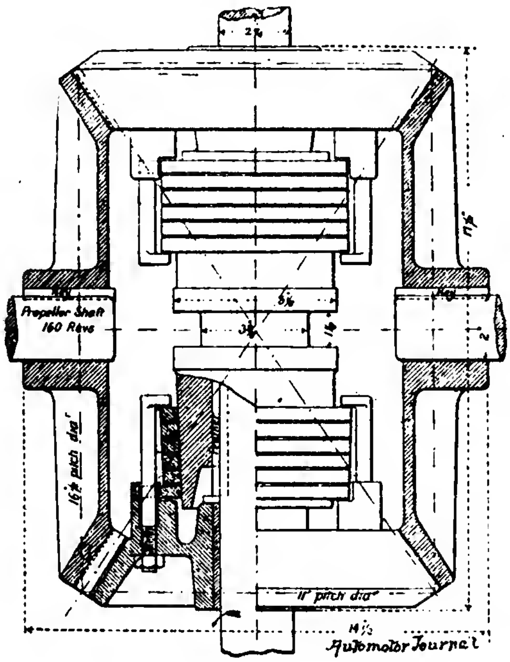

Fig. 1.

this to be transmitted in either direction or varied, as regards speed, without the slightest shock or noise, and which also acts as a most efficient brake, finds its proper rôle in automotor vehicles. Such a clutch is Lindsay's Coil Clutch, which we illustrate in the accompanying drawing. The principle of this transmitting device is very simple. One of the cheapest and most efficient brakes is that employed by winchmen on board ship, and also by most French makers of automotor vehicles. A rope, either of hemp or wire, is made fast at one end, and a few turns taken round the rotating axle or shaft, and the free end lightly pulled; frictional resistance tightens up the rope, and so close is the grip that the motion is quickly arrested, but not instantaneously. Really, such a device is an absorption dynamometer. By employing a rope sufficiently strong, and using enough turns, the motion of shafts of the largest sizes can be more effectually arrested than by any other means. In applying this principle various modifications, in which the coil is applied, may be employed. But the Coil Clutch and Pulley Company, of Slough, the manufacturers of Lindsay's patent, make two types. In the one, a coil of steel, of square section, is attached to the pulley or pinion to be driven; on the driving-shaft is a steel-covered sleeve which is keyed to and revolves with the latter. By means of a sliding clutch the other end (the free end) is made to engage the sleeve; the result is that the whole coil grips the sleeve with an intense and uniform force all round its periphery, and the motion of the driving-shaft is communicated or, conversely, by releasing the grip the motion of the driven shaft or pulley is arrested. In the illustration we show how this coil clutch is applied to launches worked by uni-direction oil-engines. It will be seen that the coned clutches are connected to the wheels, and the sliding sleeve is inserted by means of a lever into that one it is desired to drive.

Another form of coil clutch is shown in Fig 2. This clutch consists of a chilled sleeve keyed to the shaft, around which chill a steel coil, of diminishing section, is wound, and by means of a bell-crank lever, actuated by a sliding plate, the coil is tightened on the sleeve and, coil friction being set up, the clutch commences to drive.

This clutch is lighter and takes up less room than the other type (of equal power), and has the advantages of starting and stopping instantly. It can, if desirable, be put slowly into gear so as to pick up the heaviest of drives without shock, and yet be released in an instant.

It is quite shockless in its action, and particularly suitable for heavy drives, such as the heaviest kind of motor vehicles; for the lighter vehicles we should recommend a modification of Fig. 1. These clutches have been extensively used in tramcar propulsion, indeed, it is only by their use that gas and oil engines can be used for this work.

The coils are forged from gradually tapering steel bars, and are wound into helices. The varying section supplies the strength at the part where it is needed, and renders the coil more elastic and delicate in action. So sensitive is it that a very small boy can, and does, manage a rolling mill, reversing it several times a minute, and without putting more than the minutest amount of end friction on the clutch disc. Immediately the pressure is released from a coil it liberates itself with absolute certainty, while the moment it is pressed it takes up its work without noise or shock. The clutch bosses, or sleeves, are of deeply chilled cast iron, ground to a fine surface. Naturally there is an enormous pressure on them, and it is for this reason that they are made as hard as possible. As an evidence of the extreme delicacy of coil clutches, we may mention that the same coil will act both as clutch and a brake. For instance, if such a clutch be fitted to a winding drum or hoist, the load may be held stationary in mid-air without stopping the engine, the friction between the coil and the sleeve being so readily graduated that the road neither runs up nor down. If the hoist is to be driven both ways by power, then a double-acting coil is fitted, consisting of a coil with a central head and with right and left-handed convolutions on either side, and the load may be held either in ascending or descending.

These clutches seem to us to meet a very practical problem in motor-vehicle design, as they not only act as transmitting clutches but, by the means shown in the illustration, they enable the direction of the driven shaft to be so easily reversed or the motion stopped. Should any readers be interested in the matter, the Coil Clutch Company state that enquiries can be addressed to the following manufacturers of motor vehicles, who have used these clutches:—Messrs. Urquhart and Bolee, 57, Barton's Arcade, Manchester; Messrs. Roots and Venables, 100, Westminster Bridge Road, London; and the Clement Cycle Company, Paris.

The Motor-Car Company.—This Company has recently removed from their former premises in Red Lion Square, and has taken larger and more extensive premises at 93 and 94, Long Acre. They have a large stock of motor-carriages on show, among them being several very fine specimens of the carriage-builder's art. In particular they have a steam landau fitted with two pairs of vertical engines, thus dispensing with differential gear. Steam is supplied from a coil boiler, and the heat is obtained from a Bunsen burner of special construction. We hope to illustrate this fully in a future issue. At present the trials have not been completed.

REVIEWS OF BOOKS.

Whitaker's Mechanical Engineers' Pocket Book.—If there be one book more than another that is almost an essential to the man of affairs, it is "Whitaker's Almanack," which is *sui generis*, but as regards pocket books relating to the engineering profession there are not a few, and we do not think Messrs. Whitaker will find such a demand in the future for their new venture as they have experienced for their better known volume. Not but what the present work is in every way worth its money. It is edited and compiled by a well-known engineer—an authority in his own special branch—Mr. Phillip R. Bjorling, while the paper, printing, binding, and general get-up make it resemble an *edition de luxe* rather than a prosaic book of figures intended for office use. A Pocket Book for "Mechanical" (*sic*) Engineers is rather a large order, as the field of mechanical engineering is so vast that the data, &c., relating to many important branches cannot be gathered together in much less than ponderous tomes. At the same time Mr. Bjorling has performed his task well and ably, and really covers a lot of ground. He gives no less than 130 separate tables. In his arrangement, too, he is properly methodical, and all the subjects are classified. One thus has no difficulty in finding a thing, or if one has, a very copious and complete index can be consulted. It is much to be desired that the Institutions of Civil and Mechanical Engineers would arrive at a suitable nomenclature. Thus, one maker of pocket books calls a speed S, another V; with one a weight is W, with another it is P, or some other letter. Mr. Bjorling does not seem to have followed any of the leading writers on engineering in this respect, but has adopted the alphabetical system of writing his formulæ. We already have not a few ways of expressing the same thing, and this at times leads to confusion in drawing offices, where one man uses Molesworth, another Seaton, and another Mackrow; and the latter name reminds us that Mr. Bjorling has not included much information relating to marine engineering or naval science in his book. On those subjects with which Mr. Bjorling's name is honourably identified—pumps and water—the information is distinctly good and in many respects original, the data relating to hydraulics being especially so. Mining machinery is also well treated, and the same remark applies to gearing. On that particular branch of engineering with which we are more particularly concerned, viz., automobilism in its various forms, not much is said, but what is, is good. In conclusion, we can honestly recommend the work, which is not dear at the price—5*s*.

CATALOGUES.

PORTABLE RAILWAYS, or, as we should term them, light railways, are a subject occupying a good deal of attention just now at the hands of County Councils and others. Messrs. Bolling and Lowe's catalogue of their light railway plant affords a deal of very useful information which may be studied with advantage. They supply all kinds of railways, from the temporary line laid down to transport sugar or other produce, to the kind of line which would pass the Board of Trade. They also give prices to all the various parts, and this will greatly assist in getting the estimates, while the numerous illustrations give a large field for selection.

THE "TRUSTY" OIL-ENGINE is a well-known and highly appreciated motor; since its advent some years ago it has been from time to time improved, and at present is, perhaps, as perfect as an oil-engine operating on the Beau de Rochas cycle can be. In this last catalogue we notice that the makers have introduced some new types of portable engines which we should think would sell readily in country and colonial districts, or wherever a reliable motor was wanted and where petroleum could be obtained. A good point about these motors is that they consume common lamp oil and cost little or nothing in the shape of skilled attendance. The catalogue which the makers have sent us contains the records of tests, &c., made by various engineers. It is worth noting that the Trusty Oil-Engine can be easily converted into an ordinary gas-engine.

THE POST OFFICE MAIL VANS.

NOTHING can be more satisfactory than the performance of the "Lifu" mail vans under the Post Office arrangements. So far there has been no hitch or delay of any kind. On the contrary, as will be seen by Messrs. Julius Harvey and Co.'s letter elsewhere, the schedule times have been beaten repeatedly, and it has been abundantly demonstrated that much less time than is accorded to horse-drawn vehicles is required for the delivery of mails, &c., when efficient automobiles are employed. Messrs. Julius Harvey and the Liquid Fuel Company have achieved a distinct success; they have practically demonstrated the superiority in every way of the automotor, and its great advantages for postal service. It is a distinct triumph for mechanism over animal power. While congratulating the firms mentioned, we must also congratulate the Post Office officials on their quick appreciation and foresight. The above illustration shows the general appearance of the van.

Waiting for the Perfect Dust-Cart.—A short time ago the Vestry of Kensington instructed the Plant and Wharves Committee to report upon the employment of motor-carts for the collection of house refuse. In this connection the Committee, at a recent Vestry meeting, submitted the following report from the Vestry Surveyor:—"I have considered the question of motor-vans for the parish work, and am of opinion that steam or oil motors are unsuitable for the work of the Vestry, but that the adoption of electrically-propelled vans, as suggested in my report of March 12th, 1892, is highly desirable. The only question is whether the time is ripe for their adoption. Upon this point, after carefully considering the subject and all the details connected therewith, and after consulting the best authorities in the metropolis, I am of opinion that the subject should be deferred for the present. I may add that as I was the first municipal surveyor to suggest the employment of electric traction for the haulage of dust-carts, I will take care that this Vestry shall not be behindhand in the prudent adoption of such motors, but at the present time I am of opinion that it is not advisable to go in for same." In presenting this report the Plant and Wharves Committee expressed their concurrence in the opinion therein stated. We would like to know what technical knowledge of automobilism this Vestry Surveyor possesses, what degree or certificate of engineering he holds, and who are the "best authorities." We would suggest to the Kensington Vestry that they reconsider the matter, as on the face of it the advice is not, we think, justified by present practice.

NOTES OF THE MONTH.

HORSE cardrivers and conductors in Leeds are required to have an extra license before they are allowed to act as "motor" men.

HIS MAJESTY LEOPOLD, the King of the Belgians, has accorded his patronage to the Brussels Cycle and Automobile Show, on the committee of which are M. Le Baron de Zuylen and Sir David Salomons.

GENERAL BILLOT was much struck by the work done by the automobiles tested last autumn over a tract of country 120 miles in length, and he has ordered two carriages from M. Peugeot and MM. Panhard and Levassor.

THE motor-vehicle has made its appearance in Cape Town, Messrs. Koenig and Co. having imported what seems from the description in the *Cape Times* to be a Benz motor. It can carry eight persons, and has a range of speed varying from 1 to 16 miles.

WHO is responsible for disseminating the absurd canard to the effect that the Coachmakers' Company is offering prizes this year for the best designs of motor-vehicles? Quite a number of papers have been thus hoaxed. As a matter of fact, as we point out elsewhere, the Company assure us that they are not offering any prizes this year.

THIS is from the *Globe* :—From a journal of the distant future we cut, with a prophetic pair of scissors, the following paragraph :—"Some 29 inmates of the Home of Rest for Motor-Cars enjoyed their New Year's dinner on Saturday. Each motor-car received two gallons of best paraffin and a pint of machine oil. The oldest inhabitant of the home is Rattle-your-Bones, the only surviving car which took part in the famous initial run to Brighton in 1896."

AT a recent special meeting of the Hamilton Town Council an application by the Stirling Motor-Carriages (Limited) for a feu plot of the vacant ground on the town lands for this new industry was considered. It is proposed to plant the works on the same site as the gasworks. The Motor Company asked for three acres of ground, and the recommendation of the committee was to grant this at 3*s*. 6*d*. per pole. An amendment, however, was proposed fixing the amount at 2*s*. 6*d*. a pole, and this was eventually carried.

WHILE many municipalities and vestries are displaying a gratifying eagerness to obtain motor dust-carts—a progressive and liberal wish with which we strongly sympathise and encourage—Camberwell intends to use motor watering-carts, a most capital and economical idea. The water can thus be used for cooling and condensation at absolutely no cost. We observe that Mr. Daldorph intends to ask the Clerkenwell Vestry to instruct the clerk to ascertain the cost of purchasing and maintaining an electric water-van for street watering in the parish, and to report on the question to the Works Committee.

WITH the village carrier we are all familiar, but he, like all human institutions, is liable to change, and we are afraid that the horse and cart that used to jog comfortably between one town and another is likely to be replaced by the swift, rushing motor-van. Mr. Love, of Kirkaldy, N.B.—a daring iconoclast —has started a carrier's business with a motor-van, and is carrying parcels, goods, &c., in it with considerable success. From an account in the *Fifeshire Advertiser*, it would seem that Mr. Love has the nucleus of a big business in his hands. We wish him every success.

AT Partick, N.B., one of the local Councillors, Mr. Logan, speaking on offers for the proposed extension of the lighting department, said it had been suggested that they should do away with horses for the fire brigade and use motors. In that case the present stables could be utilised for the lighting department. The Provost said there was no particular reason why they should rush the matter, and he thought they should be very cautious about adopting motors for the brigade. They might break down at the most critical moment. Ultimately it was agreed to delay acceptance of the offers for a month. Perhaps some of our readers will enlighten the worthy Provost.

THIS is from a new paper called the *Sunday Special* :—"The world is badly in need of a genius who will invent a new form for motor-cars. The electric cabs on London streets are too much like growlers that have forgotten to bring along their shafts and horses, and the tricycle hansom, which the *Globe* bemoans has not found favour in English eyes, is too much like unto a bath-chair to meet with the approval of able-bodied beings. Some new form is wanted, something dainty, fragile-looking, tasteful, aristocratic, and airy, yet as unsinkable as a bell-buoy. Anything with the elegance of a gazelle and the gazelle's speed, but strong enough to crush a brewer's dray, will do."

ALL the horse tramcars have been taken off the streets of Buda-Pesth. The whole of the tramway lines have been converted into electric lines for a length of 70 English miles, while the Buda-Pesth Underground Railway also has electric traction for a further distance of 53 miles. This is not bad for a town of only 600,000 inhabitants; but the Hungarians are not yet satisfied, and plans for an extensive system of electric elevated and underground railways have just been made public, and received with general approval, like everything else tending to embellish or improve the thriving city. It is said that Buda-Pesth is the only large town in Europe in which the horse has been banished from the streets, so far as the trams are concerned.

ONE "J. G. S." writes from the New Club, Glasgow, to *The Engineer* thusly :—"Some time ago I noticed in your advertising columns notices of self-propelled carriages. I do not see any advertisements of this kind now. Are the makers of these carriages now so busy that they have no need of more orders, or is it that they have been unable to cope with such orders as they have received? Being desirous of obtaining a motor-carriage driven by electricity or other power, I find that after examining the advertising columns of the technical Press, and of bicycling and sporting papers, I am still unable to find any clue as to where I should address myself. I enclose my name and address, and should be very pleased if any of the makers should consider it worth their trouble to fulfil my wants."

"THERE must be many people," says the *Newcastle Chronicle*, "who sigh for the advent of the automotive car on humanitarian grounds. In the vicinity of Elswick the other day (writes a correspondent) a pony attached to a heavily-laden cart was being thrashed unmercifully up a very steep bank by its driver. The poor animal, judging by its projecting bones and meagre appearance, seemed half starved; the load being sufficient for a well-fed horse, the excessive strain upon the pony can be more easily imagined than described. The ordinary whip in this instance proved inadequate; therefore the driver belaboured the exhausted pony with a heavy cudgel, forcing it, against its limited strength, to the top. This kind of ill-treatment is unfortunately very common with boys leading coals and other household requisites, but something better is looked for from those who have arrived at years of discretion. There is, however, some consolation in the reflection that in the near future these cruelties will terminate with the installation of motor traffic."

ALTHOUGH Coventry is supposed to be *a* home, if not *the* home of the motor industry, the local Solons have hardly appreciated the fact. We read that at a recent meeting of the Town Council Councillor Johnson called attention to the possibility of using motor-power for Corporation dust-carts, as was done at Chiswick. The saving he estimated at £1,000 a year. Councillor Lee had a few words on the same subject, and it appeared from an extract read by Alderman Marriott from the city engineer's report on the reorganisation of his department, that in his estimate he had uot considered the possibility of using motor instead of horse power, but if such a thing were possible it would save a large expense on horse keep. Just conceive, if you can, the abysmal ignorance of a person who says *if it were possible* to employ a motor dust-cart, &c. Had the proposal been to employ balloon cycles a doubt might well have been expressed, but after Chiswick there can be no question of possibillty.

UNDER legal intelligence we report a case in commenting upon which the *Globe* says :—"A policeman on duty in Holborn Circus on Thursday had a rather novel experience; for he saw an old gentleman who was crossing the road suddenly caught up and whirled away by a motor-car, which was travelling at the rate of 14 miles an hour. The case suggests possibilities for the future. When the horse disappears from our street traffic, we may thus be able to put an end to street accidents. A modification of the railway cow-catcher in front of each car will either tenderly lift up the careless pedestrian or shovel him gently aside. Perhaps inventive science will even produce a kind of man-catcher, which would receive the foot-passenger in a funnel-shaped net in front, conduct him through a flue under the body of the carriage, and let him gently out behind, off a platform which would tip up vertically and land him on his feet. There might also be apparatus which would collect his gloves and umbrella, and replace his hat on his head, after a rotatory iron and pad attached to the rear axle had given it a glossy polish. This, however, might lead to abuses by persons who would deliberately get in the way of motor-cars in order to get their hats done up free of charge. Meanwhile, a system of buffers such as are used upon locomotives, and fenders such as are used upon boats, might enable the cars to bump and jostle each other with impuuity."

IMPROVEMENTS IN MOTOR-CARS.—According to the *Aberdeen Free Press* an ingenious, and what has all the appearance of an important, arrangement in the construction of motor-cars has been devised by Mr. John T. Clark, Rose Street, Aberdeen. By this arrangement accumulator cases, containing accumulators sufficiently charged for ordinary driving purposes, are situated in a receptacle built under the bottom of the vehicle, but having all the appearance of forming part of the body of the latter, so that no unsightly appearance whatever is presented to the eye. The cab to which it is proposed to apply the new arrangement is designed like an ordinary cab, to carry four persons inside, but on the seat in front, which is covered by a neat canopy, there is room for one person on each side of the driver. Mr. Clark has also introduced a new hansom to Aberdeen which has the merit of being a distinct improvement on the usual type. Ordinarily the front of a hansom folds open in two halves, which the passenger swings outward on wishing to alight. In the improved hansom, however, the front is circular and upright—the upper part being of glass. It is in two halves, which run on grooves at the bottom and top, and on wishing to open the front the passenger simply takes hold of two handles within easy reach on either hand and slides the two halves backward—one along each side. The doors can be moved also by a handle from the driver's perch, and altogether the arrangement can be worked with the greatest facility.

*** OWING to the pressure on our space this month we are obliged to hold over many items of interest.

THE BUFFALO INJECTOR.

FOR boiler feeding feed-pumps are usually employed, but in situations such as heavy steam-operated automotor vehicles, where it is absolutely necessary to avoid unnecessary weight and to economise in space, an injector is unquestionably the thing. The advantages of a good injector are very numerous: they contain no moving parts; they are automatic; they require but little steam; they can inject at any pressure and at nearly all temperatures; they are very light; and, lastly, they are, as compared with ordinary feed-pumps, very inexpensive. Their principal disadvantage is that, as usually made, they are not very accessible for cleaning, and any substance brought over with the feed is liable to prevent their working. In order to surmount these practical objections, Messrs. Green and Boulding, engineers, of 21, Featherstone Street, City Road, London, who have had many years' experience with all classes of injectors, have placed in the market the "Buffalo" Injector, which we illustrate, and which has been designed to remedy the troubles previously referred to. The B. Class is made so as to meet all ordinary conditions, and will work either lifting its supply water or receiving under pressure without any regulation or adjustment whatover. This machine is

STEAM

SUCTION

made to work with steam pressure up to 140 lbs. per square inch. The steam and suction connections, as will be observed from the illustration, being in a vertical line, in order to examine under steam it is only necessary to slack the three connections and turn the machine on the pipes when (and this is a great feature of this injector) the forcer combining tube can be withdrawn by hand for examination or cleaning. The injector is worked entirely by one handle and is automatic, restarting in its action. For pressures above 140 lbs. and where high duty, such as warm water and long lifts, have to be encountered, the A. Class or higher grade machine must be used. This is also worked by a single lever, and the working of the machine is of the simplest character. These injectors have only been on the market some 2½ years, but they have had a very large sale, thus testifying to their utility.

As we say, we think them especially suitable for feeding the steam boilers of heavy automotor vehicles.

THE RIKER ELECTRIC CARRIAGE.

THE accompanying illustration represents a type of electric motor-vehicle which has been successfully placed upon the American market by the Riker Electric Motor Company, of New York. As will readily be understood, the car body can be of any desired kind, and the Company manufacture several different styles of body; the same type of mechanism and its arrangement is applied to all. As will be seen, the framing is tubular, the tubes being of steel and 1¼ inches diameter. The wheels are of bicycle pattern, but, of course, much stronger; the steering wheels are 30 inches, and the driving wheels 36 inches diameter, the wheel base being 6 feet. On the rear axle, which is, of course, in two parts, is the differential gear. The fore axle is in one piece, the ends projecting within the centres of the front hubs, where they are cupped, top and bottom, to receive adjustable cones which pass through the inner hub. The wheels swivel on these cones which replace the fifth wheel in the ordinary vehicle. As the upper cone, the lower cone, and the point of contact between the ground and tyre are all in a line and in the same plane, it is apparent that any obstacle in the path of the wheel would not slew it aside or affect the steering lever.

THE RIKER ELECTRIC CARRIAGE.

A motor of special design has been adopted. It is of a rectangular multipolar-frame type, with two wound and two salient poles. At one end the motor is swung by means of double-bearing clamps on the rear tube at the side of the gear casing, and at the other it is held by a double-spring suspension. The sides through which the armature projects are entirely encased by aluminium jackets having movable covers. The motor is series connected, with sectional-wound cast steel field. The armature is form wound on a slotted core, and has a large commutator. Its normal capacity is 2 kilowatts, at 80 volts and 25 ampères, but it will stand a very large overload. It weighs 142 lbs. complete, and operates at a normal speed of 1,000 R.P.M.

The desire to reduce the weight of the battery equipment while maintaining or even increasing the discharge rates obtainable with the present forms of battery has led to the development of a new lead-zinc type of storage cell. The positives of this new battery are of lead, while the negative is composed of a zigzag band of electrically deposited zinc-coated copper alternating with each lead plate. This combination gives an average E.M.F. of 2·3 volts, and a maximum of 2·5 volts. Each cell, as used in the vehicle, consists of a rubber-retaining jar, six positive plates, measuring 6¼" × 6" × $\frac{3}{16}$", weighing 28 ozs., and a single negative consisting of a zigzag zinc-copper band. The complete battery equipment consists of 36 such cells, arranged in four boxes or trays of nine each, weighing 190 lbs., and making a total battery weight of 760 lbs. Considering that this battery has at 2·3 volts per cell a 150 ampère hour capacity at a 10-hour rate, or 120 ampère hours' capacity at a 4-hour rate, the weight and size are certainly very small. A door under the rear seat gives ready access to the battery box, and the four battery trays can be easily placed or taken out, connections being automatically made.

An interesting element in connection with this vehicle is the system of electric control and regulation. At the left of the front seat will be seen an upwardly projecting lever. This lever is fitted to the spindle of the controller, which is located under the seat. A series parallel control is effected by means of this controller between the batteries and motor, giving four combinations forward and two reverse, and four corresponding speeds of 3, 6, 12, and 15 miles per hour. The controller is moved to either side of its normal position for a corresponding direction of carriage travel, the extent of movement either way determining the speed. In general construction it consists of a steel shaft, mounted on which are a number of insulated radial contact shoe arms, making various connection between a row of stationary contact terminal brushes. Aside from the operation of this controller, the driver of the carriage need not trouble himself about the proper performance of the motor or batteries.

Two brakes are provided, one a band brake acting on a brake pulley on the motor shaft, and actuated by a pedal, and the other a shoe brake, acting on the tyre of the driving wheels, and operated by an upright hand lever at the left of the front seat. This double-braking gear furnishes an element of great assurance to the operator, who can always rest satisfied that, at no matter what speed the vehicle is operating, one or the other or both of these devices is at hand.

It is intended that the batteries should be charged at about 110 volts, but, by charging through the controller with the motor cut out, it is possible to charge at a smaller potential by arranging them in other combinations. A rheostat is also provided in the charging circuit which will dissipate the surplus voltage up to 500 volts. In connecting the battery-charging cable to the supply conductor, no attention need be paid to the polarity, as an automatic switch is provided to take care of this condition. It is simply necessary to connect the conductors, the switch automatically connecting the suitable polarity to the corresponding battery terminal. As far as these features go, the mechanism seems to operate on the "you push the button, we do the rest" plan, and it does it positively and without complication. Another feature is the safety-stop lock switch, which is operated by a Yale lock and key, and turns off the main current when operated, guarding against malicious starting of the vehicle.

As a whole, this motor vehicle, intended to carry four persons, and easily capable of accommodating five, when its weight, which is but a little over 1,800 lbs., is compared to its travelling capacity, makes a very superior showing. With the normal four-hour discharge rate, it has a capacity on good roads of 40 to 50 miles at about

12 miles per hour. The storage battery does not seem to be such an insurmountable evil after all. (For many of the above particulars we are indebted to the *Electrical World.*)

ELECTRICAL ROAD TRACTION.

In country districts, where, owing to the cheapness of fuel or the convenient vicinity of a waterfall, electrical power is cheap, a form of electrical traction such as we illustrate below may be indulged in by anyone who owns a vehicle fitted with a motor. The overhead wire or trolley system is, so far, confined to tramcar propulsion but, needless to say, it is applicable to vehicles of all kinds, from a baby's perambulator to a locomotive. We hope to see the overhead wire running from one village to another, and the farmers mowing, binding, and transporting their hay, or digging and carting 'wurzels by the ubiquitous "current." There is no reason why this should not be done. In many parts of England and Scotland current can be made for the mere cost of putting down plant. As in so many other things, however, the difficulty is not physical or economical, but the sublime, ineffable, genuine, good old true British spirit of Chinese-like conservatism constitutes the barrier to progress of all kinds. And hence the country wagons roll along the roads just as they did, and of the same make and pattern as they were, 100 years ago. In the United States, where, as might be imagined, this novel and convenient method of traction originated, it has answered every expectation. The system is the invention of Mr. W. G. Caffrey, of Reno, Nevada, who has been working on the system for the past three years. A line of ordinary poles was set up near the Reno foundry, and the dynamo placed therein. The two wires were secured to the poles about 18 inches apart and 17 feet from the ground, and a trolley with a lazy tongs arrangement allowed the current to be furnished to the wagon. The problem which the inventor had to solve was a difficult one, as a perfect circuit must be maintained at all times, and the contact must be flexible enough to allow a wide divergence from the regular road if necessary.

The improved form of trolley works admirably. It consists of a metallic frame having two over-running wheels, and underneath these are the two locking wheels, which effectually prevent the top wheels from leaving the wire and still allow the frame to pass the support, holding the wire on the pole. On the lower wire a similar device is used. The two trolleys are connected by an insulated pantograph, or lazy tongs, equipped with suitable guides, thus providing for unequal tension on the trolley wires. The poles are 24 feet long and 6 inches in diameter at the small end. They are placed at intervals of 125 feet. On the inner or road side of these poles, are two supports or "pass-bys" of malleable iron. No. 0 bimetallic wires are used. The current is supplied to the wagons by cable, which runs on an automatic reel on the wagon, permitting the cable to run out 200 feet if necessary or wind up to a short length, thus allowing the wagon to follow the ordinary road and permitting it to turn or do anything required of it. The ordinary trolley pole may also be used, but the cable permits of running the wagon on either side of the ordinary road, allowing it to meet or pass vehicles without difficulty.

The four-wheeled cart shown in our engraving has wheels 48 inches in diameter. The rear wheels are fastened to a shaft geared to a spring-suspended motor. The motor is a 2 H.P. one of the Westinghouse crane type. In front of the motor a commutator controller is suspended, the handle of which is within easy reach of the person steering the wagon. The front axle is trussed, and the spindles are pivoted to the wheel hub with an arm extending forward about 18 inches fastened rigidly to the spindle. These two arms are connected, and the connecting bar again connected to the steering bar. This gives quick turning qualities with easy manipulation. The generator used was a 5 H.P. compound wound Westinghouse 500-volt dynamo. It is said that on the trial trip a speed of 15 miles an hour was reached with a load of 2,500 lbs. on the wheels. The control of both the motor and the steering apparatus was all that could be desired. The system has much to recommend it, and some of our large landowners might well give it a trial. For many of the technical details in the foregoing account we are indebted to the *Scientific American.*

ELECTRICAL ENGINEERING.

Growth and Prospects of a Great Industry.

At the annual general meeting, on the 10th inst., of the Northern Society of Electrical Engineers, Mr. John S. Raworth, M. Inst. C. E., delivered his presidential address. He pointed out that the history of electrical engineering, apart from telegraphy, is so short that probably all those present could carry the whole of it in their memory. When they entered upon the business they had practically only one commercial outlet, namely, lighting, and they were unable by any amount of sophistry to make the public believe that electric light was cheaper than gas. Now the conditions were changed, and one engineer had told him that in one town the working man and the fried-fish shop were his best customers, and was actually realising Mr. Preece's oft-derided statement that the electric light is the poor

The Trolley System adapted to Road Motor-Cars.

man's light. Even to-day the one outlet with which they started—lighting—was their mainstay, but other developments were growing so rapidly that one found it impossible to keep pace with them. For instance, electro-chemistry, old in conception, new in economic application, which was now showing such vitality that the hope—he might even say the assurance—was rising within them that Widnes and St. Helens may soon cast out the "devils" which "possess" them by redigesting their waste heaps. As to the more pressing question of tramways and light railways, hitherto they had done next to nothing, and the small experiments which had been undertaken had been carried out almost entirely with American machinery. Even under these conditions the results had been satisfactory. They must not, however, lose sight of the fact that they possessed several home-made electric tramways. The total mileage of electrically-worked tramways in Great Britain was now 93. The projected lines, however, amounted to no less than 340 miles in length, and the capital required for their equipment would certainly not be less than £3,000,000. But even this large amount of prospective business represented only the beginning of the demand. Very soon horse traction would be superseded by electricity on the whole 1,000 miles of tramway now existing; and, in addition to this, London would be honeycombed with subterranean electric railways, and provincial towns would adopt systems of surface tramways far more elaborate and extensive than those which now existed even if they had to widen their streets to accommodate them. There was already sufficient indication of what was coming in the attitude of Manchester, Leeds, Sheffield, and Glasgow. The fact was that electric trams paid both the owner and the user; wherever they ran no one could afford to walk, except for exercise, for the saving of time was enormous. Even in England, where the eight miles an hour rule was in force, there did not appear to be any difficulty in getting over the ground. What was wanted was to get rid of the horse in cities. They would then make the streets of hard asphalte as smooth as a billiard table and would keep them quite clean; the electric motor-carriages would run with so little friction that even the present batteries would fulfil all the conditions. In conclusion, the President said the keynote of his address was faith—faith in themselves, faith in electricity, faith in the new dispensation which was dawning on the world.

HUNTER'S MOTOR.

The number of oil motors which have been brought out for the propulsion of vehicles is already very large, and it must be said that as a rule they are mostly of one predominant type, differing only in slight details from each other. Mr. John Hunter, of Lewisham, has endeavoured to improve upon this sameness, and has lately brought out an oil motor which possesses several features, differentiating it markedly from others actuated in a similar manner.

Mr. Hunter has set himself the task of producing a motor which shall at once be very compact, which shall run without undue noise and vibration, and which shall have high efficiency. After a good deal of experimental work, attended with the usual disappointments and failures, Mr. Hunter has succeeded in evolving a motor which certainly fulfils these conditions with a considerable degree of success, and which is, moreover, distinguished by many distinctly novel features. We illustrate this motor in the accompanying drawings, of which Fig. 4 (*see* p. 149) represents the general external appearance; Fig. 1 is a side elevation partly in section; Fig. 2 is a plan also partly in section; while Fig. 3 is an end view.

As will be seen, the motor comprises two cylinders, C and C[1], each fitted with radiating gills, coupled to the central crank chamber, A, in which the cranks revolve. By the ordinary means the connecting rods turn the shaft, B. The cranks, by the way, are placed at angles of 180° with each other. Clearance is avoided as much as possible, but a pipe, D, connects the ends of the cylinders, and this forms a chamber, or rather two chambers, through which the explosive energy of the ignited gas and air is transmitted. These two pipes meet in a firing chamber, E, which is subdivided into two chambers, e^1 and e^2, leading to the exhaust and inlet passages, *g* and *h*, and opening respectively by means of the valves, G and H, into this chamber, E. This valve, G, is held on its seat by a light spring, and it allows the charge to be drawn in by the piston when not under compression. The valve, H, is also held to its seat by a spring being opened at the right moment so as to allow the waste products to escape through the discharge outlet, *h*. The exhaust is opened by means of the tappet, I, which again is actuated by the cam, K, which is geared with the crank spindle and revolves at half the speed of the latter. The firing of the charge is effected by an electric ignition; but whereas the method usually adopted consists in the employment of a direct current, Mr. Hunter effects his ignition by means of the secondary coil of a Rhumkorf inductorium. In this way he gets a spark of high potential, and with more certainty of obtaining it. The make and break, instead of being made by the magnetic action of the soft-iron and attracted armature, is effected by a lappet arrangement shown at F. If desired, ignition can be effected by a hot tube or other means. The motor, it is needless to say, acts on the Beau de Rochas or Otto cycle, and the sequence of the operation is as follows:—The explosive charge is drawn through the valve, G, on the outstroke and fills the outer ends of the two cylinders and the chamber and passages, forming an open communication between them. The charge is then compressed on the following instroke and fired. The explosion acts on both pistons at the same time, and when the pistons have reached the other end of the stroke the exhaust valve, H, opens, thus completing the cycle.

The idea underlying this system is that the shock of the explosion is neutralised by acting on both pistons at the same time, thus reducing or destroying the vibration. That this is effected to a very great extent is undoubtedly true, as we have witnessed. Another point is that the firing of the explosive charge being effected in the passage connecting the two cylinders, which passage is always at a high temperature, there is thus little loss of efficiency through the cooling of the expanding gases. By this means also the cylinders do not become unduly hot.

We have lately witnessed some trials of this motor and were much impressed with its lightness and compactness. It gives off about $3\frac{1}{2}$ H.P. at 800 revs., and weighs but 140 lbs.

FIG. 1.

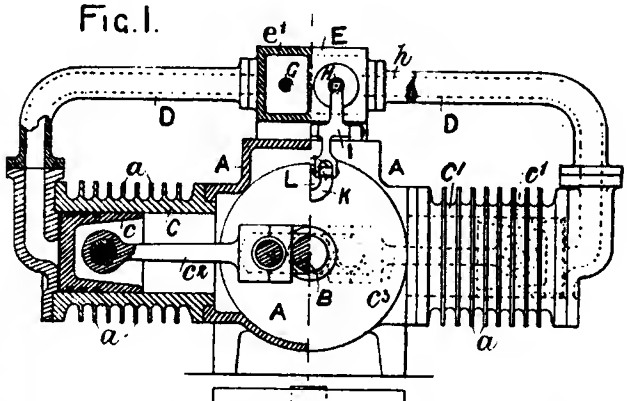

FIG. 2.

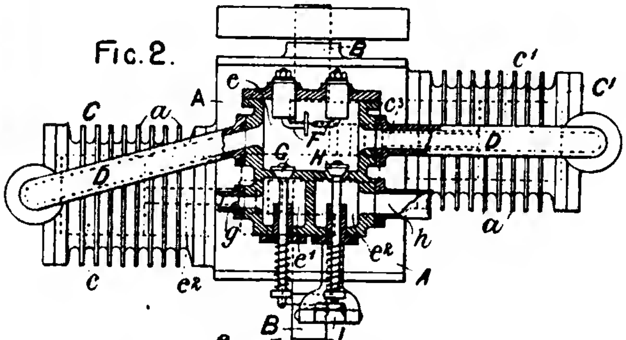

FIG. 3.

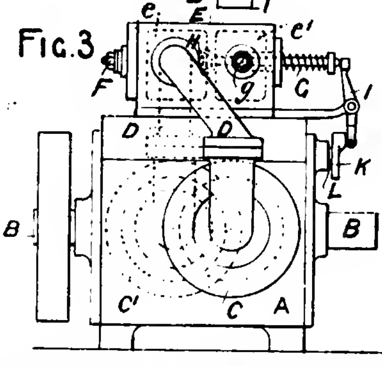


Mr. Hunter is at present perfecting the gearing for attaching the motor to a light carriage. In conclusion, we are bound to say that we were favourably impressed with the lightness, compactness, and simplicity of this motor, and shall be glad to know that its manufacture is a commercial success.

New and Mayne (Limited).—The scheme of arrangement in this matter was on the 12th instant before Mr. Justice Wright, in the Chancery Division of the High Court of Justice, when the scheme as set forth in a recent number of this Journal was duly approved by his Lordship, subject to the filing of proper evidence that the meeting approving of the scheme was duly convened.

CORRESPONDENCE.

⁂ We do not hold ourselves responsible for opinions expressed by our Correspondents.

⁂ The name and address of the writer (not necessarily for publication) MUST in all cases accompany letters intended for insertion or containing queries.

AUTOMOTOR VEHICLES AND STABLE BOYS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—In the December issue you say in a postcript to Dean Tait, D.D., that it is possible to get a motor-carriage for two in which there will be no objectionable features and which will be easily handled by a stable boy. Would you kindly send me maker's name and address of place where I can get such an article, as I think of getting one?—Yours truly, A. E. Flaxman.

P.S.—I, too, am a constant reader of your journal.

[If our correspondent will consult The Automotor Pocket-Book for 1898 he will find complete lists of makers. If he have not this

Fig. 4.—Hunter's Motor.

at hand, we would suggest that he consult Messrs. Roots and Venables, Westminster Bridge Road, London, S.W.; the Lifu Company, Cowes, Isle of Wight; or the Daimler Company, Shaftesbury Avenue.—Ed.]

THE GREAT HORSELESS CARRIAGE COMPANY.

To the Editor of The Automotor and Horseless Vehicle Journal.

Dear Sir,—There are a few things in the speech made by Mr. Lawson at the Great Horseless Carriage Company meeting which we do not think are quite logical. Would you allow us to bring these to the notice of your readers, many of whom are shareholders in this concern?

A shareholder at the meeting remarked—and it appeared to us a very sensible remark—that if they were not able to build electric motor-cabs they ought to be. Mr. Lawson agreed with the remark, but he was careful not to give any explanation why the Company were not in a position. He is a director, and has had a considerable lot to do with the management and ought to know. Mr. Lawson says there is *room* at the works for putting £5,000 to £6,000 heavy machinery down: may be, but can he or anyone show a reason for spending all this money? We were told by a former chairman that the works were full of machinery; and, from what the writer saw of the place last July, it certainly had the appearance of being ready to turn out plenty of work, but any work that is done does not seem to be for sale. At least, we wanted to hire a machine with a view to purchasing (last July), and were simply told that they were not in a position to supply motor-vans, though we saw some about. We believe they have a great many made now, and still they are not selling them.

Can anyone explain this? Since then we have got a parcel-van from the London Motor-Van and Wagon Company on hire, with a view to purchase, and if the Great Horseless Carriage Company had been alive to the business they might have had the order.

Another remark made by Mr. Lawson was that they could either build the electric cabs in their own or other works. This seems absurd—to say you have works of your own doing nothing and giving the work to other firms. No private firm would do anything so absurd who was alive to its own interests. Mr. Lawson was good enough to say also that "they would have to continue to be customers of the Daimler Company, because the Daimler were good customers of theirs."

The Daimler Company are customers of ours simply because it suits them, and when they find that they can do better elsewhere they won't remain customers a day or an hour longer. We should do the same, and being tied down to any concern like this is detrimental to its prosperity. It cannot succeed. We regret that none of the shareholders at the meeting referred to these points, and if you will kindly bring these matters to the notice of your readers, many of whom are shareholders, we should feel greatly obliged.

We think if we have men on the board of sound business principles and common sense it will succeed, but so far, what has struck us as being lacking badly is a little ordinary business sagacity and business management.—Yours faithfully,

pro John Love, Jr., & Co.,
J. L.

AN APPRECIATION.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Will you please forward two copies of your Automotor and Horseless Vehicle Pocket-Book, for which we enclose 3*s*. 4*d*.

We are always interested in your paper, and in the thorough way you report and illustrate everything connected with automobilism. Wishing you every success in the New Year.—Yours faithfully,

Didsbury, Manchester. Simpson and Bodman.

THE POST OFFICE MAIL VAN.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—We have now completed four weeks of our contract under the Postmaster-General for conveying Her Majesty's mails by steam motor-van from London to Redhill, and thus far all has been most satisfactory.

We began on December 16th, and, as you know, are timed to leave Mount Pleasant Post-office at 10.30 p.m., and to arrive at Redhill at 1.42 a.m., returning to Mount Pleasant Post-office at 4.45 a.m.; but we have generally been able to get in from 15 to 30 minutes before time both on the outward and return journeys, and on December 30th we made our record run, when we reached Mount Pleasant at 3 45, as against 4.45.

Our arrivals during the first two weeks have been as follows:—

Dec. 16th.	Arrived Redhill	28	minutes before time.	
	Returned Mount Pleasant	18	" "	
" 17th.	Arrived Redhill	32	" "	
	Returned Mount Pleasant	16	" "	
" 18th.	Arrived Redhill	34	" "	
	Returned Mount Pleasant	18	" "	
" 19th.	Sunday. No run.			
" 20th.	Arrived Redhill	34	" "	
	Returned Mount Pleasant	15	" "	
" 21st.	Arrived Redhill	34	" "	
	Returned Mount Pleasant	10	" "	
" 22nd.	Arrived Redhill	33	" "	
	Returned Mount Pleasant	12	" "	
" 23rd.	Arrived Redhill	29	" "	
	Returned Mount Pleasant	14	" "	
" 24th.	Arrived Redhill	27	" "	
	Returned Mount Pleasant	18	" "	
" 25th, 26th, and 27th.	Christmas holidays. No run.			
" 28th.	Arrived Redhill	20	minutes late.	Joint
	Returned Mount Pleasant	25	" "	broke.
" 29th.	Arrived Redhill	19	minutes before time.	
	Returned Mount Pleasant	35	" "	

We have thought you might be disposed to give a short notice of the success of our steam motor-vehicle for mail traffic, this being a matter of considerable public interest. Thanking you for your valuable support, we are, yours faithfully,

JULIUS HARVEY AND CO.

[Most satisfactory in every way.—ED.]

SPEED GEAR.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—On p. 97 of your December issue you refer to M. Mors having introduced a *variable* speed gear, stating that you had not yet seen what might logically be described as such. But you are of opinion a change speed gear is that meant. The distinction is a little too subtle for me. In your October number you refer to M. Pretôt's speed gear as a variable speed gear, and one of the best designs you had seen. Are you of the same opinion still; and do you think the Pretôt autocar has a future for it? It seems to be a favourite in Paris.—Yours faithfully, Y. Z.

January 11th, 1898.

[Our remarks upon the Mors Speed Gear seems to have attracted a good deal of notice, not only from you but from other correspondents. The only variable speed gear that we know of which can be strictly called "variable," in the sense that any desired variation can be obtained within the limits of the mechanism, is that known as the Houldsworth gear, as used in cotton-spinning factories. The Pretôt speed gear gives a large number of definite speeds within the limit of the machine, but unlike the former the speed cannot be varied indefinitely. The ordinary speed-changing devices give a small number of definite changes. In mathematical language, in a real variable speed gear the differential coefficient $\frac{dx}{dy}$ should be infinitely small, whereas in the ordinary speed-change gear this is definitely large. We intend to discuss this subject at length in a near issue. We think that the Pretôt automotor-vehicle stands as good a chance of obtaining popularity as any other. We do not see why it should not.—ED.]

SIX-WHEELED VEHICLES.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—In his lecture before the Liverpool Self-Propelled Traffic Association on November 26th last Mr. Worby Beaumont hinted that "a form of vehicle with six or eight wheels, all dirigible, must be designed." May I remark that a simple design for a six-wheeled vehicle has been already published in the correspondence columns of the AUTOMOTOR, viz., fore and aft steering with central driving wheels. A. J. A.

December 20th, 1897.

[We should very much like to see a six or eight-wheeled vehicle, all wheels dirigible, and the whole vehicle complying with the Locomotives on Highways Act as regards weight.—ED.]

THE DE DION TRICYCLE.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—Having seen that the De Dion Company, of France, are supplying their 1¼ H.P. motors without the tricycle, do you think it possible to get one here? Could you tell me the maker in England (I am assuming that the Company have sold their patent rights to a firm here); if not, could you oblige me with the De Dion firm's address in France? I think your suggestion as to a central depôt for the sale of motors and parts would give good results if carried out. The AUTOMOTOR is the most interesting and useful I read, and I would gladly remit if double the cost.—Yours, &c.,

Nelson, Lancs. W. BARRACLOUGH.

[Apply to the Beeston Motor Company, Cheylesmore, Coventry, or to MM. De Dion et Bouton, Puteux, Seine, France. Glad of your good opinion.—ED.]

SERPOLLET BOILER.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—I have for some time been experimenting with a flash boiler of my own design and construction, but have met with only partial success, due to the fact that I have unfortunately made the tubes too thin, a grave error in a boiler of this type, as I now realise. I have determined to construct a second boiler upon the same lines, but before doing so wish to arrive definitely at the proper heating surface necessary per I.H.P., and also the thickness of tube required. My present tubes are ¼ inch thick, but I find that in increasing the feed beyond a certain limit the tubes gradually become cooled, and saturated steam is the result.

Farman, in his description of the Serpollet tramway system, gives the heating surface of the boiler as 43 square feet for engines developing 20 I.H.P. Does not this seem low in comparison with the power developed? Again, in your article on the Serpollet light locomotive in the AUTOMOTOR of November, the heating surface is given as 11·32 square metres, which, I think, is about 120 square feet, which differs considerably from Farman, although I confess I do not quite see how such a great area of heating surface can be obtained from the 44 tubes which comprise this boiler.

I hope I have not intruded too much upon your time with these queries, but as I intend to go into the car industry as soon as I can obtain satisfactory results from this form of generator I shall take it as a very great favour if you can oblige me with the information I require. If you can answer me privately I shall be greatly obliged, as it is some time yet ere the January number comes out.—Yours truly, JNO. SIMPSON.

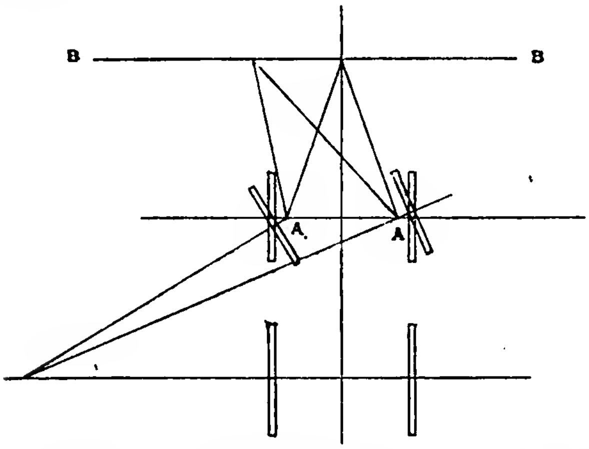
[We have verified our figures relating to the Serpollet boiler, and we now repeat them:—Grate area, 46 square decimetres = 4·95 square feet "surface de chauffe." Furnace, *i.e.*, heating surface, 11·32 square metres = 121·8 square feet. Weight of boiler, 2,850 kilos. = 6,270 lbs. From this it will be seen that the ratio of grate to heating surface is 1 : 24·6, which quite agrees with ordinary marine practice. As regards the I.H.P. per square foot of grate, the figures given by our correspondent give ·465 I.H.P. per square foot of H.S., which is high compared with, say, the "Economic" boiler, by Mr. Davey Paxman, which only gives ·154-·185 I.H.P. per square foot of H.S. On the other hand, the comparison between H.S. and I.H.P. is, in small motors, always unsatisfactory. Your better plan would be, we think, to base your H.S. upon the pounds of water evaporated per B.H.P. per hour, and lastly allow an ample margin on everything. We cannot reply to correspondents privately as this would be contrary to all recognised journalistic practice, and, besides, very inconvenient. We mention this for the benefit of others, whom we would ask to observe another newspaper canon, and that is, to write on *one* side of the paper only.—ED.]

DAVIS'S STEERING GEAR.

To the Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.

SIR,—In the notice of my steering gear which you have been good enough to give, no reference was made to the geometrical principle of the arrangement. Of course, most of your readers are familiar with the arrangement of independently pivoted wheel arms on a steering axle, but my system, I believe, is the only one that secures accuracy of alignment, instead of an approximation, for all positions. The control, too, of the wheel arms is better than with link-work steering gear, because the leverage increases with the angle of lock, instead of becoming less, as is the case with previous gears of this type.

As the method to be used in the alignment of my gear may be of interest to your readers, may I ask you to insert the following short description?



Let the figure represent a plan of any proposed road-carriage in diagram form, AA being the pivots of the steering wheel arms. Draw a line, BB, parallel to the steering axle and as far removed from it as one axle is from the other. Cause the lines that represent the steering tillers to intersect on this line and also on the centre line of carriage. This gives the position of the wheel tillers for a straight course. For all other positions the wheels will be found to be correctly placed if the lines representing the steering tillers meet in some point on this parallel line—I am, Sir, yours faithfully,

115, Lewisham Road, London, S.E., HENRY T. DAVIS.
December 29th, 1897.

[Our correspondent is mistaken. Reference *was* made, and very clearly too, to the geometrical principle of the arrangement. We thus stated it (*see* p. 110 of the December number):—"The two wheels must make some angle with each other, and this angle will vary as the ratio of the beam or distance between the two fore wheels and the radius of the curve. In fact, each wheel is tangential to its own radius." The latter sentence would read better if we say "each wheel," *i.e.*, the vertical plane as represented by a wheel, "is normal to its own" radius. This is the simple and sole geometrical principle involved. The line, B'B, is unnecessary, in that it has no geometrical connection with the positions of the two fore wheels. If the gear ensures that in all positions the normals to the vertical planes of the wheels always intersect in the same point, then it undoubtedly has merit, but unless this condition be fulfilled exactly, more or less side-slip will be produced. Whether this condition is or is not fulfilled, we, of course, cannot say.—ED.]

WE understand that the Lambeth Vestry have authorised the Wharf Committee to purchase three motor convertible dust and water vans.

President	Sir DAVID SALOMONS, Bart.
Secretary	ANDREW W. BARR, Esq.

SELF-PROPELLED TRAFFIC ASSOCIATION
(INCORPORATED).

THE annual meeting of the Self-Propelled Traffic Association took place at the Cannon Street Hotel on the 20th December last, and, after the reading of the notice and of the minutes of the previous meeting, was adjourned until January 20th inst., at 3 o'clock, at the same place.

LIVERPOOL CENTRE.

Programme for 1898.

January 25 ..	Paper: "Some Points in the Design of Automobile Vehicles intended for Heavy Traffic." Mr. GEO. H. LITTLE, Technical Editor of THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL.
February 8 ..	"An Account of our Trials and Experiments, with the Conclusions drawn therefrom." Mr. D. S. SIMPSON and Mr. W. L. BODMAN, Joint Authors.
February ..	"Steel Springs." (Date and author in abeyance.)
March 29 ..	Paper: "Recent Improvements in Accumulators and in their Application to Traction on Common Roads." Mr. J. T. NIBLETT.
April 19 ..	Paper: "Arrangements for the May Trials." The HONORARY SECRETARY.
May 24–27 ..	Trials of Motor Vehicles for Heavy Traffic.

THE paper on "Leather Tyres," which it was hoped would be read next month by Mr. Henry S. Fearon, Assoc. M. Inst. C.E., has been postponed to the 1898–99 session.

The May Trials.—A number of preliminary arrangements have been dealt with during the last few weeks, and it is probable that important announcements relative to (*a*) judges, (*b*) subscriptions to guarantee fund, (*c*) foreign vehicles, and (*d*) the general programme, will be made in our next issue.

Mr. W. Hugh Woodcock on Roller Bearings.*

So many papers have lately been read on the subject of roller bearings, that the author fears it will be difficult for him to introduce any new matter before the members of this Association, particularly as most of the recent papers refer to results obtained from the same series of experiments as form the foundation of this paper. On the other hand, the subject is attracting such general interest at the present moment that he ventures to hope his paper may prove of interest, even though it be not free from the defect of recapitulation.

It is, in the first place, advisable to obtain clear ideas as to the main difference existing between rolling and sliding motion, as we can only thus form a true estimate of the advantages to be derived from the application of the former, in place of the latter, to bearings. Perhaps the simplest illustration of the efficiency of the two forms of motion, as measured by the resultant resistance, or friction, and which at once shows the advantage of the former, is the difference in the force required to draw a load upon a level road, when carried upon wheels which are free to revolve, as compared to that required to draw the same load on the same wheels when skidded—the former being rolling, the latter sliding motion. The wheel is certainly the most general application of rolling motion, and no one would think of comparing its high efficiency as a load carrier, where heavy loads have to be transported over more or less uneven surfaces, with that of the sledge runner, which may be said to represent sliding motion.

Another simple illustration of the same fact—if the palms of the hands be slightly pressed together there will be found considerable resistance to movement of the one over the other, but if a pencil or roller be placed between them the lateral movement becomes easy.

The object of roller bearings is to apply the same form of motion between wheels and their axles, or between revolving shafts and their bearings, as now exists between wheels and the surfaces upon which they roll.

The comparative amount of the friction arising from the two forms of movement is simply shown by placing a roller on a true plane with its axis at right angles to the direction of movement, and then gently raising one end of the plane until movement of the roller takes place by rolling; the angle that the plane then forms with the horizontal is the "limiting angle of friction" for rolling motion, and will be found to be very much less than that which will be necessary to cause movement of the same roller, when its axis is placed parallel with the direction of movement, or where movement takes place by sliding.

The coefficient of friction, in either case, is equal to the tangent of the limiting angle, or, in other words, if we consider the surface on which movement occurs as being the hypothenuse of a right-angled triangle, the base of which is the horizontal, then the coefficient of friction is equal to the perpendicular of such triangle divided by its base. The difference of this coefficient, though varying considerably with the materials experimented upon, may, for hard and polished surfaces, be taken as much as 12 to 1 in favour of rolling motion.

The French physicist, Coulomb, more than a century ago, determined the law of rolling friction, which may be stated as under:—

"So long as the wheel (or roller) and the surface on which it rolls is uninjured, the resistance (or friction) is proportional to the weight, and diminishes as the diameter of the wheel, or roller, increases."

Or, practically, the surfaces must be kept uninjured, and the rollers as large as possible.

It is generally accepted that with hard materials, such as metals within the limit of abrasion, friction varies only with the pressure, and is independent of the extent of surface, time of contact, and velocity.

The reason for the great difference in the coefficient of friction is that in the case of loads resting on rollers the combination is always in a state of unstable equilibrium, whereas when resting on plane surfaces it is in the condition of stable equilibrium.

In the case of bearings, if a load be imagined to rest on a perfectly cylindrical roller, which in its turn rests upon a perfectly cylindrical journal, and assuming that no distortion of the touching surfaces takes place, the slightest horizontal force applied to the load will destroy the equilibrium of the combination, and movement of the load will take place. Although in practice it is impossible to obtain the above conditions, as there must be some distortion of the touching surfaces, even when under comparatively small loads, the amount of force required to overcome the equilibrium is very small compared to that required when the load is resting on surfaces that have, before movement can take place, to slide one upon the other. Undoubtedly good lubrication very materially reduces the coefficient of friction in sliding movement, as lubrication may be considered as providing an infinite number of small particles, or rollers, placed between the moving surfaces, whereas lubrication acts rather as a retardation than otherwise to rolling motion.

The above is a short statement of the difference between rolling and sliding motion.

Mr. W. Bayley Marshall, M. Inst. C.E., in his paper read before the British Association at Toronto last August, stated that the requirements of a satisfactory roller bearing may be described as under:—

1st. That the various parts must be proportioned with reference to their relative movements so that nothing but rolling motion takes place between the surfaces engaged; and beyond this, that they must be constructed of materials suitable to withstand the stresses imposed upon them.

2nd. That the bearing rollers must be kept parallel with the axis of the axle or journal upon which they roll, that they must not be allowed to touch each other, and that they must be of sufficient diameter and length to bear the fatigue of the duty they have to perform.

3rd. That adequate provision must be made to meet the end thrust, or tendency to lateral movemont, not only of the rollers and other moving parts themselves, but also of the axle, or shaft, when revolving within a fixed bearing, or of the bearing itself, when revolving upon a fixed axle.

4th. That the bearing as a whole must contain as few working parts, and that these parts must be as simple as possible, and that they must be so designed that they can be applied and adjusted by any intelligent workman.

5th. That in applying the bearings to existing vehicles or shafts, as little alteration as possible is required to be made in the connections, such as axle-box guards, spring seating, pedestals, wheel hubs, &c.

6th. The most important of all, from a commercial point of view, that the bearings shall be produced at reasonable cost, that they can be trusted to work without special attention, and that they are capable of performing an extended duty either in mileage or number of revolutions, at small charge for maintenance.

In the author's opinion the above statement cannot be improved, but he ventures to amplify it by the following remarks. As to requirement No. 1, a simple method of determining whether the moving parts of any roller bearing have nothing but true rolling motion is to consider each such part as a unit in a train of toothed gear, the pitch of the teeth in which is infinitely small; if the diameters are then found to be relatively correct, the moving parts will truly roll upon each other. Upon the fulfilment of the second part of Mr. Marshall's first requirement greatly depends the success of roller bearings in practice. Where permissible, it is of undoubted advantage to have all the moving surfaces of polished, hardened steel, or case-hardened wrought iron, as such materials produce the least friction, and have the greatest resistance to wear; it is not often possible to use only such materials, and this by reason of the cost of manufacture. It is interesting to note that polished, hardened journals are now being used on the Great Western Railway for carriage stock fitted with ordinary bearings, and that the best wrought-iron axles for road vehicles have long been provided with case-hardened arms. Where it is not possible to use such high-class materials, the best results, so far as the author's experience goes, have been obtained by using cast steel for the casings where heavy loads and high velocities have to be resisted, as in the case of railway bearings, and hard cast iron (cylinder mixture) for lighter loads, or lower velocities; such as tramway and ordinary shaft bearings.

The rollers, when running on unhardened steel journals, should be of polished steel of a quality slightly softer than that of the journal, so that in the long run the rollers wear rather than the journal, it being a comparatively small expense to renew a set of rollers, whereas if the journal has to be turned up, this necessitates a new set of rollers of larger diameter than the original ones, added to the cost of turning up the journal.

Requirement No. 2.—The devices which have been tried for spacing and keeping the rollers parallel are so numerous that it is only possible, within the limits of this paper, to glance at a few representative ones.

Many attempts have been made to space the rollers by placing balls or subsidiary rollers between necks formed on the main rollers, one such ball or roller being placed at each end between each pair of

* Excerpt from a paper read before the Liverpool Section of the Self-Propelled Traffic Association.

main rollers, so that there are twice the number of balls or subsidiary rollers in any bearing than of main rollers. The objections to all these arrangements are that there is a strong tendency for the balls or subsidiary rollers to fly outwards by reason of pressure and centrifugal force, and that when such tendency is met by the introduction of floating rings, there is nothing to prevent the whole combination taking a spiral form on the journal which, if once set up, is fatal to the good running of the bearing. To overcome this last objection, in some devices the spacing subsidiary rollers or balls are connected or formed at the ends of rods, thus compelling both ends to move at the same velocity. When this is done and the floating rings are also introduced, a form of bearing is obtained which is theoretically perfect so far as its movements are concerned, and which has given most excellent results in practice. By the kindness of Mr. Cottrell an example of this form of bearing is exhibited here this evening. The objections to this form are, however, very serious, viz., the bearing must be made with extreme accuracy, there are a great many working parts, they require skilled workmen to put them together, and last, but not least, they are very costly.

The next device for spacing the rollers, and which in the author's opinion is the one most likely to survive, is the floating cage. This is shown on the diagrams and in most of the models and bearings exhibited here this evening. Its great recommendation is its simplicity, and the ease with which bearings so constructed can be taken off and replaced in position. It is true that in this particular form of bearing there is a certain amount of sliding friction. This amount, is, however, very small, it being only that resulting from the force sufficient to overcome the resistance of the cage to revolution, no part of the load being carried by the cage.

It should be borne in mind that the number of revolutions of the cage is considerably less than that of the axle or journal; the absolute relation in this respect depends upon the proportion of the diameter of the journal to that of the rollers, taking the ordinary proportions in railway bearings, where the rollers are slightly less in diameter than half the diameter of the journal, say 1⅝-inch rollers for 3¾-inch journals. The journal revolves three times to one revolution of the cage.

As to the second part of Mr. Marshall's requirement No. 2, namely, that the rollers must be of sufficient length and diameter to bear the fatigue of the duty they have to perform, it is difficult to lay down any hard-and-fast rule. It is, however, advisable in determining the diameter and length of rollers for any given duty, to assume that the whole of the load is at certain times borne on one roller. The question of velocity is also of great importance as affecting the fatigue of the metal.

The resisting power of the roller, so far as the author's experience goes, increases as the square of its diameter, and with journals and rollers of unhardened steel he does not recommend that a greater load than 2 cwt. per lineal inch should be placed upon rollers of ¾-inch diameter, or 8 cwt. per lineal inch of rollers of 1½ diameter. Taking a case of a railway bearing carrying 3 tons and where rollers of 1½ diameter can be used, the length of such rollers should not be less than 7½ inches.

Requirement No. 3.—There are several methods by which the end thrust of a bearing can be controlled, but to do this simply and effectually is not so easy as might be thought. In railway and tramway bearings the end thrust can be taken on a pad inserted in the end cover of the bearing, this pad being made of phosphor-bronze or other suitable material; when this is done there is, of course, nothing but sliding or scrubbing friction between the end of the journal and the pad. In cases where the end thrust is excessive, as for instance where long fixed wheel bases are used in railway work, an anti-friction arrangement can be introduced consisting of a ring of balls or, what is more satisfactory, a series of cones between the end of the journal and the cover of the bearing. A simple arrangement of cones running in a floating cage has been devised for vertical and thrust bearings, and a modification of this can be adapted to take the end thrust in horizontal bearings, whether for axles or shafting.

Requirements Nos. 4 and 5.—These are so evident that they need no special mention from the author.

Requirement No. 6.—This is to a great measure dependent upon the more or less successful fulfilment of Nos. 4 and 5, as it is impossible to produce a complicated bearing at comparatively small cost, added to which simplicity is imperative in mechanical arrangements which are required to work without special attention, and at small cost for maintenance. After describing the results obtained with roller bearings on railways, the author proceeded :—

In tramway working the tractional force necessary to start a car and maintain its speed is very high, probably only the horses know how high.

It has been endeavoured to get some reliable estimate of what this tractional force is, but it is found that authorities differ widely, owing mainly to the varying conditions under which the experiments have been made. Mr. D. K. Clark, in his work on tramways, gives as an average 25 lbs. as the tractional force required to keep one ton moving continuously, and the starting effort as 50 lbs. per ton, or double the tractional force.

The above figures are, however, subject to great variations, and it is proposed later on to put the results of some tests before you, that have been made to demonstrate the advantages of fitting tramcars with the bearings under consideration.

For the present it will be admitted that the work the tramcar horse is asked to perform is very severe, and although his daily mileage (about 12 miles) is not high, his life is short, which fact is no doubt due to excessive strain.

The cyclist has been put much in the same position as a horse, but has the advantage of being able to speak and demand alleviation. He very early discovered the advantages to be derived from roller bearings, and the universal adoption of the ball bearing for cycles is the result.

The ball bearing, however, admirable as it is for the light weights carried on the cycle, has never succeeded under heavy loads, owing mainly to the fact that all the weight is carried by only one or two balls at any moment of time, and the balls only touch the races, or ball paths, on a point, the result being as before stated that either the balls crush or the races are indented.

Lubrication is not required for rolling motion, as is shown by the fact that we do not put oil or grease on the rail; and yet the periphery of the wheel, where it is in contact with the rail, has a much greater speed than has its boss where it touches the journal, but this latter requires much lubrication, the explanation being that in the first case there is rolling motion, and in the second sliding or scrubbing motion.

Gravity Test.

A tramway-car fitted with ordinary bearings and weighing 2 tons 15 cwt. was let loose from a point 56 feet up an incline, with 1 foot 6¼ inches rise. It ran down this incline and 57 feet along the level line at foot of same, or a total distance of 113 feet. The force expended was, therefore, 6,160 lbs., falling through 1·521 feet, or 9,364 foot-lbs. The average frictional resistance was 9,364 ÷ 113, or nearly 83 lbs., equal to 30·5 lbs. per ton, the coefficient of friction being ·0134.

A similar car fitted with roller bearings being let loose from the same point ran the full length of the level line available, namely, 320 feet, and had not then quite come to rest, the total distance traversed being 376 feet. The force expended was again 9,364 foot-lbs. The average frictional resistance was 9,364 ÷ 376 = 24·9 lbs., or about 9 lbs. per ton of load, and the coefficient of friction ·004, a saving of 70 per cent.

The following figures are of interest, and are founded on the results of actual experiments :—

Relative starting effort of a tramcar on a gradient of 1 in 20—ordinary bearings 100, roller bearings 77, saving 23 per cent.; on a gradient of 1 in 80—ordinary bearings 100, roller bearings 50, saving 50 per cent.; on a gradient of 1 in 140—ordinary bearings 100, roller bearings 39·6, saving 60·4 per cent.—results which require no comment.

Roller bearings have been fitted to many horse cars, with results most beneficial to the animals employed, and it is estimated that the use of them would so prolong the life of the horses, that the reduction in their depreciation alone would show a saving of considerably over £10 per car per annum.

The Corporation of Blackpool have had some of their tramcars fitted with roller bearings, and these cars have been running on their electric tramway for over three years, with results so satisfactory that they have applied similar bearings to all the new cars which have been constructed since the advantages of these bearings were established, and their consulting engineer some short time ago certified that at least 30 per cent. of electrical output is saved by the use of such bearings, as compared with those in ordinary use.

There remains the question of first cost, which is undoubtedly high. On this question let us look back for a moment to first principles. What is the object of a railway or tramway? It is to reduce "traction" by the use of a smooth and hard surface.

If it be worth while to spend £5,000 a mile on the construction of a tramway for the purpose of reducing traction, and that this can further be materially reduced by the use of any appliance for improving the carriage which is to roll on this costly road, it would be taking a narrow view to question the first cost of that appliance when it is insignificant as compared with the cost of the tramway, or even with that of the tramcar.

There are many ways of realising the undoubted advantages in traction, so as to pay for the greater first cost of the roller boxes, and also to improve the dividend-paying power of Companies when these boxes are used, thus:—

1. Leave the number of horses as they are with their daily mileage and food, and take the saving in the longevity of the horses.
2. Increase the speed and so reduce the number of cars and drivers to work a given service.
3. Substitute two mules for two horses and make the saving in the first cost of the mules and in their keep.
4. Reduce the number of horses required by increasing their mileage per diem.

The last method is the most profitable way of turning to account the saving to be gained by the roller bearing.

Taking a hypothetical case of a line of tramway six miles long, with a 10 minutes service all day, and assuming that it takes a car 2 hours and 20 minutes to make the round journey, there will then be 14 cars on the road when in full work, and supposing that the first car leaves the depôt at 8 a.m. and the last at 9.50 p.m., then there will be 84 car journeys per diem, and the total car mileage will be 1,008 per diem. If each pair of horses is worked 12 miles per day with one day off in seven, then the total number of horses required to work the foregoing traffic will be 196.

If by the introduction of roller boxes the traction is so much reduced that each pair of horses is able to travel 16 miles per diem with six days off in 28, then the total number of horses required to work the traffic will be 160, showing a saving of 36 horses or 18·4 per cent., which at the rate of £55 per horse per annum for keep and renewals would show a total saving of £1,980 per annum, or say 1¼*d.* per car mile, without considering the saving in the cost of lubricant.

The Board of Trade Return on Tramways, September, 1893, shows that a saving of only 1*d.* per mile run would increase the net receipts by nearly £300,000, and convert many failing concerns into dividend paying properties; the published report shows that the capital expended on tramways paying no dividend is more than £1,750,000.

Tramway working expenses absorb so large a proportion of gross receipts that any saving in the latter soon becomes appreciable in the dividend payable; 55 per cent. of the average 80 per cent. representing total expenses, is due to horses, showing that that is the item where saving will be the soonest appreciable in dividend.

Assuming a tramway paying 5 per cent. dividend with 80 per cent. working expenses, then 20 per cent. gross receipts is equal to 5 per cent. dividend; a reduction of 4 per cent. working expenses will equal 1 per cent. dividend.

Now, taking 55 per cent. of the working expenses as due to horses, and reducing the number of horses by 18 per cent. as above, there should be a saving of 18 per cent. of 55 per cent., or about 8 per cent. of total working expenses, reducing them to 72 per cent., and increasing dividend to 7 per cent. instead of 5.

Road Vehicles.

With reference to the application of roller bearings to vehicles running upon ordinary roads, it is impossible to estimate the saving, as the tyre friction of such vehicles varies so considerably. A committee of the Society of Arts reported some years ago that a loaded omnibus showed the following resistance on various roads:—

Description of road.	Speed (miles per hour).	Resistance (lbs. per ton).
On macadam, new granite ..	3·51	101·09
On macadam, graveled ..	3·45	44·48
On wood paving	3·34	41·60
On asphalte paving	3·56	27·14
On granite paving	2·87	17·41

Showing a variation of nearly six to one. No doubt when this report was made the asphalte and wood pavings were not so good as at present.

A glance at the above table shows the wisdom of using granite paving where heavy loads have to be dealt with. The application of roller bearings to the wheels of road vehicles will undoubtedly greatly reduce the force required to propel them, the percentage of such saving depending upon the character of the road.

The reduction of the starting effort must, however, be of great advantage in all cases of self-propelled vehicles, and especially so when the motive power is electricity.

The simple form of roller bearing exhibited here this evening, namely, that with the floating cage, will, in the author's opinion, be found to most satisfactorily resist the shocks arising from the inequalities of ordinary roads, this opinion being founded upon results obtained from their application to agricultural implements.

PROCEEDINGS OF TECHNICAL SOCIETIES.

Mechanical Propulsion on Canals *—(*concluded*).

Towing by Locomotive.—The last method of traction to be considered is towing by means of a locomotive running on the bank. Some experiments on this plan were made by the Prussian Government during a period of four months upon the Oder-Spree Canal, over a distance of 1·86 mile which was purposely chosen on account of the number of windings it contained. Although up to the present no conclusive results have been obtained as to cost, yet, judging from former experience and from the calculations given, it would be too high to stand competition, even for regular and extensive traffic. In France, however, a service of this kind was working for several years on the Neufossé, Aire, and Deûle canals, between Les Fontinettes and the neighbourhood of Douai, over a distance of 47·8 miles with only a single lock. The locomotive was used only for going up stream; each train that it towed consisted generally of two or three fully laden barges, and the speed was about one mile per hour. But it could not compete with the horse towage service of the Deûle Canal, and was finally abandoned.

At the present time some experiments are being made upon the Bourgogne Canal with a small electric traction-engine, which runs on the towing path without rails; but in view of the failure which has always attended this method of haulage, the author thinks it will never get beyond the experimental stage, notwithstanding that it has been stated to be satisfactory thus far.

From the consideration of these four different methods of traction the author is of opinion that the only plan suitable for English canals, which are usually both shallow and narrow, is propulsion by means of screws, driven either by steam or by electric or oil motors. Haulage on a sunken chain or wire rope is quite inapplicable to the winding course of English canals; and on the Continent it is only upon long straight reaches with frequent tunnels, or where strong opposing currents are encountered, that it proves a commercial success.

Cost of Traction.—On the all-important question of cost, some plans which may be better from a mechanical point of view may be ruled out of court; while others not so good mechanically, but cheaper, succeed owing to their cheapness.

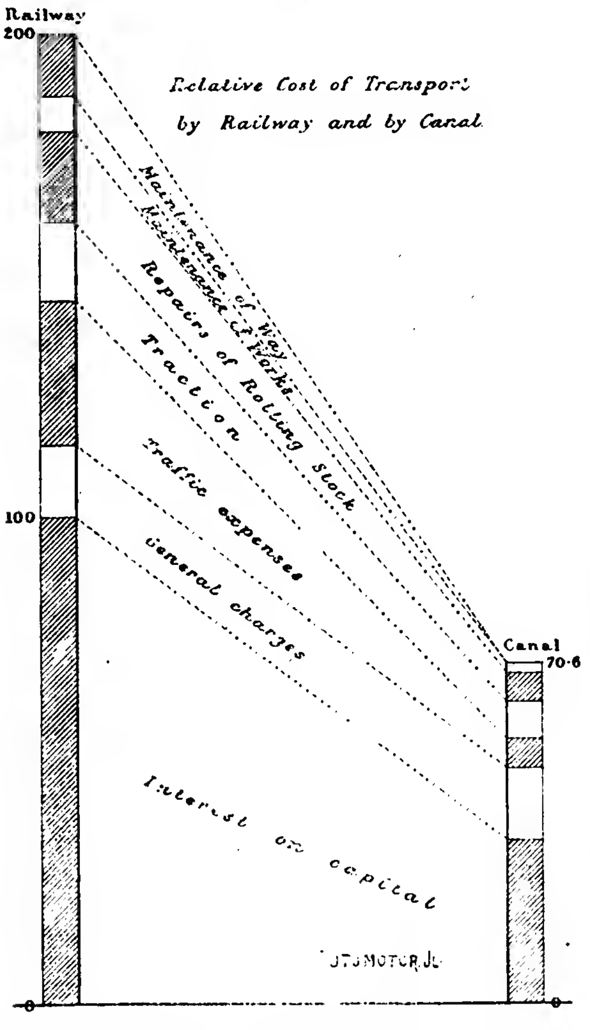
The cost of traction varies on every canal, and is dependent upon the regularity of the traffic, the freedom from locks, and other conditions. A method of mechanical propulsion which is remunerative on one canal might not be able to compete with horse traction on another. As an example: with the boat trains introduced upon the Aire and Calder Navigation by Mr. Bartholomew the cost of traction is about the lowest that has been reached, namely, 0·034*d.* per ton-mile; but, as he stated before the Select Committee on Canals in 1883, on a navigation like that of the Leeds and Liverpool Canal the same plan would cost 0·3*d.* per ton-mile, that is to say, ten times as much.

It is rather difficult to arrive at an exact basis of comparison for the cost of traction upon foreign and upon English canals, because most of the Continental inland navigations are State-aided, and in some cases the cost of maintenance is borne entirely by the Government, to the extent even of carrying the traffic at a loss; and therefore the cost per ton-mile includes merely the actual cost of the haulage and whatever tolls the Government may think best to put upon the canal, independently of whether it is paying or not. Whereas on our English canals the tolls have to be sufficient to ensure payment of interest, cost of maintenance, &c. In 1866 the

* Excerpt of paper read by Mr. LESLIE ROBINSON at the Institution of Mechanical Engineers.

cost of haulage by steam upon the Gloucester and Berkeley Canal was 0·077*d.* per ton-mile, while upon the Grand Junction Canal it was 0·166*d.* The difference may be traced directly to the difference in dimensions of the two canals; for while the Gloucester and Berkeley Canal is practically a ship canal, the Grand Junction is one of the shallowest in the country. According to the State Engineer's Report on the canals of New York State, the cost of traction upon the Erie Canal and Hudson River was as high as 0·238*d.* per ton-mile, including tolls. In his evidence before the Select Committee on Canals in 1883, the late F. R. Conder gave the cost of transport by steam traction on Belgian canals as 0·284*d.* per

PLATE 5.



ton-mile against 0·315*d.* by horse traction; these figures include tolls. The cost of traction by screw steamer towing three other boats on the Erie Canal was placed in 1892 by Mr. Bogart, an American engineer, at 0·082*d.* per ton-mile; the three boats towed each carry 250 tons of cargo, and the steamer carries 180 tons. By horses towing two boats the cost comes to 0·109*d.* per ton-mile. The speed with horses is 1·6 mile per hour, while with steamers it amounts to 2·5 miles per hour.

Considering the cheapness of transport by water, it would be remarkable that the English canals are not more extensively used, were it not for the fact that most of them are in the hands of the railway companies; or at least one or two of the junction canals which join important routes are so controlled, and upon these there are prohibitive rates in force, with the result that the traffic is kept down on the canals, and is nearly all monopolised by the railways. Even with the old mode of traction by horses it is found that minerals can be sent by canal considerably cheaper than by rail.

Time is, of course, an important factor for general traffic, but it is not of so much consequence for minerals, for which cheapness of transport is the first consideration. On the Continent the canals are the principal means employed for the conveyance of goods, and improvements are still being carried out in the way of widening and deepening their channels for facilitating the passage of boats; whereas in this country many of the canals are choked up with weeds, and have been allowed to fall into disrepair.

In support of the assertion that even with horse traction it has been found cheaper to carry minerals by canal than by rail, it may perhaps be well to quote some evidence. There are three principal causes which render transport by canal cheaper than by railway, and they are, briefly, the following:—First, on a canal there is no item of cost corresponding with the wear and tear of rails, sleepers, or fittings, though the cost of maintaining banks and locks must be taken into account. Second, there is a corresponding saving of the repairs required by rolling stock and locomotives in consequence of their running on a rigid permanent way. Third, the most important reason is that the maintenance of works on a canal is much less costly on an average than the corresponding outlay upon a railway, not only from the absence of vibration, but also from the much smaller magnitude of the works themselves. In his evidence before the Select Committee on Canals, Mr. Conder gives the accompanying Table 8, compiled from information at his disposal, and plotted

TABLE 8.—*Relative Cost of Transport by Railway and by Canal. See Plate* 5.

Items of Cost.	Railway.	Canal.
Maintenance of way	13	0
Maintenance of works	7	2·3

Traction	16	8
Traffic expenses	30	6
General charges	15	15
Interest on capital...	100	33·3
Total	200	70·6

as a diagram in Plate 5, which shows the relative costs for an equal tonnage transported an equal distance by rail and by canal. It will be seen that the carriage of heavy goods by canal costs about one-third of that by railway.

In Table 9 is added a summary of the average cost per ton-mile of the different modes of traction on canals:—

TABLE 9.—*Average Cost of Different Modes of Traction on Canals.*

Forth and Clyde Canal	Tugs	0·143

Conclusions.—The reason why the cost of transporting goods by canal is so much cheaper than by railway lies largely in the cost of construction. Taking the average cost of the Manchester, Sheffield, and Lincolnshire and the Lancashire and Yorkshire Railways, which was £65,700 per mile, and the cost of the Birmingham Canal, which was £15,000 per mile, the former is more than four times the latter; and the cost of maintenance will be proportionately greater for the railways. In view of the smaller initial outlay on canals, and the cheapness of mechanical traction thereon as compared with horse traction, it may well be asked, why has mechanical traction upon canals in this country not come more to the front? The answer is, not that mechanical engineers are unable to design machinery to do the work cheaply and expeditiously, but that the main difficulty arises from vested interests. The all-powerful railways have by some means or other obtained the control over a portion and even in some cases over a whole network of canals. Their control over even only one section of a canal means that they control the canal throughout its entire length, together with the branches opening into it. On many canals this leads to their falling into disrepair, or to certain portions being blocked, thereby effectually preventing any through traffic. Owners who would gladly have sent large quantities of goods by canal, and would thereby have opened up a remunerative field for mechanical propulsion, have reluctantly been forced to send their goods by the quicker but more expensive railway route. Continental canals on the other hand are controlled by the government, who in the interests of the whole community at large, foster this method of cheap transit; and this is the main reason why mechanical propulsion on canals is more widely developed on the Continent than in our own country. The cause of the non-success of mechanical propulsion in this country may clearly be considered to be beyond the forces which can be controlled by mechanical engineers.

The best method of mechanical propulsion for our own country, on canals which are still in the hands of private owners, must undoubtedly be that which necessitates the least alteration to the existing boats and canals in their present conditions, so as to be applicable to the boats in their present form, without structural alterations, and without in any way preventing them from passing through existing locks. The machinery should occupy as little weight and space as possible, and should be of simple construction and capable of being managed by an ordinary bargeman; the cost of first outlay and of maintenance must be small; and last but not least, the cost of traction per ton-mile must be as low as possible. As to the best form of boat to be used on any canal, and its relation to the wetted section of the canal, the author hopes that, as soon as the experiments of M. de Mas on this subject are published, the mathematical and theoretical side of the problem will be satisfactorily settled.

Mechanical Features of Electric Traction.*

Introductory.—Previous to discussing certain special mechanical features which enter into the design and construction of an electric traction system, a few figures may be quoted for showing the importance of the subject in general.

TABLE 1.—*Mileage of Tramways in America, and number of Cars, during Six Years,* 1890–95.

Table 1 shows the mileage of tramways in America for the six years 1890–5. It is seen that rope traction continued to extend up to 1894; since that time its importance has diminished. In San Francisco, Los Angeles, Minneapolis, Denver, St. Louis, Pittsburgh, Philadelphia, Baltimore, and other American cities, electric traction has been substituted in place of ropes.

Table 2 gives the electric tramway mileage in Europe at the end of last year, 1896. It will be seen that Great Britain is yet much behind Germany. This is especially remarkable, because the regulations of German local authorities are generally much the more severe. Electric trolley roads are now to be found in the oldest and handsomest of German cities.

TABLE 2.—*Mileage of Electric Tramways in Europe, and number of Cars, and Horse-power, at end of* 1896.

Russia	30	87	1,150
Other countries	30	50	111

Table 3 shows the great financial importance of tramways as compared with railways in America. The passenger traffic on the tramways is six times greater than that on the railways: and the ratio of working expenses to receipts is lower for the tramways than for the railways. The gross earnings of the tramways in the United States are approximately 50 per cent. of the passenger earnings of the railways, and 15 per cent. of the total earnings of the railways, whereas the tramway mileage is only about 6 per cent. of the railway mileage. A highly important fact is that tramway receipts are

* Paper read at the Institution of Mechanical Engineers by Mr. PHILIP DAWSON.

found to be practically independent of good or bad trade, and not to depend on the prosperity of the country.

Tables 4, 5, and 6 have been compiled from the official reports of the Massachusetts Board of Railroad Commissioners. Massachusetts more closely resembles England in the habits of the people and in local conditions than any other State of the Union. Table 6 shows the rapid increase of passenger traffic and mileage. Table 4 shows the difference in cost of completely equipping tramways in small and large towns, varying from £7,000 to £20,000 per mile of single line. Table 5 shows that as passenger carriers tramways play a much more important part than railways. It is demonstrated, not only in America but also in England and on the Continent, that wherever an electric tramway runs parallel to a railway the former will secure practically all local traffic. It has been frequently urged that mechanical motive power on tramways is dangerous to the public safety. In America, where comparatively high speeds are allowed, the Railroad Commissioners report that the proportion of passengers and employés killed during the last two years of electric working appears to have been about the same as with the use of horse-power in 1883.

For all practical purposes the present subject may be considered under the three headings of outside work, rolling stock, and power station.

Outside Work—Wires.—The overhead line of conductors may be supported either by brackets attached to poles or to houses, or by a span-wire stretched between poles or rosettes fixed to house-fronts. For the sake both of appearances and of smooth running the conducting wire should be strained as tight as is consistent with its tensile strength and with the minimum temperature which obtains in the locality. The best practice does not allow more than 2,000 lbs. strain on a No. 0 Brown and Sharpe (0·325 inch diameter) hard-drawn copper wire at the lowest temperature to which it will be exposed. With this limit the strain to be put on the wire when erected can be easily ascertained from tables. A rough but safe rule in this country, where rarely more than 20° F. of frost is to be expected, is a sag of 0·75 per cent. of the span at an average temperature of from 60° to 65°. The trolley wire should be of absolutely even quality, and supplied in lengths of slightly over half a mile. The joints should be silver-brazed in the copper ingot before it is rolled. The diameter of the wire should not be allowed to vary more than 0·0004 inch. The breaking strain of the wire should be at the rate of 56,000 lbs. or 25 tons per square inch. In span-wire construction it is necessary to determine both the height of the eye-bolts from which the span-wire is suspended, and also the sag. In Table 7 are given data of galvanised steel span-wires generally used.

Poles.—Upon the amount of sag allowed for the span-wires depends the strain which the side poles must stand. Round curves these strains are often great, and tubular poles composed of ordinary pipes wedged together by liners are useless. In Table 8 are given certain data of standard poles specially designed for this work. All poles must be of such strength that when in position they will stand without permanent set the greatest side strains to which they may be subjected. Terminal poles and pull-off poles on curves should be the strongest. Ordinary side poles must stand a direct strain of at least 500 lbs. without deflecting more than 4 to 6 inches. Their strength must be sufficient to carry, besides the trolley wire itself, the additional weight when the wires are covered with ice and snow. The poles are always subject to vibration communicated from the trolley wire. It is of the utmost importance that joints should be well constructed: which renders it necessary that the several lengths of the pole should be sweated together. The joint is made by heating the outside pipe to a welding heat, slipping it over the inner pipe, and then passing the two together through special rollers. After completion, if a piece is cut from the joint of the two pipes they will be found solidly welded together, the joining line having entirely disappeared. This is known as the "S S S" joint, the abbreviation meaning solid, swaged, and sweated. The tubes used in making poles are all lap-welded, and the larger sizes are also riveted along the seam with countersunk rivets. The lengths of pipe are so put together that the seams of each consecutive length are 120° apart, when the poles are made in three lengths, as is generally the case. If joints are not so made the pole, instead of bending uniformly, after a short time gives at the joints. Poles constructed with S S S joints can be accurately calculated to stand any determined strain without exceeding a fixed temporary and permanent deflection. This is not possible with other joints, which always give trouble sooner or later.

For the standard poles used at Bristol and Dublin five sizes are required, all 31 feet long, and set in the ground to a depth of 6 feet. No. 1 has to stand a lateral strain of 350 lbs. applied at top, with maximum temporary deflection of 6 inches, and a strain of 700 lbs. with maximum permanent deflection of $\frac{1}{2}$ inch. For the four others the corresponding limits are:—

No. 1 ..	350 lbs. with 6 inches, and	700 lbs. with $\frac{1}{2}$ inch.		
No. 2 ..	500 ,, ,,	,, 1,000	,,	,,
No. 3 ..	700 ,, ,,	,, 1,200	,,	,,
No. 4 ..	1,000 ,, ,,	,, 1,700	,,	,,
No. 5 ..	2,000 ,, ,,	,, 2,600	,,	,,

The poles are required to be as nearly round as possible. A difference of $\frac{1}{4}$ inch between maximum and minimum diameter is all that is allowed. In order that they may all be as nearly uniform as possible, $\frac{1}{16}$ inch more or less than the prescribed dimensions is all that is allowed. The greatest distance out of the true that is allowed at the top of the pole is $\frac{1}{4}$ inch. Ten per cent. of each lot of poles are tested; should three poles fail to come up to the requirements, the right is reserved to reject the entire lot. The poles are dropped three times, butt foremost, from a height of 6 feet upon some solid substance, after which they must show no signs of telescoping or loosening in the joints.

Insulators.—Insulators must be mechanically strong, and the insulation protected by a metallic covering from external injury. Special insulators have been designed for every variety of service, samples of which were exhibited. For ordinary tramway service the wire is usually soldered into the gunmetal ears of the insulators; but the heavy "figure 8" wire, used for light railways and high-speed lines, is supported by mechanical clips. Occasionally an extra heavy round wire is used, which is then milled out by a portable tool at the points of support, in order to afford a proper grip for the mechanical cars.

Rolling Stock.—This can be subdivided into car-bodies, trucks, motors, and their accessories. The bodies possess no special features, except that all framing must be extra strong.

Trucks.—The supply of suitable trucks for both motor and trailer cars is of the utmost importance. The introduction of electric traction has revolutionised the construction of running gear. In former days, when horses and mules were the only motive power for street cars, it was considered quite sufficient to support the car body upon a single set of springs carried by the boxes, a simple bar being often the only connection between the two sets of wheels. The adoption of the electric power and of cars equipped with single or double motors added immensely to the weight carried by the axles, and rendered it necessary to adopt efficient methods for cushioning and suspending the motors over the axles, while maintaining a rigid connection between motor and axle. At first the motors were rigidly attached to the bottom of the floor of the car body. This construction did not prove a success, for both car floor and motor deteriorated rapidly, and access to the motors was also difficult.

(To be continued.)

NEW INVENTIONS.

Claiming particularly to apply directly or indirectly to Motor Vehicles, &c.

Specifications Published.

7,858. Bicycles or Vehicles Propelled by Oil, &c. Anthony George New, Palace Chambers, Westminster. April 14th, 1896.

The object of the present invention is to enable motor-cars to be constructed in a lighter manner than has hitherto been accomplished, whilst retaining all the advantages caused by a heavy machine with regard to momentum.

A represents the axle, whilst B, B, are two fly-wheels rigidly mounted thereon and connected by intermediate gear, C, C, to the driving wheel, D, of the cycle. The fly wheels, B, carry crank pins, B 1, to which the connecting rods of the explosion cylinders are coupled in the usual manner. The intermediate gear, C, C, may be arranged to suit various requirements; for example, as shown, when one of the straps, F, is tightened around the internally toothed drum, G, the cog, H, will cause the pinion, I, to be carried round at a slower speed than the axle, A, and when G 1 is held stationary the internal toothed wheel, Q, will cause the pinion, N, to travel around the cog-wheel, M, keyed on the boss of G 1. As the pinion, N, is mounted within the hub, D 3, the road-wheel, D, will thereby be caused to rotate.

To obtain a slower speed the drum, G 2, is held fast, and the train of gears, H, I, J, K, gearing with the internal teeth thereof, causes the road-wheel to rotate accordingly, the wheel, K, being mounted on the hub of the wheel, D, in a similar manner to N, before described.

To reverse the direction of rotation of the road-wheel the drum, G 3, is held by its straps, F, and two or more sets of pinions similar to N and O are mounted on rotating arms. These arms can be connected to the road-wheel in any suitable manner in order that it will rotate in the same direction as the said arms. The wheels, N and O, in this case being rotated around the shaft, A, A cog M is keyed on the tube, W, which also carries the pinion, I, cog M, cog J, and internally toothed wheel, Q, and also provides a bearing for other parts of the mechanism.

A driving wheel so constructed as to enclose a fly wheel within its walls is also described.

5,430. Hydraulic Steering Gear. Ernest John Clubbe and Alfred William Southey, 16, Elm Street, Gray's Inn Road, Middlesex. March 10th, 1896.

This invention relates to improvements in steering locomotive road carriages in which hydraulic pressure is used as the medium of transmitting power from the motor to the driving wheels.

The hydraulic engine comprises two double acting cylinders mounted on the main frame and whose piston rods are coupled to the axle by links, the two pistons acting together as one and moving in opposite directions, the opposite ends of the cylinders being coupled by pipes, so that the admission of water under pressure from the pump of the circulation system to the front end of the one cylinder and to the back end of the other cylinder and the exhaust of the water from the other ends of those cylinders and the locking of the water in both ends of both cylinders may be controlled by a balanced valve. This valve is of the piston type and its cylinder is connected with the said pipes, whilst other pipes are respectively connected to the pump delivery and admission. The position of the piston valve in its cylinder is controlled by a hand-operated circular cam concentric with the king-bolt and movable about it as a centre, this cam being engaged by the forked end of a lever turning with the swivelling under-carriage and connected to the valve rod. In order that the fluid may be locked in the cylinder to hold the piston immovable at the required position, the cam plate is formed of equal segments in different planes connected by a short inclined segment intermediate of the segments. The middle part of this intermediate segment corresponds to the position of the valve at which the water is locked in both ends of the cylinders, and the operation is such that by moving the cam through an arc of any required number of degrees, the pressure is admitted to opposite ends of the two cylinders and the swivelling under-carriage is turned about the king-bolt through an arc of corresponding extent, the swivelling motion ceasing when by the lever reaching the middle of the intermediate part of the cam the valve is moved to such position that the water is locked in the cylinders.

The steering wheels are mounted on short axles pivoted on vertical axes in the forked ends of the main axle tree, which would in practice generally require to be pivoted to swivel about a main king-bolt at the wheel, axles being formed by the short arms of elbow levers whose long arms are coupled by links to the opposite ends of a piston rod which extends through the opposite ends of the hydraulic cylinder mounted on the swivelling under-carriage (if any) so as to be always parallel to the axle tree in order that by the motion of the piston in its cylinder the levers will be moved about their fulcrums. The long arms of the said levers are, however, curved towards each other or otherwise formed so that the distance between their ends coupled to the piston rod is so much less than that between their fulcrums, that the steering wheels will be swivelled to slightly different extents, so that the wheels will run in approximately concentric curves. The two ends of the cylinder are connected by flexible pipes with the cylinder of the balanced piston valve whose cylinder is connected by flexible pipes with the delivery and admission of the pump working the hydraulic power transmission systems, the valve cylinder being mounted on a bar capable of sliding in guides on the under-carriage, said bar being coupled by links to the long arms of the wheel axle elbow levers.

5,393. Generation of Motive Power. Carlo Gnattari, 70, Milkwood Road, Herne Hill, S.E., and The Guattari Power Syndicate, Limited, 16, St. Helen's Place, London. March 10th, 1896.

This invention relates to an improved method of generating motive power from carbonic acid gas in combination with reagents, whereby the pressure required for motive purposes is generated in such a way that the objections incidental to the use of carbonic acid gas in the compressed or liquid form do not arise, the gas being, moreover, used over and over again repeatedly.

The carbonic acid gas is generated in the usual way at atmospheric pressure, washed, passed through alcohol, and supplied to a reservoir containing water, alcohol, and hydrochloric acid, wherein it becomes absorbed or dissolved. The liquid holding the gas in solution is pumped into a boiler fired in the usual way and provided with a sight-feed device through which Dutch liquid (ethene chloride) is supplied in regulated quantities to the boiler. By the reaction of the carbonic acid solution and of the Dutch liquid under heat a mixture of steam and gases at high pressure is flashed out, which is then passed through a reducing valve to the engine cylinders. The engine exhausts into a coil or other form of surface condenser which is cooled by a solution of ether and chloroform in water into which carbonic acid gas is injected from time to time whereby a refrigerating effect is produced corresponding to from −90° C. to −100° C. the condensed product being returned to the main reservoir for use over again in the boiler

11,341. Steering Mechanism of Motor Road Vehicles. Camille Alphonse Faure, 37, Avenue de la République, Paris. May 23rd, 1896.

The steering wheels are pivoted and constructed, or arranged in such a way as to reduce to a minimum the force necessary to turn them on the road, they being mounted and operated so that they are turned on the central bearing point of their periphery. They are each pivoted on a pin fixed to the end of the axle, a disc being mounted on the said pin, this disc being received in the hub of the wheel. The periphery of the disc and the interior of the hub preferably have corresponding grooves, and anti-friction balls mounted in the said grooves, so as to constitute ball bearings between the disc and hub. It is preferred to convey the steering motion to the said wheels by means of arms secured to the discs and connected by rods and levers to a pedal, or other operating device.

14,212. Explosion-engines. Charles Frederick Wood, 35, Hanby Terrace, Ordnance Road, Enfield Lock, Middlesex. June 26th, 1896.

This invention relates to improvements in explosion-engines, and more particularly has reference to that class of engines in which explosive charges of air and oil or gas are employed.

The cylinder is open at one end and closed at the other, and is fitted with sliding piston whose rod is coupled with a crank. The cylinder may be provided at its open end with a slotted extension piece, which engages with the crank pin, the slot being sufficiently long to allow the crank to perform its revolution freely and impart to the cylinder its oscillatory motion. The crank pin may be provided with a wearing block which is capable of sliding within the aforesaid slotted extension.

The said hollow piston may be provided with end covers, the outer one of which may be made removable and he formed with an eye for connecting the said piston to the pivot pin on the framing.

An electric sparking device may be employed for assisting in the vaporisation of the oil.

The exhaust is effected through a valve in the cylinder near its closed end, the said valve being opened by mechanical means as hereinafter explained. The oil or explosive mixture is admitted to the cylinder from the hollow piston through a valve in the piston end opening into the cylinder, the said valve being held in its closed position by means of a spring. The valve opens automatically by reason of the partial vacuum formed within the cylinder at each alternate outward stroke of the piston; thus the oil or explosive mixture passes from the hollow piston through this valve into the cylinder. Whilst this is taking place, a valve or valves on the outer end of the said piston open inward automatically, thereby letting in a fresh supply of oil or explosive mixture for the succeeding charge.

The aforesaid hollow piston may in some cases be used as a reservoir for the oil, which may be fed into the cylinder through a valve arranged at the piston end, and the supply of air to the cylinder may be drawn in at a point above the surface of the fluid, a partition being provided with an outlet or opening therein to allow the gas to ascend. By these means any gas arising from the oil is drawn with the air into the cylinder. The hollow piston may be utilised for both purposes at the same time, that is to say, one portion thereof may be used as a reservoir for the oil, and the remainder as a gas chamber.

For the purpose of firing the charge, two pairs of electrodes are employed, one in each pair being movable and the other rigid. One is arranged in the cylinder and the other upon the end of the hollow piston in such a manner that the two make contact just at the finish of the inward stroke, and break contact to produce the sparks at the commencement of the outward stroke of the piston, thus igniting the charge and driving the piston outward.

The second pair of electrodes is arranged in the hollow piston, and preferably at the rear end thereof. One electrode is rigid whilst the other is movable through a stuffing-box (or other device) to enable contact between the electrodes to be made and broken. Electric sparks are thus produced. The movable electrode may be actuated in any suitable manner; for instance, by coming against the reciprocating piston or cylinder. Contact between the electrodes may be broken by the same means or by a spring surrounding the movable electrode. The sparking of both pairs of electrodes may be effected at the same time, or not, as desired.

9,199. Valves and Valve Gear of Gas or Internal Combustion Motor Engines. George McGhee, Mountblue Engineering Works, Mountblue, Glasgow. May 1st, 1896.

This invention relates to improvements in gas motor engines having motor cylinders working on the four-stroke cycle, and the object of my improvements are to simplify the valve gear and make the engine silent and more efficient in action by dispensing with tapped or clack valves and using piston valves in series.

According to this invention as applied to an engine having two or more sets of double cylinders mounted tandem together, there may be one valve case comprising the inlet for two cylinders and also the exhaust for another two motor cylinders, in which said case are two inlets, two ignition and two exhaust ports controlled by piston valves. Another valve case similarly organised serves as the exhaust and inlet respectively for the aforesaid two sets of double cylinders thus two valve cases serving four motor cylinders, the valve rods being reciprocated from a transverse valve shaft driven by two to one gear. Each said valve case would have located near its centre one air or motor mixture supply inlet port, on both sides of which is a motor cylinder inlet port, each controlled by a set of two piston valves on valve-rod. Again, nearer each end of the case is located a motor cylinder exhaust port, one for each of the other two motor cylinders, which with another exhaust port near each of both ends of case is controlled by its respective valve on both ends of valve-rod or spindle. The ignition ports may be located near the exhaust ports and controlled by exhaust valves.

In lieu of foregoing there may be two valve cases to each cylinder, one case for motor mixture inlet, and the other case for exhaust, each said valve cases having respectively an inlet or exhaust port controlled by a piston valve and a cylinder port. The ignition port may be arranged on either valve case, but preferably on mixture inlet case. Modifications for vertical engines are described.

THE following is a List of Specifications recently published, and obtainable at the Patent Office, 25, Southampton Buildings, London, W.C., at the uniform charge of 8*d*. per copy. Owing to the enormous pressure upon our columns it has been found impossible to deal in any other form with the accumulation of patents now being taken out in connection with automobilism. As far as possible, a selection for special mention is made by the Editor from the more prominent inventions:—

CONTENTS.

THE DIESEL OIL-MOTOR.

EVER since the days of Watt the efforts of engineers have been directed to improving the efficiency of the motor, whether this was actuated by steam or gas. It cannot be said that the improvement effected has been great. Certainly, in design, material, &c., modern steam and gas motors leave little to be desired, but the fact remains that in the most modern and very best steam motors the heat efficiency is but some 13 per cent., and this drops as low as 5 per cent. in small condensing steam plants. In gas or oil engines the efficiency may be as high as 25 per cent., but more often it does not exceed 17 per cent. There is thus plenty of room for improvement; but even supposing that a maximum could be obtained in practice, not more than 30 per cent. of the heat given to a steam-engine could theoretically be turned into work.

Steam, contrary to the ideas which generally obtain, is a very indifferent source of power. In generating it in the boiler there is a loss of from 20 to 30 per cent.; its theoretical efficiency is low, while its nature is such that it condenses quickly with the slightest fall of temperature. Coal or oil gas are much superior to steam as sources of power, but hitherto, owing to the methods of combustion employed, it has not been possible to obtain very satisfactory results. To Dr. Otto belongs the credit of having perfected the accepted type of gas-engine, while to Herr Daimler belongs the credit of having adapted this motor for automobile purposes, and another German—Herr Diesel—enjoys the proud distinction of having effected the greatest improvement in the efficiency of heat motors since these were first invented. He has, in fact, obtained in his motor an efficiency three times that of the best steam-engine, and half as much again as that of the best gas-engine. The Diesel motor is a remarkable and unique instance of synthetic reasoning. Starting with—and this is where so many inventors and would-be improvers fail—an accurate knowledge of the physics, or perhaps we should say the thermodynamics, of his subject, he has turned his constructive reasoning into mechanical effect.

The Diesel motor has also merits which the ordinary gas or oil motor lacks. It, in short, comes nearer the ideal motor than any other. It has been exhaustively tested and examined by the greatest engineering authorities in France and Germany. One of our distinguished engineers, Mr. Bryan Donkin, M.I.C.E., has also examined it, and it is from an article contributed by him to our contemporary *The Engineer*, and also to one contributed by M. Hospitalier in *La Locomotion Automobile*, that we are indebted for the following particulars:—

New Theory of the Process of Combustion.—The chief points forming the groundwork of the new method, as proposed by Herr Diesel, are the following:—In every process of combustion a distinction must be carefully drawn between the temperature of ignition and the temperature of combustion. The first is practically constant, and depends only on the physical properties of the combustible. The higher the pressure, the lower this temperature of ignition. The temperature of combustion, on the other hand, is variable—always much higher than that of ignition, and depends on many conditions, but chiefly on the quantity of air supplied. Hitherto the temperature of combustion has been produced after ignition, by and during the process of combustion itself. Starting from theory, Herr Diesel has evolved a new method of what he calls "rational combustion," for which four conditions are essential:—

(1) The temperature of combustion should not be produced by and during combustion, but before and independently of it, entirely by the mechanical compression of air. This apparently contradictory idea, which involves a complete reversal of our present notions of combustion, is really grounded on the Carnot process.

(2) It is essential that the air be compressed adiabatically only, and not at first isothermally, as required by the perfect process. In this way it is possible to raise the air to the temperature of combustion by pressures much lower than those required in the perfect Carnot cycle—say, from 30 to 50 atmospheres only. It is by reason of this departure from the pure theoretical cycle, in which pressures of from 100 to 200 atmospheres, and more, are required, that it

becomes possible to carry out the method of combustion at all. An impossible is replaced by a practical working cycle.

(3) The air being thus already raised by adiabatic compression to the temperature of combustion, the combustible must be injected into it by degrees in such a way that the heat developed by gradual combustion is converted into work as it is produced, by reason of the corresponding expansion of the air and gases driving out the piston. If this be done, combustion will produce only a very slight, if any, rise in temperature.

(4) The fourth condition also contradicts our present theories. It has hitherto been held that the excess of air for combustion should be reduced within the smallest limits. With Herr Diesel's method, on the contrary, a large excess of air is required, but this surplus quantity is carefully regulated, and the amount previously determined for each kind of combustible.

Twelve Horse-Power Experimental Engine.—The vertical single-acting single-cylinder inverted engine first made resembled a gas-engine in construction and design. The piston was above, acting downward in the usual way through a connecting-rod on to the crank. An auxiliary, or valve-shaft, driven from the crank-shaft by means of conical wheels carried two cams opening respectively the oil and air valves, which were held on their seats by springs. The working circle in this and the succeeding engines is as follows:—

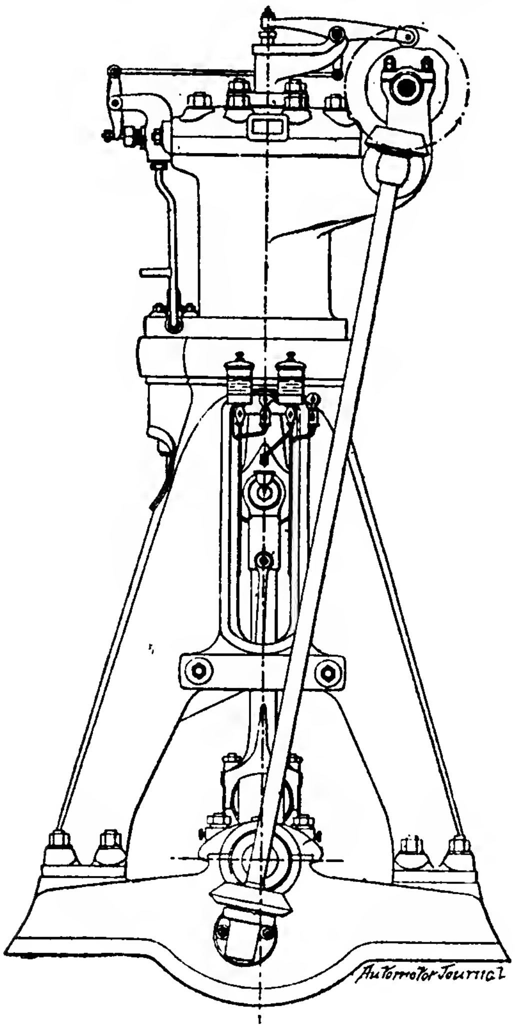

Fig. 1.

(1) The piston, driven down by the momentum of the fly-wheel, draws in atmospheric air through a valve at the top. (2) The piston rises, the air valve closes, and compression takes place till the air is at a sufficiently high pressure to attain the temperature necessary to produce combustion. Both temperature and pressure are regulated by the stroke of the piston, or the size of the clearance space. (3) Piston descends (motor stroke), oil admitted and injected into the air at high pressure from a small oil pump, the stroke of which is

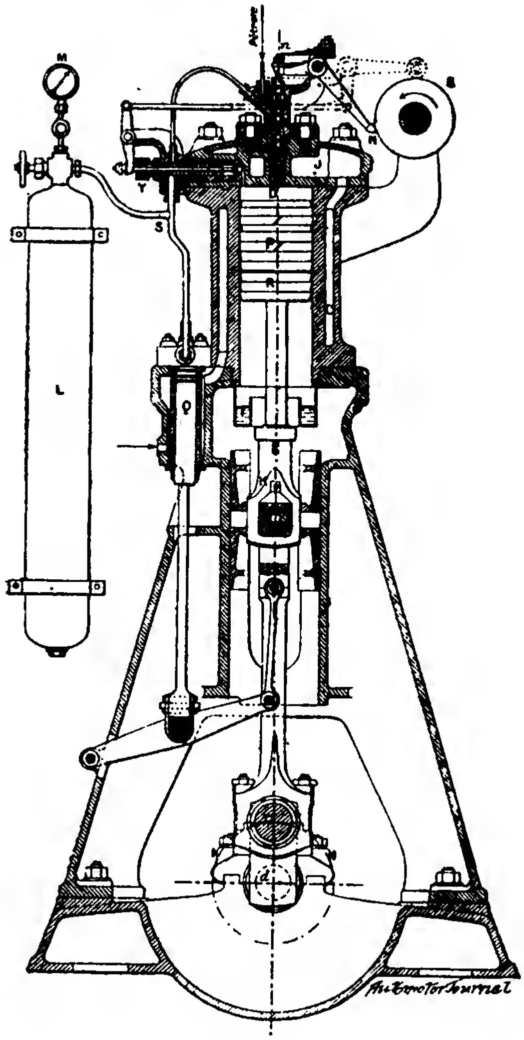

Fig. 2.

regulated by three different cams on the auxiliary shaft, giving a cut off at 2 per cent., 5 per cent., or 10 per cent. of the stroke. Thus gradual combustion is obtained after cut-off, and the air expands till the piston reaches the lower dead point. (4) Piston rises, exhaust valve opens, and air and gases of combustion are discharged to atmosphere; the cycle then recommences. The engine is started by connecting it to a receiver of compressed air, which is filled by the motor itself while running. There is no light, or ignition burner, and combustion is spontaneous.

Water Jacket.—The new motor was worked at first without a cooling jacket, but it was afterwards found desirable to add one. The water jacket is not, however, a necessary evil, as some think, but is required theoretically to carry off part of the heat, and in Herr Diesel's opinion all efforts to diminish greatly the losses of heat under this head are futile. There is only one right way, according to him, to secure this object, namely, to choose such a process of combustion that more heat than at present is absorbed in doing work; then, even on theoretical grounds, there will be less to carry off. As the new method required high pressures, temperatures, and speeds, the lines of existing engines could not serve as models, and almost every detail was the result of long and patient study, extending over two years. At the end of that time a second engine of the same size, embodying various improvements, was constructed, which, although far from perfect, gave surprisingly good results, and ran for months with oil and with lighting gas, to furnish power for part of the Augsburg Maschinen-Fabrik. As the result of these different trials, a new 20 H.P. petroleum engine was made, and tests on it were begun in the early part of 1897.

Twenty Horse-Power Experimental Engine.—This latest engine is shown in Figs. 1, 2, and 3. Fig. 1 is a general elevation; while Figs. 2 and 3 are sectional elevations; Fig. 4 is a plan of the cylinder head. As will be seen, it is vertical, inverted, single cylinder, single acting, and similar in external construction to an ordinary oil-motor. C is the cylinder. The piston, P, acts downwards through connecting-rod, *b*, on to the crank, c, below. The valve-shaft, W, driven by bevel wheels from the crank-shaft, carries several cams opening

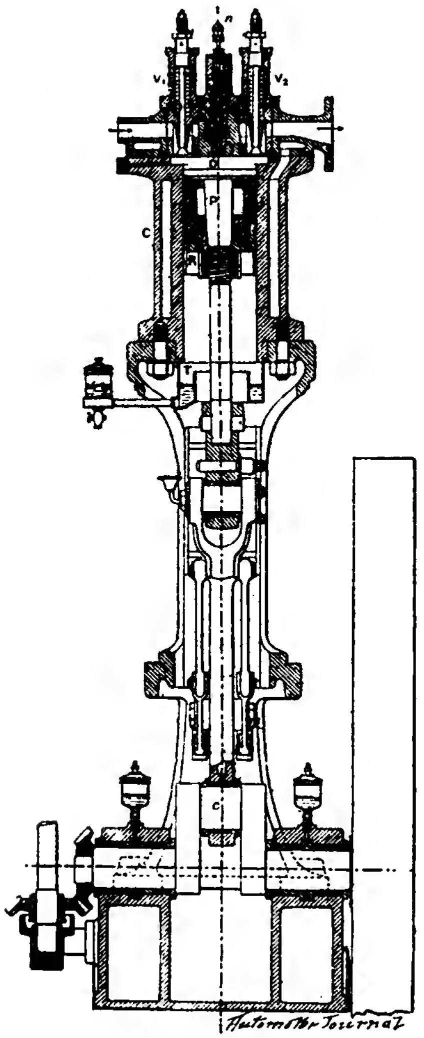

Fig. 3.

respectively the oil valve, *n*, the air valve, V_1, and the exhaust valve, V_2—Fig. 3. Another cam works the valve, V, for starting. A small vertical air pump, Q, also water-jacketed, and driven from the connecting rod by levers, X and *z*, forces air under pressure into the receiver, L, at the left hand side of Fig. 2. By means of the branch pipe, S, from L, the same pressure, which is much above that in the motor cylinder, is maintained in the injection nozzle, D, to which the petroleum passes through the small central needle valve, *n*. By varying the pressure in the receiver, and the stroke of the air pump, the admission of oil can be accelerated or retarded, and the progress of combustion thus regulated.

Tests.—Experiments were made on this new 20 H.P. engine in February, 1897, by representatives of the Krupp, Sulzer, and Deutz firms, and by Professors Schröter, Gutermuth, Sauvage, and others. Most of the trials lasted several days, and the engine was put to the test in every possible way. These experiments confirm Herr Diesel's statement that the efficiency of his engine is higher than that of other motors. The boiler efficiency is equal to unity, there being none. The theoretical possible heat efficiency varies from 50 per cent. to 70 per cent., and is about twice as high as is possible in the best steam-engines, and half as much again as in internal combustion motors. This in part explains the superiority of the new engine, especially when made compound as described. The indicated efficiency, or the percentage of heat actually turned into indicated work, is 70 per cent. to 80 per cent. of the maximum theoretical possible efficiency, while the mechanical efficiency is 71 per cent. to 75 per cent. Perhaps one of the most important characteristics of the engine is its small dimensions, as compared with other explosion motors, being much less in size for the same speed and power. The mean available pressure is also higher, the area of work, as shown by the indicator diagrams, is larger, and hence the cylinder dimensions less. It was at first thought that the very high pressures of air would necessitate heavy connecting rods, levers, and crank-shaft, but it is now found that these can be lighter than usual.

The performance of the engine is regulated by the cut-off, that is, the period during which oil is admitted, and it responds quickly to the governor. No explosions are missed, and this is an advantage as compared with internal combustion motors, one of the chief drawbacks of which is their irregularity in running. The engine is always ready for work, and no dirt or grease collects on the internal surfaces, because combustion is complete. No arrangement for ignition, either electrical or by flame or hot tube, is required, nor is there any vaporiser or pulveriser. Unlike the steam-engine, it gives practically the same results, whether made large or small, and, therefore, no object is gained by centralising the power, nor need it all be supplied for

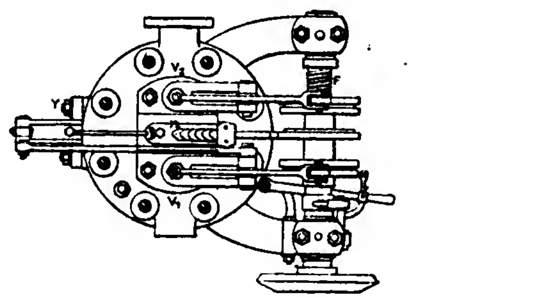

Fig. 4.

many purposes from one engine, with the consequent disadvantages of long and expensive shafting. Of course, the chief recommendation of the Diesel motor is its low consumption of oil, which is only ½ lb. per B.H.P. hour, under normal working conditions.

Experiments have already been made with petroleum and lighting gas, and the Augsburg Maschinen-Fabrik are testing the motor with ordinary hard coal, and are now constructing a 150 H.P. compound experimental engine, with generator for driving it with cheap or power gas. The oil trials made by Professors Schröter and Gutermuth showed a heat efficiency per I.H.P. of 34 per cent. to 35 per cent., or 50 per cent. more than is obtained in gas-engines when working at maximum power. Further, the engine is new, and capable of greater development. If power gas from a generator be used, there is of necessity a loss of heat in the generator, which only converts about 80 per cent. of the heat in the coal into gas; but improvements in this direction may be expected, especially if the gas be compressed to 40 or 60 atmospheres. The latest experiments with the 20-H.P. engine show a consumption of 0·47 lb. oil per B.H.P. hour. Herr Diesel's views are confirmed by Professor Schröter, who considers that the theoretical principles on which the engine is constructed have been justified by the result. In most new inventions engines have first been built and their theory deduced afterwards; with this engine the contrary course has been successfully followed.

Professor Schröter's Trials on a 20 H.P. Diesel Oil-Engine.—The engine constructed by the Maschinen Fabrik-Augsburg was tested by Professor Schröter under the following heads:—Indicated and brake H.P., consumption of petroleum, quantity of cooling jacket water, and heat imparted to it, and temperature of the exhaust gases. Arrangements were also made to determine the chemical composition of the exhaust gases and heating value and composition

N 3

of the petroleum, and the results checked in the Technische Hoch Schule at Munich. Both the motor cylinder, in which the ordinary four-cycle was carried out, and the single-acting air pump were indicated. The piston diameter in the motor cylinder was 9·8 inches and stroke 15·7 inches; diameter of the air-pump piston 2·7 inches, stroke 7·8 inches. The indicator springs were previously carefully tested, and the mean values obtained were taken. The scale adopted was 1 millimetre per atmosphere. The efficiency was assumed to be the difference in indicated work shown by the motor cylinder and air-pump indicator diagram. There were five trials in all, two at full, two at half-power, and a fifth while running empty. Each lasted one hour. Fig. 5 gives an indicator diagram taken during a full-power trial; Fig. 6 an indicator diagram from the air-pump or negative work. During the two experiments at full power the revolutions per minute were respectively 171 and 154: the governor was fixed during each trial, and no variations in speed were allowed. It was shifted for each fresh experiment. The mean pressure in the motor cylinder was 7·4 atmospheres, 108 lbs. per square inch;

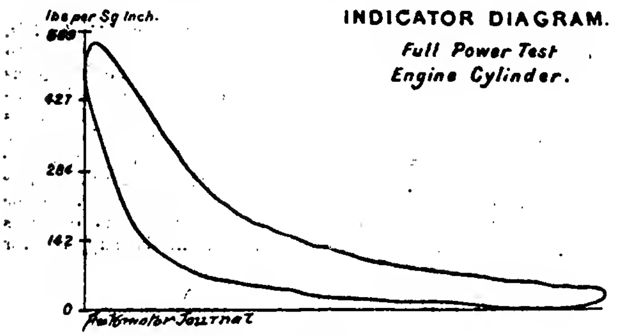

Fig. 5.

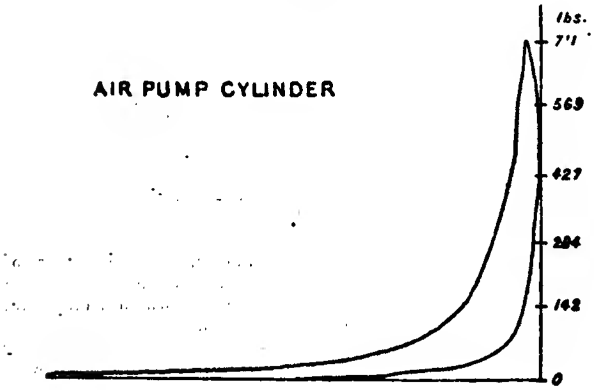

Fig. 6.

I.H.P. 26·5 and 23·6 respectively—deducting the air-pump I.H.P. This difference in power in the two cases was due to the different speeds. A brake was applied, and gave for the first trial 19·8 B.H.P., and for the second 17·8 B.H.P., or a mean mechanical efficiency of 75 per cent. Professor Schröter remarks that "all his co-workers were surprised at the simplicity of the engine, and the ease with which it was started," by connecting it to the receiver, where the pressure was always 40 atmospheres. He considers that "it ran so quietly and steadily that it was difficult for an outsider to realise the forces brought into play." No difficulty was found in preventing leakage from the receiver.

Consumption of Oil, Heat, Value, &c.—The petroleum was taken from a carefully-gauged can, duly weighed before and after each test, and the consumption found to be 0·54 lb. and 0·52 lb. per B.H.P. and 0·40 lb. and 0·39 lb. per I.H.P. per hour respectively for the two full-power trials. For the two trials at half-power, namely, at 9·5 B.H.P. and 9·8 B.H.P., the consumption was 0·61 lb. per B.H.P. hour. These figures show that even now, in its earlier experimental stage, the engine is ahead of other oil-motors, and while running at ordinary speed with normal full load gives a consumption in round numbers of ½ lb. oil per B.H.P. hour. It should be noted that the relatively increased consumption at half-power is only 15 per cent. The temperatures of the exhaust gases were taken behind the exhaust valve, those of the cooling water into and out of the jacket. The quantity of water was measured from time to time by observing the length of time required to fill a large tank, and the temperatures being simultaneously read off, the heat carried off in the cooling water jacket was thus approximately determined. The density of the petroleum used was repeatedly taken from both the feeding can and the supply tank, and was found to be about 0·80 when reduced to normal temperature. The mean composition of the oil was 85·13 per cent. C., 14·21 per cent. H., and 0·66 per cent. O.

Heat Balance (Full-Power Trials).

FORBES' LIQUID FUEL REGULATOR.

Sir Charles S. Forbes, Bart., of Castle Newe, Strathdon, Aberdeenshire, has recently patented a regulator for regulating the supply of liquid fuel to a furnace, which possesses some novel and interesting features. The apparatus is constructed as follows:—A cylinder formed from brass or other suitable metal is carefully bored and fitted at one end with a gland or stuffing box, and at the other with a screwed plug. A piston rod passes through a well fitting piston which occupies the lower part of cylinder and above the piston, and pressing upon it is a spiral spring, the upper end of which presses upon the screwed plug. The piston rod passes through the screwed plug at its upper end and is threaded and fitted with a milled headed nut, the lower end passes through a stuffing box and is fitted with a coupling. Ports are formed in the cylinder by means of screwed connecting pieces cast with it. One of the ports opens beneath the piston and is coupled by means of a union with the steam boiler, the other port is above the piston and serves to convey any steam that may leak past it to the chimney, or a condenser when employed. The foot of the cylinder is screwed, and to this is fitted a distance piece which serves to carry the oil cock.

This cock consists of a casting in which is a valve and an inlet and outlet port, one of these ports is connected by piping to the oil tank, or other supply, the other to the jet or burners. The valve is mounted upon a piston rod which passes through a stuffing box at either end, the lower end of this piston rod being screwed or threaded and fitted with an adjusting nut whereby the valve may be so regulated as to prevent the flow of oil to the burners being entirely stopped.

The upper end of piston rod is secured to the coupling of regulator. The *modus operandi* is as follows:—The combined regulator and cock being mounted up in any convenient position by means of a bracket, generally cast in one piece with the cylinder, connection is made with the steam boiler and the oil supply and burners. Steam now enters beneath the piston which is forced upwards against the spring, the tension of which is regulated by means of the screwed plug, until the piston remains stationary at the desired boiler pressure, and the valve in the cock admits sufficient oil to the burners. If now a less demand of steam is made on the boiler and the pressure rises the piston will force up the spring and diminish the oil supply. On the other hand, should the boiler pressure fall, the spring will force down the piston and admit a larger supply of oil to the burners. By means of the adjusting nut threaded on the spindle passing through the cock the valve is prevented when desired from entirely closing. In some cases the adjusting nut may be dispensed with, the regulation of the oil valve being effected by the coupling suitably modified.

Referring to the accompanying drawings, Fig. 1 is a part sectional view on line A B, Fig. 2; Fig. 2 is a plan; Fig. 3, modification of plan; Figs. 4 and 5, modification of oil valve adjustment; Fig. 6, modification of piston rod packing; Fig. 7, modification of jointing.

In the drawings, 1 is the cylinder which may be formed of brass or other suitable metal. This is carefully bored out and fitted at the top end witb a plug or stuffing box, 2, threaded as at 3, or it may be adjustably secured by studs or bolts and nuts, 4, *see* Fig. 3. Tbe base of tbe cylinder is fitted witb a screwed plug or gland, 2^a, in packed with rings, 11, as shown, is employed, serves by means of tbe nut, 12, threaded on the rod to securely hold the same. The piston rod after passing through the glands, 2, 2^a, is threaded into tbe adjusting wbeel or nut, 13, which is recessed as at 13^a, on its underside.

Forbes' Liquid Fuel Regulator.

which holes, 5, are drilled so as to enable it to be adjusted by means of a key. A piston-rod, 6, formed from any suitable metal, is turned, threaded as at 3, and pinned as at 7, to the coupling, 8. A shoulder, 9, is formed on the rod, and when the particular type of piston, 10, Surrounding tbe piston rod is a spring, 14, this spring presses upon the piston, 10, and the underside of stuffing box screwed plug or gland, 2, its tension being regulated by screwing the same up or down. Ports, 16, 15^a, are formed by means of the nose or connecting pieces, 16, screwed as at 3. The pipe conveying steam from the boiler is connected by a union or like means with the port, 15, which opens beneath the piston, any waste steam passing the piston being conveyed to the chimney or condenser when such is employed by the port, 15^a. The foot of cylinder, 1, is screwed as at 3, and by this means carries the distance piece, 17, the end of which is similarly threaded and supports the oil-cock, 18. This cock is usually cast from gunmetal or brass and has an inlet port, 15^b, and outlet port, 15^c, cored or formed in the branches which are threaded at their ends for connecting up the oil feed and discharge pipes. A valve, 19, is mounted on a turned spindle, 20, formed from some suitable metal, and is secured in position by the nut, 12. This spindle passes through the stuffing box, 2^1, and is secured by adjusting nuts, 12^1, to the coupling, 8. The lower end passes through the screwed cap, 21, and gland, 2^{11}, a lock-nut, 12^1, being threaded on the screw end of spindle, 20.

The regulating device may be attached to the boiler or elsewhere by flanged seating, 22.

The operation of the apparatus is as follows:—The ports, 15, 15^a, are connected by suitable piping with the boiler and condenser or chimney, the flow of steam to port, 15, being regulated by a cock. The ports, 15^b, 15^c, are connected to the oil tank and burners, a cock being placed between the oil tank and port, 15^b, to cut off the supply of oil when the apparatus is out of use. The spring, 14, is now regulated as nearly as possible to the boiler pressure by turning the adjustable screwed plug or gland, 2, until the maximum supply of oil required is attained, the adjusting wheel, 13, being then run down to the face of the gland to prevent this supply being exceeded. Should the boiler pressure increase the piston will be forced up and the supply of oil reduced or entirely stopped. Since, however, oil-burners tend to blow out in rough weather if the supply of oil be suddenly diminished the small regulating nut, 12^1, may be employed, by screwing this up the valve can be so regulated as never to cut off the supply of oil entirely.

Fig. 6 shows a modification of a piston which has given good results. The rings, 11, shown in Fig. 1, are dispensed with, and a cupleather, 11^a, employed. It is found that the water which collects beneath the leather suffices to effectually protect it from the direct action of the steam, moreover, it is more convenient for small-sized regulators and keeps steam tight with the minimum of friction.

Figs. 4 and 5 show in part elevation and section a modified form of adjustment which may in some cases replace that shown in Fig. 1. The upper end of spindle, 20, passes through the coupling, 8, which is formed with a milled edge, 23, and turns loose on the end of piston rod, 6, supported by the collar and pin, 24. It can be locked in any position by the nuts, 12.

Three claims are made. The number of the patent is 28,279, of 1896.

SOME DIFFICULTIES OF MOTOR-VEHICLE CONSTRUCTION.

(*Contributed.*)

THE introduction of a new principle or a new machine is always looked upon by different sections of the public with different degrees of interest, and when the adoption of such a new principle is at all likely to make any sweeping alteration in any particular method of our everyday life, the distrust with which it is met by the one section is not more intense than the enthusiasm with which it is hailed by the other. But as distrust and enthusiasm are both in a great measure the outcome of ignorance—distrust, through an underrating of the value of an invention or innovation, and enthusiasm through an overrating of it—it will be the policy of the wise man to steer a middle course, and to become acquainted with the difficulties connected with a new project, and how they are to be overcome, before coming to any decision as to its era-making probabilities.

To get some idea of these difficulties it is necessary to note the more general methods by which it is proposed to apply mechanical power to the propulsion of road-vehicles. Broadly speaking, there are three sources of power which may be employed, viz., electricity, steam, and gas. In view of the difficulties and disadvantages attending the use of electric energy and steam power, many engineers think that the most satisfactory solution of the problem of mechanical traction on roads is to be found in the use of oil or vapour as a source of power, and it is, therefore, to the difficulties to be found in the application of oil to the moving of road-vehicles that our attention will be directed.

The use of inflammable air for obtaining motion has been experimented with since the year 1791, when one of the first patents for gas or vapour engines was granted, and since that period the science of gas-engine construction has rapidly advanced.

Without going into the theory and practice of oil-engines, and the application of such engines to road-vehicles, it will be necessary to point out those problems and difficulties which it would seem are the most essential to solve and overcome, and which up to the present have been the most serious obstacles to the production of a perfect road-vehicle—that is, one which shall most satisfactorily fulfil the requirements of such a vehicle; and it will be well, before going further, to determine exactly what such requirements are.

The first essential of a motor-vehicle is that it shall be as simple as possible in construction, so that it may be handled by the inexperienced in mechanical matters easily and surely. It must be capable of exerting without any difficulty the maximum power which will be required in propelling it under the most adverse conditions of load, distance, speed, and nature of road which it will ever be likely to encounter. It must be easy to regulate, both as to power, speed, and direction, and such regulation must be accomplished with absolute precision.

Another condition, and one which is of the greatest importance if the motor-vehicle is to compete successfully with animal traction, is that the cost of energy and maintenance shall be as low as possible. Many of these requirements have already been fulfilled in vehicles at present in use, though not in an altogether satisfactory manner. An oil or gas engine, to give out the best results and to show a maximum of economy in working, must be run at a constant speed, or as nearly constant as possible. On the other hand, a road-vehicle must be capable of constantly changing its rate of speed; so that it becomes impracticable to directly couple an oil-engine on to a vehicle, and an intermediate system of gearing must be employed.

Another reason for this intermediate gearing between engine and work is that, although the vehicle must be constantly stopped and sometimes reversed, the motor must continue running, and that in one direction only. To start an oil-engine requires the application of manual power, which it would be inconvenient to apply at every stopping and starting of the vehicle. To reverse such an engine, even were reversing mechanism easily applied, would also involve stopping and the consequent manual effort of starting.

It is in the arrangement of the system of gearing that our first great difficulty lies. The problem of varying the speed of revolution of a shaft driven from another shaft running at a constant speed is one, however, which has not yet been solved in a way to make its application at all practical. In the application of such a mechanism to motor-cars it must be remembered that it is necessary to accomplish the change while running, and also in a manner which will give *any* speed, not one of three or four *fixed* speeds. This then is Problem No. 1. The arrangements at present in use for accomplishing this object are complicated; they generally involve excessive friction, in some cases seriously affecting the economical transmission of power between the engine and the vehicle driving-wheels. They are also in nearly all cases confined in their action to a series of three or four pre-determined speeds, and in that particular do not give to the vehicle on which they are applied that ready regulation which is essential in the crowded traffic of our streets.

The next difficulty arises from the governing of the engine. The governing of an oil-engine presents difficulties which are not found in the gas-engine, and these difficulties vary considerably with the various methods of vaporising the oil or spraying it. It is in engines in which the system of heating and spraying the oil in order to mix it with the air charge and so form an explosive mixture is employed that the difficulty of governing the engine is mostly felt. This is also the case in those engines in which the oil is injected into the cylinder and vaporised by the heat of the cylinder walls and enclosed hot air. In the first case the heated exhaust is used to heat the vaporiser, and if the plan used in the gas-engine were employed, that is of cutting off the supply and allowing no explosion to take place until the speed is reduced, the vaporiser would cool to such an extent as to stop its action altogether.

As at present arranged, governing is only effected by either reducing the oil supply or by cutting it off and keeping the hot exhaust in the cylinder and allowing it to be alternately compressed and expanded by the piston. In the first of these methods the economy is very little, the engine using nearly as much oil when running light as with full load. In the alternate method, the vaporiser, in spite of the imprisoned exhaust. rapidly loses heat, and the explosions will be unable to be resumed if the cut-off lasts for any length of time. In the second method, in which oil is injected into the cylinder and there vaporised, similar difficulties arise.

Yet another type of engine is the one in which the oil is vaporised in a vessel separate from the cylinder, and the difficulty of governing is not in this case so great, the ordinary method of governing as applied to gas-engines being generally employed with good results. But even such a method when compared with the governing of a steam-engine, with its beautiful system of cut-off and expansion, is crude and requires greatly improving upon. This, then, is Problem No. 2.

The next difficulty arises in the cooling of the engine cylinder; in engines using heavy compressions and high temperatures it is very necessary to keep all the working parts as cool as possible in order to prevent overheating of bearing and scoring of cylinders. This has been accomplished in many instances by casting numerous ribs of iron round the outside of the cylinder, giving a large surface for the radiation of heat from the cylinder. This plan is, however, not always effective, and where an engine is running constantly on heavy loads the working parts in this arrangement are likely to become considerably overheated.

Another method has been to cast a water jacket round the cylinder and use a water circulation from a tank, often taking it through the tubes of which the frames of the vehicle are constructed, and so getting a larger radiating surface.

Neither of these methods are altogether satisfactory. The first is open to the objection that in order to allow a free circulation of cool air to reach the extended ribs of the cylinder the engine must be exposed to dust, dirt, and weather. The latter method is objectionable on account of the weight of the circulation water, the necessity of constantly replacing it by cool water on long runs, and the great liability to leakage at the joints owing to the straining of the vehicle frame. It is also very liable to set up internal corrosion, and thus materially weaken the frame construction. Problem No. 3, therefore, is to devise some simple method of cooling the cylinder and working parts of the engine without more than is absolutely necessary increasing the weight or inconveniencing the attendant by want of constant attention.

The next difficulty arises in connection with the exhaust, which, unless restrained, is noisy, and gives off offensive smells. Various kinds of silencers have been devised, some attended with great success; but it is probable that in most cases they produce some back-pressure, which is to be avoided, and in all cases they fail to get rid of the smell. So that Problem No. 4 is to devise an efficient silencer, which shall produce no back-pressure on the engine, and shall at the same time, by condensation or otherwise, remove the odours of the burnt or partially-burnt gas.

These problems have been for a considerable time engaging the attention of engineers, and have in some few cases been partially overcome. But there still remains a great field for improvement, and they have only been pointed out with a view to showing the direction in which inventive labour must be turned, and as demonstrating to the uninitiated the difficulties which have yet to be overcome.

To judge the motor-vehicle by its present standard of perfection or imperfection would be obviously unfair: it can only be regarded as an indication of the progress which is being made. That so much has been accomplished is greatly to the credit of those who have the work in hand, and gives every encouragement to look forward to the ultimate perfection of this class of vehicle. That its introduction in a thoroughly practicable form will solve to a great extent the increasingly difficult problem of street traffic in large towns, by giving better control and limiting the ground space occupied by each vehicle in a crowded thoroughfare, must be universally acknowledged. That it will contribute in a great measure to the more healthy and sanitary condition of our streets is also apparent.

The substitution, however, will not take place in a day, but it is sure to come. The struggle between conservatism on the one hand, and radical improvement on the other, can have but one ultimate result, and as the stage-coach of years ago has been supplanted by the railway of to-day, so the horse-propelled vehicle of to-day must in the near future give way to the improved motor-vehicle; and the more rapidly the difficulties indicated are overcome, and the different problems satisfactorily solved, the sooner will the reform be completed.

BROWN'S OIL-FIRED STEAM AUTOMOTOR.

MR. W. H. BROWN, of Beechcroft, Devizes, sends us, in reply to our request, the following description and illustration of what seems to us to be an exceedingly well-designed and useful steam vehicle. He writes:—

"Referring to your favour to hand, I am pleased to give you what particulars I can that I think will be of interest to you. I should have been pleased to have sent you the working drawings, but I only have them complete as far as the engine and boiler go. The car body gearing and wheels were made from dimensioned hand sketches. The general arrangement of the car you can see by the photo. It is a four-wheeler, and steers with the front pair, which work in forks, with a spiral spring on the top. This arrangement I am going to alter and use the jointed-axle principle, as it is a much better and stiffer job and admits of better springs being used. The front wheels are 2 feet diameter and the back ones are 3 feet diameter, and are the drivers. The car body is like an ordinary governess car, capable of seating four comfortably, two each side—three might be crowded in.

"The advantages of this form of car are that the passengers are together and can talk, and the driver gets a good view in both directions; in fact, it is as easy to run backwards as forwards. This feature I have found most useful in narrow roads and lanes where there is not room to turn round.

"The engine is a double-cylindered one, with cylinders 2¼ inches in the bore and 3-inch stroke, and are geared four to one and ten to one respectively for the fast and slow speeds, and run about 400 revs. per minute for 12 miles an hour. It is fitted with an ordinary link motion for reversing. Under the engine is a 25-gallon tank, which is equal to 15 miles about on a fairly level road. I have a length of hose pipe and an ordinary steam water-lifter for filling the tank. The differential gear is on the intermediate shaft. The chains are Brampton's block chain, which gives every satisfaction in use. I have two band brakes on the driving-wheels. The boiler is an ordinary vertical one fired with petroleum, and is the only weak part in the whole machine. I have tried several burners without success, so eventually I tried coal, to see if it was the fault of the boiler or not. With coal I had difficulty in keeping the steam down.

"I am now making a new boiler with about 50 per cent. more heating surface, which I hope will give better results. I carry about four gallons of oil in the tank I am burning from, and have two two-gallon tins besides as a reserve, so I am not likely to get stalled for want of oil. Can you give me any particulars about oil firing, also the amount of oil which should be burned per I.H.P. per hour? From my experience a great deal more heating surface is necessary when using oil than when burning coal. Is this the usual case? I find I have plenty of power on my car; I have been up some very steep hills, and it has never shown any sign of stopping. I usually carry about 160 lbs. of steam per square inch in the boiler, but sometimes it rises while running downhill. The only way I have been able to keep steam when burning oil has been by reducing the speed of the car to about eight miles per hour, and of course that is nothing like fast enough. I have taken your valuable paper for some months now, and have just bought a copy of your POCKET-BOOK, which I find very useful.

"And now, Mr. Editor, I think I have told you everything; if not, I shall be pleased to answer any questions you may ask me. Wishing you and 'our sport' a prosperous new year,

"I am, yours faithfully,
"W. H. BROWN."

[We need hardly say that we are obliged for our correspondent's good opinion, and especially as this arises from the information we supply our readers. As regards oil firing we should say that the difficulty consists in effectively utilising the heating surface; this points to an insufficient volume of flame. Much depends upon the type and number of burners. A good deal of necessarily condensed information will be found in the AUTOMOTOR POCKET-BOOK, but it will be useful to consult "Hodgetts on Liquid Fuel" (Spon). As regards heating surface, the number of square feet per I.H.P. for vertical boilers is given with considerable accuracy by the formula—$H.S. = \frac{22}{\sqrt[3]{P}}$, where P is the boiler pressure. Some information on this head will be found in the paper recently read before the S.P.T.A. by the Editor, and which is reprinted in the present number. As a general rule, a liberal amount of heating surface should be provided in all cases.—ED.]

LES POIDS LOURDS.

Report of the Commission—III.

IN our last article we analysed the performances of the vehicles included in the first classification, viz., those of the Scotte, De Dion, and Panhard types, which are intended to act as passenger and goods omnibuses. We now proceed to discuss the qualifications of those vehicles which possess different characteristics from those before mentioned. Those are the De Dion et Bouton; Pauline, No. 13; the steam passenger train on the Scotte system, No. 3; and the petroleum automotor, or *camion*, by Dietrich and Co., No. 8.

We shall describe each fully, as in the previous articles. The first is the Pauline, of MM. De Dion et Bouton; this is a steam bogie motor, known officially as No. 13. We give an illustration of this vehicle on p. 169.

As will be seen, it really is an articulated six-wheeled bogie van, capable of carrying 35 passengers. On the level the speed attained is 8·7 miles per hour, and this is not sensibly reduced even on steep gradients. This vehicle costs 26,500 francs, of which the tractor costs 17,500 francs. This latter is fitted with boiler and mechanism of the usual De Dion type, the only difference being that these are larger, and, as before said, the motor gives off 35 H.P. The brake is not unlike similar vehicles much patronised by the London workingman or mechanic for "beanos" and other purposes. We hope sincerely to see ere long vehicles of the De Dion et Bouton type on the roads leading to Epping Forest, the Welsh Harp, Epsom, and other places of holiday resort. When we see such a vehicle steaming, say, through Oxford Street, and its approach heralded by the sweet strains of a cornet or concertina accompanied by the beery voices of the excursionists, giving a wholly gratuitous and not altogether desirable rendering of the latest music hall songs, we shall be able to say that automobilism has at length found a secure foothold in the hearts of the British public. At present we take our pleasure sadly in the familiar four-horse brake, driven invariably by a man who will persist in wearing a white hat—why, it is difficult to say.

To resume. The proportion of the "useful weight," *i.e.*, weight of cargo and for passengers to the dead weight in working order, *i.e.*, tractor-bogie and brake, is ·337, while the proportion of the "useful weight" to total weight is ·252.

The following are the general particulars:—

Length over all	21·32 feet.
Breadth „	6·56 „
Height of deck	4·92 „
Length of tractor	12·46 „

(No other particulars of weights, &c., are given.)

According to the constructors the consumption of coke and water for a speed of 8·7 miles per hour is—coke, 14·2 lbs. per mile, or 3·3 lbs. per H.P. hour; water, 57 pints = 7·12 gallons per mile, or 12·3 pints = 1·54 gallons per H.P. hour. The quantity of coke and water carried suffices for a run of 16 miles.

It may be mentioned that while making Journey C during the trials the low-pressure cylinder fractured, and the remaining portion of the journey was accomplished with the high-pressure cylinder.

The following is the cost of working, &c.:—

Price of vehicle, 26,500 francs.

	Francs.
Interest 6 per cent.	5·30
Amortisation, maintenance, repairs, &c., 15%	13·25
Driver, stoker, and conductor	16·00
Firing	1·42
Oil waste, &c.	5·70
	41·67
Plus 10 per cent.	4·16
Total daily expenses	45·83

The variable expenses and working cost for a daily journey of 66 miles are as under:—

Working cost per passenger-mile, with baggage and 220 lbs. of goods—

With ¼ load	·108 franc.
„ ¾ „	·055 „
„ full load	·037 „

Working cost per passenger-mile, without baggage—

With ¼ load	·077 franc.
„ ¾ load	·040 „
„ full load	·027 „

From these figures it will be seen that the vehicle is exceedingly economical.

The next vehicle in this series is the Scotte steam passenger train, No. 3 (*see* p. 169). This consists of a steam tractor and a passenger car.

On the tractor is space for 11 passengers, while on the car is accommodation for 15; there is also space for baggage or goods. According to the maker this train can travel on a good road at 7½ miles per hour, while on steep gradients this is reduced to 3¾ miles per hour. The total price of the train is 26,000 francs, of which the tractor costs 22,000 francs.

Dimensions, Weights, &c.

Total length of train		34·44 feet.
„ breadth „		5·70 „
Length of tractor		17·71 „
„ car		15·58 „
Weight of tractor empty	13,156 lbs.	= 5·87 tons
„ on fore wheels		9,570 lbs.
„ on rear wheels		3,586 „

In working order:—

Water	1,490 lbs.	
Coke	264 „	
Three hands	462 „	
Sundries	88 „	
Weight on fore wheels	11,660 lbs.	= 6·87 tons.
„ rear wheels	3,740 „	
Useful weight	5,500 „	= 2·45 tons.
Total weight on fore wheels	14,300 „	
„ rear wheels	6,600 „	
Grand total weight	20,900 „	= 9·33 tons.

The proportion of useful weight to dead weight is 0·357, and the proportion of useful weight to total weight is 0·263.

Cost of Working, &c.

Price of train, 26,000 francs.

	Francs.
Interest 6 per cent.	5·20
Amortisation, repairs, &c., 15 per cent.	13·00
Driver, stoker, and conductor	16·00
Firing	1·35
Oil waste, &c.	3·50
	39·05
Ten per cent.	3·90
Fixed daily expenses	42·95

DE DION ET BOUTON TRACTOR.

SCOTTE STEAM PASSENGER TRAIN.

SCOTTE GOODS TRAIN.

Variable Expenses with Load and Working Cost.

Working cost per passenger-mile, with baggage and 220 lbs. goods :—

With ¼ load	·113 franc.
„ ¾ load	·058 „
„ full load	·040 „

Working cost per passenger-mile, without baggage :—

With ¼ load	·09 franc.
„ ¾ load	·042 „
„ full load	·030 „

This system is also very economical in working, and for outlying districts sparsely inhabited it is eminently suitable. It, however, requires very good roads.

The third vehicle in this series is the Dietrich Petroleum Lorry, No. 8. This lorry has been designed to carry a load of 2,640 lbs. at a speed of 6·2 miles per hour on the flat and 2½ miles per hour on steep grades. According to the builders, the useful weight may be as much as 3,300 lbs. on the flat and on good roads. The price of the vehicle is 6,000 francs.

In the second classification is comprised those vehicles intended for goods traffic. These included a *camion, Anglicé* lorry, by De Dietrich et Cie., actuated by petrol, and a Scotte automotor hauling a lorry. These two latter we shall proceed to describe.

The former vehicle is composed essentially of a metallic framework, resting on springs supported by the axles. Below the frame, and between the front wheels, which are used for steering, is placed the petroleum motor, developing 6·5 H.P. on the brake. Above is the seat for the driver, who has all the levers for driving and changing speed, &c., immediately under his hand. The transmitting gear is fixed under the frame, between the rear wheels. The load is supported almost entirely by the driving wheels. The body of the vehicle is very low down, in order to facilitate loading. Under the seat are placed three reservoirs, containing 123 pints of water, 55 pints of spirit of 710° specific gravity, and 9 pints of oil. The wheel base is 6·56 feet. The width of the vehicle is 4·85 feet, and the length 10·75 feet. The motor, of 6½ H.P., is of the type invented by Amédée Bollée, of Le Mans, and is fired by incandescent tubes. There are two horizontal cylinders with water jackets, and the vaporised water escapes as a visible exhaust. A float and a valve keep the water in the jacket at a constant level. The water enters the jacket by force of gravity, without the use of a pump. By this arrangement the motor does not become over-heated. The engine, crank, and piston-rods are enclosed in a case bolted on to the under-frame. The engine runs at 660 revs. a minute, and there is an impulse at every revolution. A governor is also provided. The crank-shaft carries a pulley on which runs a belt half its width. This belt passes over another pulley of the same diameter at the rear of the vehicle parallel to the crank-shaft, and also carries a loose pulley. This belt, which runs at a uniform speed, is employed to ~~put the~~ motor in and out of gear. The belt is of rubber, and runs at about 33 feet per second. It undergoes a tractive effort of 106 lbs., and this, after running about 2,500 miles, lengthens it by ·78 inch, but once the belt is tightened, by means of special bolts, there is no more trouble from this cause. The variable speed gear is situated at the rear, and is composed of two parallel shafts running on to each other by spur wheels, which allow of speeds being attained of 2·5, 4·3, 7·5, and 10 miles per hour, and a reversed speed of 2·5 miles. The shaft at the rear carries the differential gear and a band brake. At its extremities it is connected by bevelled rods with the driving wheels, to which are fixed toothed wheels for this purpose, and, as the rods are jointed, they readily yield to the movements of the springs, and the effort on the driving wheels is fairly constant. The whole of the gear is protected in a rudimentary fashion from the dust by means of a case of sheet iron, which may be easily removed when it is necessary to inspect or lubricate the gear. All the levers are arranged compactly under the hands of the driver, and the mechanism is so devised that the motor is automatically thrown out of gear when the brake is applied or the speed changed. Besides the brake band there is a powerful brake on the tyres, which is operated by hand. The principal parts are made of hardened steel, and the bearings are of phosphor-bronze. They are all made to template. According to the builders, the consumption of petroleum spirit of 700 to 710° is about 1¾ pints for 2½ miles, and this is also about the amount of water consumed. Enough supplies can, therefore, be carried for a run of 80 miles. The commercial speed ~~was found to~~ be from 5 to 5½ miles per hour.

Dimensions, Weights, &c.

Length	10·4 feet.
Breadth	4·8 „
Wheel base	6·5 „
Weight empty	2,486 lbs.
Driver	154 „
Water	154 „
Petrol	43 „
Cargo	2,040 „
Weight in working order on fore wheels	1,540 „
„ „ rear „	3,960 „
Total weight	5,500 „

Ratio of cargo to dead weight. ·92, and to total weight, ·48.

(*To be concluded.*)

Not an Enthusiast for Automobilism.—The Brighton magistrates were applied to recently by a visitor from London who objected to motor-cars. He stated that he was an invalid, and had come down to Brighton with his horses for the benefit of the change. But wherever he went he seemed to be pursued by motor-cars. One of them the other day so frightened his horses that they bolted and did considerable damage to the carriage. He wished to know whether he could sue the owners of the car for the damage. The stipendiary magistrate told the applicant that he was afraid he could not do so unless the driver of the car had been negligent in some way or other. The chief constable pointed out that if a horse was restive at the approach of a motor-car the driver of the horse had merely to hold up his hand to compel the car to stop until the horse had passed; if the driver of the car failed to stop he rendered himself liable to prosecution. But why should an invalid of all persons drive a horse or be driven in a horse-drawn vehicle? Is not this a risk that one wilfully undertakes?

TRACTION ON HIGHWAYS.

By Sir DAVID SALOMONS, Bart.

A YEAR or more has passed since I published some facts and figures concerning the power which should be carried by self-propelled road carriages. The final result of my opinion—based upon experiments made by others as well as by myself, taken in conjunction with the legal limit of speed for such carriages in this country, and taking into account all hills which are likely to be encountered, namely, inclinations up to 10 per cent.—was that 12 H.P. per ton is the necessary power to be carried.

Great objection was taken to those figures at the time, especially by those who had their "own axes to grind," and who were trying to induce the public to believe that 4 H.P. was sufficient for all practical purposes. Even some scientific journals contended that we ought to be thankful for small mercies, and that if we can get along without horses mankind ought to be content, when meeting a hill, to advance at a crawling pace.

The French, who have taken the lead to the present day in horseless traffic, have at last come round to the opinion that 10 H.P. per ton is about the right thing, but they are pleased to get in more power when it can be done conveniently.

The object of this short article is to show that the figures I gave previously were not simply mythical, and for the purpose of showing the method of calculating it is my intention to use the decimal system, being so much more convenient than the English method.

The French *tonne* is practically the same as the English ton, being only a few pounds lighter. The French horse-power, 75 kilogram-metre-seconds, differs inappreciably from the English horse-power. A kilogram equals 2¼ lbs. For the purpose of making the calculations simple, friction will be entirely disregarded, and taken into account at the end.

From the well-known formula it can be shown that if a weight of one *tonne* rests upon a frictionless plane inclined at a given percentage to the horizontal, the force acting parallel to such plane, to keep the weight from slipping down the plane, will be equal to 10 times the percentage of inclination in kilograms.

Thus, on a 5 per cent. inclination, 50 kilos. would be the force to be applied to keep the *tonne* from sliding downwards, and on a 10 per cent. hill 100 kilos., and so on.

Now, we will assume motion, *i.e.*, that the *tonne* is going to move up the incline: 75 kilogrammetre-seconds acting for one hour would raise 75 kilograms 3·6 kilometres. Consequently, 13·33 H.P. would be necessary to raise one *tonne* 3·6 kilometres against gravity.

If we now take the speed of one *tonne* up a plane, inclined at 5 per cent., at the rate of 20 kilometres per hour, and for a distance of 20 kilometres along the plane, the weight will have risen one kilometre against gravity. Consequently, the horse-power developed will be equal to $\frac{13·33}{3·6}$, *i.e.*, approximately 3·7 H.P. If the inclination is 10 per cent. the horse-power will be doubled, *i.e.*, 7·4; and so on in proportion for all inclinations.

The English speed of 12 miles per hour is about equivalent to 19 kilometres per hour, *i.e.*, from any result obtained about one-twentieth of the power should be deducted when dealing with the English maximum speed.

It now only remains to add something for friction. This generally varies from 25 to 100 per cent., and 50 per cent. is a very reasonable figure for the use of carriage constructors. It is rare that hills are to be found of greater inclination than 10 per cent., except in a few districts, and then only for short distances.

If, therefore, it is desired to run a carriage with its load weighing 1 ton at 12 miles per hour, at all times and upon all hills up to 10 per cent., as the horse-power necessary without friction is 7·4, it becomes with friction 11·1 H.P.; consequently, it will be seen that my proposal to employ 12 H.P. was not wide of the mark, and that the French proposal to use 10 H.P. is very near my estimate. The object I had in view in giving 1 H.P. more was to allow an advantage in the case of rough roads, and to cope with steeper inclinations which might be met with. If the hills are badly paved, or in a rough condition, considerably more than 12 H.P. is necessary, as the friction may rise to at least 100 per cent., in which event it will be observed that 15 H.P., or even more, may be necessary.

[While the foregoing investigation and the deduction therefrom are perfectly correct, we may point out that the same result can be arrived at in a much more simple and more accurate manner. Our distinguished correspondent has confined himself to one weight at one speed with an indefinite frictional resistance. Let us consider the power necessary to propel a vehicle of any given weight at any given speed, up or down any inclination, against any given resistance. We have given the following formula in the AUTOMOTOR POCKET-BOOK (p. 79), and, as will be seen elsewhere, we stated it quite recently before the S.P.T.A. We give the matter this repeated publicity, as it is really astonishing to find how crude and incorrect are the opinions prevailing as to the power required to propel vehicles. Really it is not a question of opinion but one of physical law confirmed by actual fact and measurement:—

Let W be the weight of vehicle in tons;
V " speed in miles per hour;
r " resistance in lbs. per ton of vehicle;
α " angle of grade; and
H.P. " horse-power required (actual);

then—

$$\text{H.P.} = (r \cos \alpha \pm 2240 \sin \alpha)\ \text{W.V.}/375.$$

Thus, to propel a vehicle weighing 1 ton at 12 miles per hour up a 5 per cent. grade ($\alpha = 2° 52'$) against a resistance of 50 lbs. per ton, will require 5·18 H.P., or, allowing 20 per cent. for internal friction in engine, &c., 6·2 I.H.P. For a 10 per cent. grade ($\alpha = 5° 43'$) $8\frac{3}{4}$ actual or $10\frac{1}{2}$ I.H.P. would be required. A resistance of 50 lbs. is an average value. On badly-maintained roads the resistance may be twice this, while on asphalte paving it will not exceed 20 lbs.—ED.]

LIVERPOOL MOTOR AND CYCLE SHOW.

THE following is the report of the judge, Professor Hele Shaw:—

"I beg to report that I have carefully examined the various motor-cars and motor-cycles at the show, not only within the building, but by trials on the streets. I have pleasure in stating that, whereas last year there was no motor-car which worked satisfactorily, this year there are no less than nine capable of fulfilling the requirements of public traffic, while all of those which took part in the street trials completed their runs in the crowded streets in an entirely satisfactory manner. I unhesitatingly commend the award of the gold medal to the Daimler Motor-Car Company (Limited), of Coventry, who have supplied the motor, together with the frame, wheels, and gearing of most motor-cars shown, and also various bodies of some of the best finished cars.

"I further recommend the award of the silver medal to Messrs. J. Holdsworth and Company, of Liverpool, exhibiting the Victoria motor-carriage. The award of the bronze medal I recommend to Mr. A. W. Goodall, of Blackpool, for the excellence of his work and fittings of the body of the motor-car wagonette which he has attached to a Daimler motor-carriage.

"Coming to the motor cycles, I recommend the gold medal to the Beeston Cycle Company (Limited), Coventry, who exhibit, as last year, a motor-tricycle of the De Dion type. This motor-cycle has been considerably improved by the substitution of the flame ignition in the place of an electric battery, and I was able to make personal trial of this in the crowded streets. I found ignition by this means entirely satisfactory, and the tricycle itself an admirable one in every respect. One of these machines, I am informed, ran from Rhyl to Liverpool in two hours and ten minutes."

The Gulzow-Fiedler Cell.—We understand that the active material employed in this cell is a mixture of minium and litharge with acetate of potassium.

A Well-Merited Distinction.—Among those whom the Queen delighted to honour on the occasion of the New Year was Mr. Jas. Dredge, one of the editors of *Engineering*, who has been given a C.M.G. Although this distinction is conferred for services rendered in connection with the Brussels Exhibition, most persons conversant with engineering literature will agree that it might have well been bestowed for services rendered to the engineering profession. Mr. Dredge is not only a most distinguished technical journalist, but he is the author of several standard works on the higher branches of the profession. We cordially congratulate Mr. Dredge.

CLARKSON & CAPEL'S NON-LUMINOUS AND SILENT-FLAME LIQUID FUEL BURNER.

MESSRS. CLARKSON AND CAPEL, two engineers who have devoted considerable attention to the subject of liquid fuel, have invented a burner which, if it does all that is claimed for it, will be of exceeding value. As is well known, one of the principal objections to the use of liquid fuel for automobiles is the noise made by the issuing gas. The object of Messrs. Clarkson and Capel has been the production of non-luminous and silent flame from liquid hydro-carbons, particularly what are commonly known as ordinary paraffin or lamp oil, as opposed to the more volatile hydrocarbons. The oils which they propose to utilise are those having a specific gravity of not less than 0·8, and a flash point of not less than 73° Fahr.

In carrying out this invention a vaporiser is employed consisting of a hollow vessel with an oil supply and a vapour exit. In connection with the oil supply is an air vessel for the purpose of regulating the supply, the fluctuations and back pressure, and if desired a number of wires may be employed arranged longitudinally in the supply pipe for the purpose of further regulating the rate of travel of the oil. The oil may be heated before it reaches the vaporiser, and where the flame is used for generating steam, a convenient way of doing this is to carry the oil-supply pipe through the steam boiler.

The exit pipe from the vaporiser delivers the vapour of a mixing chamber in connection with the burner, which may be situated beneath the vaporiser; the jet nozzle from the vaporiser delivers into the open end of a pipe or entrance to the mixing chamber, so that atmospheric air is drawn into the mixing chamber together with the vapour and a mixture is produced therein having a sufficient proportion of atmospheric air to produce a non-luminous flame when burnt in the burner. In the mixing chamber, and preferably near the top, is a gauze or similar partition through which the mixture has to pass to the burner, a suitable form of which consists of a series of alternate troughs and burner slits. A further supply of air is obtained by deflecting plates, which throw the air which is supplied to the burner outside the mixing chamber on to the flame, and particularly to the troughs, so as to give a full supply. The entrance of the air and vapour into the mixing chamber may be through a tube either wholly contained in the mixing chamber or partly extending outside it. The burner may consist of a cast-iron or other grid arranged as already explained in alternate troughs and burner slits. The grid may also be made hollow and form the vaporiser. The mixing chamber may be protected or lagged with any suitable non-conducting material, or it may be jacketed and heated air supplied to the space.

The mixing chamber is heated; in ordinary work by the heat of the flame, but for starting purposes the following arrangement may be employed:—Two gas blow-pipes are fixed, one directing its flame on to the vaporiser, and the other directly into the mixing chamber. These blow-pipes are arranged in the following manner:—A small vessel is provided for each and supplied with oil sufficient to last until the burner is properly started, but as it is desirable that the flame directed into the mixing chamber should be cut off before that directed to the vaporiser, the supply of oil to the blow-pipe for the mixing chamber is preferably less than that to the vaporiser. This may be easily effected by having a primary vessel with a partition dividing it into two unequal sized receptacles, each communicating by a separate pipe with its respective blow-pipe vessel, taps being used when necessary. The jet of air for the blow-pipe may be provided by a hand-bellows, fan, or the like.

To start the burner, all that is required is to turn on the supply of oil for the blow-pipe, charge the blow-pipe receptacles, ignite them and apply the blast, and as soon as the mixing chamber flame goes out, the supply of oil to the vaporiser may be admitted, and the rest is automatic. A taper needle regulator may be employed for the supply from the vaporiser to the mixing chamber, the needle being preferably applied to the nozzle from its open end, and being loosely carried in the arm or equivalent by which it is adjusted in the nozzle. The blow-pipe flame, previously described as heating the interior of the mixing chamber, may, if desired, be applied to the exterior of that chamber.

A modified form of vaporiser would consist of a main tube, to which the oil would be supplied, and a suitable number of branches from which the vapour would be taken. In the accompanying drawings, Fig. 1 is an elevation partly in section of the apparatus; Fig. 2 is a plan of the mixing chamber; Fig. 3 is a plan of a modified construction of burner grid; Fig. 4 is a section on the line

4—4 of Fig. 3. The fuel is led from a suitable storage tank by a pipe, A, into a cylindrical casing, B, which constitutes the vaporiser. The vapour from the latter is conducted through a pipe, C, to a jet nozzle, D, whence it passes in a stream into the flared end, E^1, of a tube, E, which projects into the box or casing, F, forming the mixing chamber.

FIG. 1.

The top of the mixing chamber is closed by a gauze, or perforated metal partition, G, above which is arranged a burner grid, H, hereafter to be more particularly described. The bottom of the chamber is sloped away from that side into which the tube, E, projects, so that any vapour which may condense within the tube, E, or chamber, F, will drain down to one end of the latter, whence it may conveniently be conveyed away by a syphon tube, J, leading into a cap, J^1. In order to regulate the supply of fuel, and prevent fluctuations and back pressure, an air chamber, A^1, is placed in communication with the pipe, A, which conducts the fuel to the vaporiser. If the burner is employed for heating a steam generator, this pipe, A, may be led through such generator in order to heat the fuel previous to its introduction into the vaporiser. The latter, as shown in Fig. 1, is formed as a hollow cylinder, B, the fuel being introduced at the lower part of one end, as at B^1, while the vapour is conducted away from the upper part of the other end, as at B^2, this arrangement obviating the risk of any unvaporised fuel passing to the jet nozzle, D. The jet nozzle, D, comprises a cylindrical casing, one end of which is closed by a plug, D^1, while the other end, in which is the orifice, is formed conical, as at D^2. In the orifice lies the tapered end of a regulating needle, K, the other end of which is carried loosely upon the end of a lever arm, L, adjustably secured by a clamp, L^1, upon a pivoted tubular or other rod, M. By rotation of the rod, M, by suitable means, the end of the needle, K, is introduced more or less into the orifice of the jet nozzle, D, and the flow of vapour therefrom controlled as required.

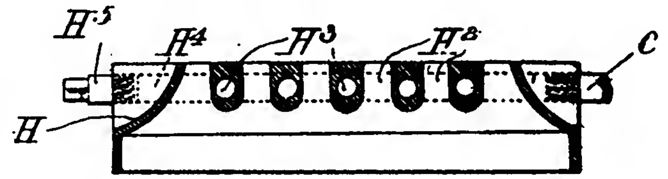
The tube, E, with flared end, E^1, into which the vapour from the nozzle streams, may be formed cylindrical, or of oval or other cross section, and may project for a portion of its length on the outside of the mixing chamber, F, as shown in Fig. 1, but, if preferred, the whole tube, E, E^1, may lie within the chamber, F, the flared end, E^1, being flush with the side of the chamber.

Where the bottom of the chamber, F, is sloped away towards the point where the syphon tube, H, is situated, as shown in Fig. 1, the tube, E, is constructed at its inner end so that the vapour condensed therein may drain down towards the same point. This may be accomplished by either slightly enlarging the tube, E, from the flared end, E^1, inwards or by cutting a sloping groove or channel longitudinally along its interior, or by merely inclining the tube towards the drainage point.

The burner grid, H, in the form shown in Figs. 1 and 2, is constructed as a plate of conveniently rectangular shape so as to fit

longitudinal passages, H^4. The latter run through the grid from end to end, one end of each being closed by a plug, H^5, while to their other ends at H^6 are connected the pipes A and C for introducing the fuel and leading away the vapour respectively. The arrangement of the plugs, H^5, and connections, H^6, to the tubes, A and C, is such that the hydrocarbon to be

FIG. 4.



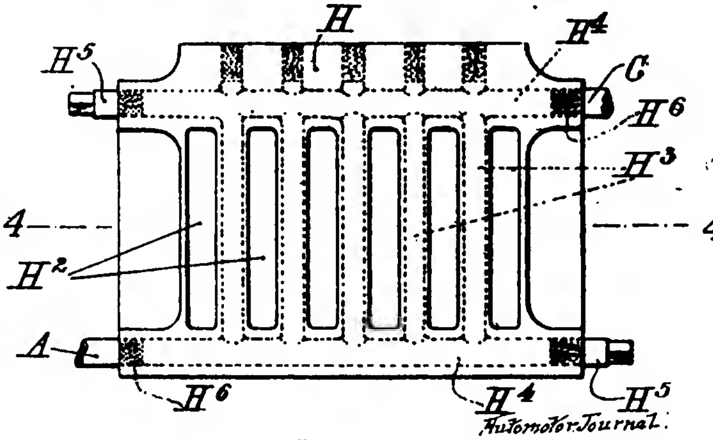


FIG. 3.

vaporised is led in at, and the vapour led away from, diagonally opposite points of the rectangular hollow grid, H.

As a means for obtaining a preliminary heating of the vaporiser, B, and also the mixing chamber, F, the following blow-pipe device may be employed:—A fuel receptacle, N, of suitable size and conveniently located is divided into unequal parts by a partition, N¹. A tube, O, leading from each of these parts terminates in a box, P, containing an asbestos or other suitable form of wick. A blow-pipe, Q, is so situated in relation to each wick box, P, that the current of air from it will direct the flame from the hydrocarbon with which the wicks are saturated on to the vaporiser, B, and mixing chamber, F, respectively.

By reason of the difference in size of the two compartments of the receptacle, N (the smaller compartment being in communication with the wick box, P, for heating the mixing chamber, F, while the larger compartment is connected to that for heating the vaporiser, B), the preliminary heating of the mixing chamber will be stopped before that of the vaporiser ceases, owing to the supply of fuel for the former being less than that for the latter. The object of this arrangement is to obviate risk of the vapour being ignited as it issues from the nozzle, D. By employing a syphon tube, such as H, or some similar device which will maintain the drainage opening from the mixing chamber, F, always closed, the escape of vapour from the chamber is prevented.

Ten claims are made, and the number of the Specification is 1,794 of 1897.

THE AUTOMOBILE FIASCO.

UNDER this headline, *Engineering*, in its issue of 21st ult., publishes the following letter from a Mr. Evacustes A. Phipson, of Selly Oak, Birmingham:—

"Sir,—As modern mechanical talent does not seem equal to the task of designing perfectly satisfactory horseless vehicles, although having at disposal all the marvellous scientific inventions of the nineteenth century, it might do worse than take lessons from the experiments of three generations ago, when steam-carriages ran successfully on many of our roads, and were only prevented from becoming universal by the rapid rise of railways, the introduction of which, unfortunately for the former industry, happened at just about the same time.

"My grandfather, Joseph Phipson, constructed at Birmingham, about the year 1825, from the designs of an ingenious American named Church, a steam-coach which ran on several occasions between Birmingham and Coventry, sometimes attaining a speed of 30 miles an hour, while Tangye Brothers manufactured an elegant car, called the "Cornubia," which travelled regularly at the rate of 20 miles an hour. It is surprising, indeed, that this firm does not again start in the manufacture of automobiles, for which its previous experience should pre-eminently fit it, the only explanation apparently being that the business is now so large that the venerable heads of the establishment fear to venture upon any further extension. This is much to be regretted, not only because to them is justly due the honour of perfecting their own invention, but also because, should the motor industry, like that of the bicycle, find its seat in Coventry, the effect will be, on the one hand, still further to depress the already none too prosperous trade of South Staffordshire, and, on the other, to finally extinguish the picturesque and old-world flavour which still attaches to the recently so beautiful and romantic city of Coventry."

We beg to make some observations upon this. The reason why our contemporary speaks, even in headlines, of an automobile fiasco is, we suppose, because the prophecies and promises of those who a little more than a year ago "found automobilism," and promptly boomed it in the approved manner, have not been fulfilled. Taken in this sense we do not object to people speaking of the automobile fiasco. Coming to Mr. Evacustes A. Phipson's letter, which is easily answered, this gentleman may rest assured that modern mechanical talent is quite capable of making perfectly satisfactory automobile vehicles, and that without taking any lessons from previous practice; indeed, in many things this latter would have to be carefully departed from. Mr. Phipson is apparently oblivious of the fact that up to some 15 months back automobilism on roads, save with heavy slow-moving traction-engines, was illegal. Hence the later school of engineers, as represented by Messrs. Yarrow, Thompson, and others, had no incentive to proceed beyond preliminary or experimental automotors, but those that they did build were vastly superior to anything which had preceded them; they were, in fact, distinct and large advances upon the then existing practice.

Since the Locomotives on Highways Act has been passed the progress has been if not rapid at any rate substantial; the oil-motor has been successfully applied for purely commercial purposes of automobilism, and we now get within the compass of a lady's travelling trunk an 8 or 10 H.P. motor, while within the compass of a hat box we can put a 1¼ H.P. motor. In the Lifu steam-van we have a most marked advance upon anything in Church's or Tangye's vehicles. If water-tube boilers, very high and superheated steam, liquid fuel, and compound engines be not progress, we should like to know what is. We have, too, in less than a year from the passing of the Act electrical cabs running in London; surely there has been progress, and surely our engineers are equal to the task of designing perfectly satisfactory horseless vehicles. If Mr. Phipson is disappointed because there are no heavy automotor vehicles, he must remember that the Act discourages this class of vehicle, while outside the large towns the roads are much too soft to enable heavy vehicles, weighing fully loaded some 10 to 12 tons, to traverse them at a paying speed. There is also the uncertainty as to whether the local authority would not endeavour to prohibit such vehicles. Without discussing the matter further it will be allowed that, considering the prejudice and legal disability which have encompassed, and still does encompass, automobilism, and remembering that the latter disability has only been lessened a little more than a year, the progress made on the whole is not unsatisfactory. It must also not be forgotten that in everything affecting public requirements we move slowly. It has taken our wooden municipalities some 10 years to make up their minds about electric traction. A system or device may be invented in Great Britain, but its application will be in the United States, France, or Germany years before we begin to dimly perceive that there is anything in it.

WARWICKSHIRE MAGISTRATES AND THE LOCAL GOVERNMENT BOARD.

A FEW months ago we drew attention to the exceedingly unjudicial attitude adopted by some of the Warwickshire magistrates in dealing with automotor vehicles. These magistrates—persons dressed in a little brief authority—actually had the impudence lately to address a letter to the Local Government Board requesting that body to order that all automotor vehicles should be numbered and registered. A more improper and impudent request it would be difficult to imagine. Who on earth are these persons, and who appointed them? The fact that it is possible that such illiberal and unjudicial persons can be appointed at all is one of the best reasons for the total abolition of that vicious and feudal system which entrusts the appointment of county magistrates to lord lieutenants.

County magistrates are often ignorant, narrow minded, but wealthy. They have no more, or rather less, legal knowledge than a London policeman. *Truth* has for years exposed the ignorance and intolerance of these county bumbles. Only quite recently the Lord Chief Justice had to animadvert very strongly on the methods of some county magistrates. Needless to say these persons are, with few exceptions, rabid Tories of the most pronounced type—not that they are to be blamed on this account, but because their Toryism takes the form of a blind and Chinese-like conservatism. They are bitterly hostile to change, and to those who differ with their political or religious opinions. It was this blind and jealous conservatism on the part of the county magistracy that made the roads impossible to Gurney's steam coaches, and for 60 years succeeded in rendering automobilism illegal. This same illiberal spirit still, as we see, survives, and we have the Warwickshire magistrates every bit as ignorant and as conceited as Justice Shallow, who, by the way, also was a Warwickshire man, endeavouring by all means to hinder the progress of the new industry. It is a scandal that the power to make recommendations to the Local Government Board should be entrusted to such men.

We are, however, glad to say that the attempt made by these persons has so far utterly failed; the Local Government Board curtly refused to sanction or issue any such regulation. This incident, however, shows the great necessity for Automobile Clubs, not only for the purpose of carefully safeguarding the interests of automobilists when they have the misfortune to appear before such persons as these Warwickshire justices, but also to see that the Local Government Board does not make any alteration in the regulations without the consent of automobolists.

HORSE-DRAWN CABS v. ELECTRIC CABS.

THE actual expenses of operating vehicles are very difficult to obtain in this country, both the costermonger and the railway director displaying a suspicious reticence when asked for information, which is not a little amusing. Our French contemporary, *La France Automobile*, has, however, succeeded in obtaining such information as is applicable to Paris, and we reproduce it here as being an eminently instructive comparison. Moreover, we think that the prices do not differ greatly from those ruling in London:—

Daily Cost of a Horse and Cab.

	Francs.
General expenses	0·53
Financial expenses	0·30
Tickets (cabman's)	0·01
Apprenticeship and sundries	0·05
Provident fund	0·07
Fire insurance	0·02
Lighting of carriages and depôts	0·11
Heating " "	0·02
Water	0·03
Syndicate expenses	0·05
Accidents and damage	0·35
Rent of depôts	1·05
Depôt staff and employés	0·99
Rates and taxes	2·26
Food, shoeing, and wear and tear of horses	6·65
Renewing and wear and tear of rolling stock	2·74
Wear and tear of property	0·21
12*s.* 4*d.* =	15·44

Daily Cost of an Electric Cab,

the number of carriages being equal in the two cases.

	Francs.
General expenses	0·17
Financial expenses	0·08
Tickets (cabman's)	0·01
Apprenticeship and sundries	0·05
Provident fund	0·04
Fire insurance	0·01
Lighting of carriages and depôts	0·05
Heating " "	0·01
Water	0·06
Syndicate expenses	0·05
Accidents and damage	0·24
Rent of depôts	0·35
Depôt staff and employés	0·50
Rates and taxes	1·50
Electrical energy and accumulators	2·20
Renewing and wear and tear of stock	2·74
Wear and tear of property	1·07
7*s.* 4*d.* =	9·13

Allowing for an under-estimate there is still a large balance in favour of the electrical cab.

A Cyclometer.—We hear that the cyclometer of M. Foureau, of 54, Rue de Chabrol, Paris, gives great satisfaction, being simple in construction and accurate in working. Such an indicator should command a ready sale. We may say that we are having one of these machines tested for motor-cars, and shall describe it in a future issue.

Low-Test Petroleum.—At its meeting on February 1st, the London County Council, without discussion, passed the following motion:—"That in view of the dangerous nature of low-flash petroleum oils sold in London, and the numerous fatal and other accidents that occur through the use of such oils in lamps, it be referred to the Public Control Committee to further investigate the causes of such accidents with a view to representations being submitted to Parliament as to the desirability of raising the flash-point fixed by the Petroleum Acts."

SPREADING THE LIGHT.

WE are glad to observe from time to time evidences that the idea of automobilism is slowly permeating the public through the medium of the newspapers, but what is surprising is that the daily paper, usually so conspicuous for its dense ignorance on matters mechanical, is at length perceiving that it is now necessary to write with some show of knowledge on such things. As an example, we reprint an intelligent article from the *Standard* on Mr. Worby Beaumont's paper read before the Society of Engineers (published elsewhore). Says our contemporary:—

The Presidential Address given before the Society of Engineers by Mr. Beaumont, on February 7th, contained some very suggestive reflections. At no distant date he expects to witness considerable changes in our street and road traffic. Notwithstanding all that can be done by railways and tramways, we are reminded that there are millions of passengers and tons of goods, year by year, waiting to be provided with better means of transit. Scattered over the country we have a hundred thousand miles of roads, with gradients costing, in the aggregate, enormous sums of money in providing animal power to surmount them, and which it is complained put the most effective stop on the cheapening of transit of goods between railway stations and the outlying villages and agricultural districts. There appear to be certain very undesirable limits to the distributing capacity of railways, and it has become evident that the common high road must again receive the attention which was given to it under Telford and others in the early part of this century. Mr. Beaumont estimates that road improvement throughout Great Britain would effect a saving in the cost of keeping and working horses to the extent of three and three-quarter millions sterling per annum. On this basis it is calculated that a hundred millions of "national capital" could be expended by engineers to the great advantage of the public. Where the money is to come from is a difficult problem. But it is to be hoped that something will be done. The drawback seems to consist in the fact that the benefit will fall on individuals who cannot very readily be made to bear the cost. It is perfectly certain that our railways need to be supplemented, so as to put them in proper communication with the outlying localities. We observe that Mr. Beaumont has faith in motor-cars, while he looks upon tramways as nuisances in the towns, though desirable upon the open highways. Concerning the metropolitan traffic, a visit to many of the London tramway and omnibus centres and starting-places is said to show that a density of traffic is being rapidly reached which it will be impossible to cope with, "if the streets are to be anything more than lines of free railways on which the driver of every car and omnibus and coal wagon is traffic manager." This latter function, we apprehend, rests rather with the police, but their labours will grow heavier unless the motor-car comes to their relief by partially superseding horses, and rendering unnecessary the transport of their fodder, although even this seems to offer but a slight and passing remedy, so long as population increases. Deep underground railways will, no doubt, effect much good; but, at the same time, they will develop a street traffic of their own. More suburban service railways are described as inevitable, and this involves the question of getting to and from the metropolitan stations. Engineers may study the subject, and capitalists may find the money; but, after all that can be done, we shall expect to find the streets of London generally crowded and occasionally congested.

Traction Data.—The following data relating to traction was given by Mr. E. Whythe-Smith, at the Institute of Electrical Engineers, on the discussion of Mr. Epstein's paper. He had made experiments to get the average pull on ordinary roads in the worst condition. Some of the results, expressed in pounds per ton in three different conditions of weather, are:—

Asphalte	22	23	22
Wood	22	31	36
Macadam (good)	52	50	49
Macadam	60	51	50
Macadam (soft)	97	51	52

P

LAW REPORTS.

The Ward Electrical Car Company.

Under the winding-up order recently made against this Company, the statutory meetings of the creditors and shareholders were held on January 26th before the Assistant-Receiver, at the Board of Trade offices, Carey Street. The Chairman said the facts relating to the case were somewhat peculiar. The Company was registered in October, 1888, with a capital of £300,000, and was apparently promoted by Mr. Ward in conjunction with a Colonel McMurdo, with a view to the acquisition of certain inventions relating to electricity and belonging to Mr. Ward; also to carrying on the business of electrical engineers. The whole of the capital—except the signatories' shares—was issued to Mr. Ward in return for his inventions, and he was also to act as managing director at £1,000 a year, payable only out of profits, or until the formation of a subsidiary company. The whole of the shares having been issued to the vendor, the Company had no working capital; but Mr. Ward entered into an agreement with Colonel McMurdo for the sale to the latter of 22,500 shares for £10,000, payable as to £1,000 to Mr. Ward and £9,000 to the Company. Colonel McMurdo died in May, 1889, having paid £4,362 on account. Mr. Ward then entered into an agreement with the receiver of his estate, under which 20,000 shares were to be returned to him, and he was to provide the Company with £5,000 for working capital. Mr. Ward further undertook to pay the Company's liabilities until December, 1890. The money received by the Company was used in developing the patents, but apparently without any definite results, and the only property acquired was stated to be a small amount of plant that had been seized by the landlord for rent and an omnibus which had been seized under a judgment. The directors in April, 1896, authorised Mr. Ward to sell the whole undertaking to a new Company for £35,000, payable as to £5,000 in cash and the remainder in shares. That scheme was not carried through, but subsequently Mr. Ward and a Mr. Marshall floated the London Electrical Omnibus Company (Limited) to acquire other inventions belonging to the former gentleman. The purchase price was £20,000 cash and £80,000 in shares, and was to be divided between the two promoters. Under the agreement with the first Company it was provided that all inventions and improvements thereon sold to that Company should become its property. The inventions sold to the second Company were stated to be improvements on the original inventions; so that a question of title would doubtless arise between the two Companies. Mr. Ward had stated his intention of handing over his shares in the new Company for the benefit of the old Company, and Mr. Marshall was now bankrupt in the London Court. The directors in August, 1892, resolved to issue debentures to a certain firm, and although there had been no actual issue, a claim to some of the Company's property had been maintained with success. The original patents had apparently lapsed, with the result that the only asset belonging to this Company was its interest in the London Electrical Omnibus Company (Limited). Accounts had been prepared showing unsecured debts of £863, fully-secured debts £2,435, and assets £1 9*s.* 1*d.* Mr. Ward intimated that he desired to present the shareholders with shares in the London Electrical Omnibus Company (Limited), which was now in a position to make a considerable profit by running electrical omnibuses. He had no doubt but that the old shareholders would consent to such an arrangement, as the shares would be of considerable value. The matter was left in the hands of the Official Receiver to be dealt with in the usual manner.

Rosser Cycle and Brake Company.—On January 15th Mr. Justice Romer heard the petition of the Rosser Cycle and Vehicle Brake Company (Limited), as represented by Mr. Romer, Q.C., for a reduction of capital from £50,000 to £10,000. The ground of the petition was that there had been a loss of £35,000, which was not represented by available assets. His Lordship sanctioned the reduction.

Brown v. I.E.S. Accumulator Company.—This case came before Mr. Justice Romer on the 5th inst., on a motion for judgment as a short cause in default of defence. The Company was incorporated in 1895 for the purpose of carrying on business as manufacturers of electrical batteries, and the plaintiff was the holder of debentures in respect of which the Company had made default. A Company named New and Mayne were also made defendants, they being interested in the taking of the accounts. Mr. Justice Romer made the usual order in a debenture-holder's action.

Estimates of Speed.—At the Justice of Peace Court at Hamilton, on January 24th, William Muir, motor-car driver, was charged with having, on December 21st, driven his motor-car at more than a reasonable speed during the darkness. Andrew Arbuckle, flesher, Blantyre, was on the night libelled driving a flock of sheep along the Glasgow Road at Blantyre, when the motor-car driven by the accused came up. He shouted to the driver, but he did not think he heard him, owing to the noise of the car. A number of sheep were injured. Various estimates were given as to the speed at which the car was going, one witness stating that it was going like an express train, another at between 20 and 30 miles an hour, and another at a "terrible" rate. On the other hand, it was stated that the rate of speed was not more than five miles an hour. The justices found the charge not proven.

Heavy Fines by the Warwickshire Magistrates.—At the Kenilworth Divisional Sessions (Milverton), on February 1st, Albert Thornbill Davis, of Coventry, was charged, under the Light Locomotives Act, with driving an autocar without proper lights attached, on the 22nd ult., at Kenilworth. The defendant had one light in the centre of the car, but none at the back. There was also another charge of obstructing the traffic by leaving the same car in a public thoroughfare and without proper attendance. The defendant was fined £2 and costs for the first case, the magistrates considering it a very dangerous practice to drive autocars without the lights placed in a proper place. The second case was dismissed. Some time after the case was over, Mr. Maddocks, solicitor (Coventry), appeared with the defendant, and asked the magistrates if they would reopen the case. He explained that he and the defendant had started to drive there on an autocar, but unfortunately the wind was rather high, and prevented them from arriving in time. They had allowed themselves plenty of time. He said the wind sometimes blew the light out. He thought they would reduce the fine if the facts of the case were better known. The application was not granted.

The Regulation of Street Traffic.—At Manchester on February 3rd, John Wilkerson, in the employ of the Theatre Royal Company, was summoned before the city justices for a breach of the local bye-law as to vehicles. On January 18th he was driving a motor-car, which is used for advertising the Theatre Royal pantomime, up Bridge Street, and, according to the evidence of a constable, he crossed into Deansgate on the wrong side, running the risk of an accident. The solicitor to the Theatre Royal Company explained that the defendant, finding that his foot-brake was out of order and that he could not apply the hand-brake without taking his eyes off the traffic, saw a chance of running safely into Deansgate by going inside the point where the officer was stationed. Thinking it wiser to break the rules of traffic rather than go on and risk the chance of an accident he did so, but pulled up as soon as he got safely into Deansgate. The defendant was an experienced driver, having for eight months before coming to Manchester been engaged in driving motor-cars in London. The justices, in consideration of this being the first case of the kind, imposed a penalty of 2*s.* 6*d.* and costs only.

No it Won't.—In a recent issue the *Globe* says:—"A motor-cab ran away in Fleet Street on Sunday, January 23rd, and hurt nobody; but next day the *Daily Telegraph* had a characteristic leader on the perils of the motor-cab. Yesterday a horse ran away and killed a man at King's Cross. Will the *Daily Telegraph* now oblige us with a leader in which the perils of horse traffic are discovered amid beds of flowery epithets?"

REVIEWS OF BOOKS.

The Engineering Magazine for February is not as interesting as it is usually. It contains, however, some good matter. Mr. Dugald Clerk discusses the economy and efficiency of the large gas-engine, and points out the difficulties in effecting proper scavenging of the cylinders. He is, however, sanguine that the present difficulties will soon be surmounted. Already an actual efficiency of more than 30 per cent. has been obtained from a Crossley gas-engine. Mr. Clerk thinks that in ten years' time we shall have gas-engines of 1,000 H.P.

Mr. James McKechnie, the engineering manager at the Vickers Company's Works at Barrow, contributes his third article on shipbuilding, and, needless to say, this is instructive, but more so from the economical than from the technical point of view.

We have said a good deal of late about the London County Council Fire Brigade and its obsolete equipment and inferior organisation. Here we have a capital descriptive and well illustrated article by Mr. Hugh Bonner on the equipment and organisation of a city fire department. The description refers to the New York fire service. We learn that the New York fire-engines have a capacity of from 350 to 1,100 gallons per minute. We have in London lots of old-fashioned crocks that spurt feebly 200 gallons per minute at their best, and but one engine that can deliver more than 500 gallons. The New York fire floats are also superior to ours. There are three boats with capacities of 2,500, 3,500, and 13,000 gallons per minute, and use hose ranging from 2½ to 6 inches diameter. Water towers and chemical fire-engines are largely employed. After reading this interesting article we certainly think that Colonel Rotton, the chairman of the London County Council Fire Brigade, cannot substantiate his extraordinary statement, to the effect that we have the best fire service in the world. We cordially recommend the article to the notice of all interested in the prevention and fighting of fires. There are other articles, but of less interest.

ELECTRICAL INSTALLATION RULES.—The Liverpool, London, and Globe Insurance Company have issued a small handbook containing their rules for electric lighting or power plant. Since the well-known "Phœnix" rules of some years ago, electrical pressures and apparatus have changed considerably, and house lighting is now effected by currents of a much higher voltage than was formerly the case. It has always been a characteristic of electrical work that it rather lends itself to flimsy construction, the stresses being electrical and not mechanical. In the early days of the industry much inferior work in wiring was to be seen, and the wireman was anything but a skilled mechanic. Leads were run in casings indifferently around fireplaces and in wash-houses, the same insulation being deemed suitable for a very damp place as for a very dry one. Such things, too, as ceiling roses, switches, and fuzes were of the cheapest and most trashy description, and as a consequence of this flimsy construction many fires occurred. Thanks, however, to the leading fire insurance companies, a considerable improvement has been effected. The Liverpool, London, and Globe Insurance Company have been foremost in this direction. Their rules have been drawn up by some of the leading electrical engineers, and we do not see that they can be much criticised. To us they seem to possess the great merit of fairness; they impose no onerous conditions, and only stipulate for good and faithful workmanship. They, in fact, embody the points of a good specification, and users of electricity would do well to insist upon contractors adhering to these rules whether they (the users) insure or not.

CATALOGUES.

MESSRS. THOS. CORBETT send us an illustrated catalogue of their agricultural machines. This well-known Shrewsbury firm has a very high reputation for keeping up to date and for excellence of manufacture. When it is remembered that they have obtained no less than 700 first prizes in various competitions, it will be evident that the firm has something to boast of. The catalogue is, of course, more interesting to the farmer. We would suggest to Messrs. Corbett that they would find automobile spring carts and wagons for farmers and country gentlemen a remunerative manufacture.

THE PANHARD "No. 6."

THE Hon. C. S. Rolls writes :—

As promised, I send you account of run I had by road from London to Wales towards the end of December last.

As you are aware, the carriage which I used on this occasion was the Panhard et Levassor, "No. 6," the winner of the Paris-Marseilles (1,070 miles) Race, fitted with an 8 H.P. Daimler-Phœnix 4-cylinder motor. I have modified the body somewhat and other details in this carriage, having now a wagonette body convertible into a phaeton.

Start was made from Knightsbridge at 8.22 a.m. on December 22nd with three persons and baggage on board, in a slight fog and hard frost, the route taking us through Hounslow and Slough.

At Maidenhead the first dismount was required, as I found it advisable to detach the ground "sprag" from the frame of car and take it inside, it having been doubled up by its failure to bite the ground immediately it was requisitioned to use when going up a hill, catching a little later with a jerk; after 25 minutes' delay here we proceeded through Twyford to Reading, where we spent about 40 minutes oiling over and renewing water supply at fire station; the next "watering place" was Hungerford, after which we covered several miles of the extremely undulating Wiltshire Downs, passed through Swindon without stopping, and arrived at that night's destination—viz., Purton—at 5.4 p.m., where we stayed with some friends. Distance for the day, 88½ miles. On the second day we left at noon, taking for 10 miles or so three extra passengers, our load on board (six persons, baggage, petrol, tools, and parts) being quite equivalent to eight people; the engines, however, took but little notice of this weight, running almost continuously on fourth gear. Beyond Cirencester trouble with heated pump bearing caused slight delay; dismantled, oiled, replaced, proceeded. I made good use of five brakes when descending Birdlip Hill (Cotswolds), being a mile of sharply-curved steepness; and an hour's rest was taken at Gloucester, during which we took in water and oiled selves and car. Took Ross and Monmouth in the evening, stopped for few minutes beyond Monmouth to resin the clutch, and arrived at The Hendre 7.57 p.m., the car and its occupants being white with frost. Average speed of running during the two days was 11 miles per hour.

It will be noted that water was only taken in twice on the first day and once on the second, although very mountainous work was done on the second day. Total distance, 150 miles.

Permit me to congratulate you heartily on your '98 AUTOMOTOR POCKET-BOOK, which I consider is a marvellous shilling's-worth.

PROPOSED EXHIBITION OF MOTOR-VEHICLES.

AT the annual meeting of the Tunbridge Wells Agricultural Society an important discussion took place as to a sum of £200, the proceeds of a motor-car exhibition at Tunbridge Wells, organised by Sir David Salomons, and for which the society lent the use of their own ground. This sum Sir David had promised to spend in prizes for a motor-car exhibition, and when approached a year ago he replied that the time had not arrived when the money could be profitably devoted to the purpose, and owing to company-mongering the progress of the industry had been greatly retarded. When satisfactory arrangements could be made he should have great pleasure in arranging a prize list. Lord Arthur Cecil said the question was whether the time had not arrived when they should again approach Sir David and ask him whether the exhibition could be held this year, and Mr. Austen remarked that the Royal Society were offering similar prizes this year. Mr. Machean doubted whether they should have room for anything of the sort. Mr. Austen suggested that they might have a three days' show and devote the third day to a motor-car exhibition. Mr. Williamson said as they lent the ground they ought to have more control over the money. The chairman said that no doubt Sir David would meet them in his own good time, and until then he did not see how they could discuss the matter. Mr. Pane said there was a question whether their ground was suitable. Major Simpson said he believed that Sir David was still of opinion that the time had not yet arrived for holding an exhibition. It was decided to refer the matter to the committee to again approach Sir David, and the meeting terminated.

NOTICES.

Contributions and articles likely to prove of interest to our readers will receive due attention, but in all cases the name and address of the writer must be given, not necessarily for publication.

All matter intended for publication should reach us not later than the 10th of each month, and be addressed to THE EDITOR OF "THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL," 62, *St. Martin's Lane, London, W.C. Stamped envelope must be sent if the manuscript is required to be returned. The Journal is published the middle of each month.*

All Advertisements should be addressed to F. KING AND CO., LIMITED, 62, *St. Martin's Lane, London, W.C., where Advertising Rates may be had on application.*

The Annual Subscription is 7s., including prepaid postage to any part of the world. Single copy 7d., post free.

Cheques and Post Office Orders should be made payable to F. KING AND CO., LIMITED, *and crossed London and County Bank; otherwise no responsibility will be accepted.*

Special Notice.

THE AUTOMOTOR AND HORSELESS VEHICLE JOURNAL *can be obtained from all* MESSRS. W. H. SMITH AND SON'S *bookstalls, and the following Agents :—*

London : POTTLE AND SONS, 14 and 15, Royal Exchange, E.C.
Wholesale : BRETT AND CO., 5, Pilgrim Street, Ludgate Hill, E.C.
Birmingham : J. MCCANN, 37, Union Street.
Manchester : JOHN HEYWOOD, Deansgate.
Newcastle-on-Tyne : C. C. ROSS, 35, Side.
Paris : HOMÈRE MOREAU, 97, Rue Nollet.
Victoria (Australia) : PHILLIPS, ORMONDE, AND CO., 169, Queen Street, Melbourne.

When any difficulty is experienced in procuring the Journal from local newsvendors, intending subscribers can obtain each issue direct from the Publishing Office, by forwarding remittance of 7s. for 12 months' subscription, post free (or at the rate of 7d. per copy).

Proprietors and Publishers—F. KING & CO., LIMITED, 62, St. Martin's Lane, London, W.C.

The Automotor and Horseless Vehicle Journal.

A RECORD AND REVIEW OF APPLIED AUTOMATIC LOCOMOTION.

FEBRUARY 15th, 1898.

DIARY OF FORTHCOMING EVENTS.

Notices to be included under this heading should reach the Office not later than the 12th of each month.

[*For full programme and proceedings of the Self-Propelled Traffic Association, see p.* 189.]

1898.	
Feb. 18 to 26..	Manchester Cycle Show.
March 6 and 7	Marseilles and Nice Race (organised by *La France Automobile*).
March 7 ..	Automobile Club of Great Britain. Second House Dinner at 7.30. To be followed by a discussion on "The Bearing of Past Invention on Future Motor-Car Design."
March 10 ..	Nice—Puget—Theuiers Motor-Cycle Race.
April 24 ..	Paris Motocycle Critérium.
May 2, 9, 16, 23	Society of Arts Cantor Lectures—"Electric Traction," by Prof. Carus Wilson.
May 24 ..	Self-Propelled Traffic Association (Liverpool Centre) Heavy Vehicle Trials.
May 25 ..	"Concours de Fiacres," Paris. Organised by the Automobile Club of France.
June 10 to 25..	Motor-Vehicle Exhibition, Paris. Automobile Club of France. Sections—(*a*) Automotor vehicles which have given proof of their practical efficiency; (*b*) Industries connected with automobilism; (*c*) Motors adapted for automotors; (*d*) Vehicles adapted for automotors.
June 8.. ..	Concours of the Automobile Club Belge.
July 3 to 11 ..	Race from Paris to Amsterdam, under the auspices of the Automobile Club of France.
1899	Race from Paris to St. Petersburg, under the auspices of the Automobile Club of France.
1900	Paris International Exhibition — Great Display of Automotor-Vehicles and Allied Trades.

ANSWERS TO CORRESPONDENTS.

H. P. Fernald (Cheltenham).—Apply to Messrs. Toward, Newcastle-on-Tyne; and to the Liquid Fuel Company, of Cowes, Isle of Wight; also to Messrs. Coulthard and Co., of Preston. Each of these firms can supply your requirements.

L. (New Forest).—(*a*) For steam—Liquid Fuel Engineering Company, East Cowes, Isle of Wight; Lancashire Steam-Motor Company, Leyland, Lancs.; Atkinson and Philipson, 27, Pilgrim Street, Newcastle-on-Tyne. (*b*) Electricity—Elieson Lamina Accumulator Company (Limited), 4, Greenland Place, Camden Town, N.W.; Carl Oppermann, 2, Wynyatt Street, Clerkenwell, E.C.

G. H. E. W. (Rugby).—We have forwarded your letter to Messrs. Bolling and Lowe as desired. The address is 2, Laurence Pountney Hill, E.C.

J. B. (Rudgwick).—The address is Hunter and Co., Eastdown Works, Lewisham.

J. Garner (Burnley).—Book sent as desired. We hope to give fuller details later on in regard to the motor you mention, which, as you say, looks to us like a good thing. The address is given above.

H. C. (Dukinfield).—We have a few copies of Vol. I still left, bound complete, one guinea net. The rest of the back numbers can be supplied you at 7*d.* per copy, post free.

THE LOCOMOTIVES ON HIGHWAYS ACT.

The more we see of the practical working of this Act, the more convinced are we of its need for amendment, and this opinion is, we know, shared by automobilists throughout the country. That it should have been necessary at all to pass such a measure is by no means flattering to our national vanity. We are so accustomed to speak of ourselves as a "practical people" and to extol our truly British virtue of "common sense," as though no other people in the world possessed either practical knowledge of things or common sense. We have enjoyed a long period of profound peace for the last 80 years. France, Germany, Austria, and Russia have during that time been torn and ravaged with either wars or revolutions, and yet those who have gone into the question will tell us that the science and practice of mechanics is more advanced in Germany and France than in this country. The Iron and Steel Commission that visited Germany in order to report upon that industry came back with some really startling information. Not many months ago a deputation from Manchester also visited Germany while labouring under the truly insular idea that *they* had nothing to learn about machinery and that Manchester was the natural home of high-class work. This deputation went, and returned, literally, sadder and wiser men; they reported that Germany had nothing to learn from England as regards machinery. As our columns bear witness, we report whatever progress is being made in automobilism, but we have to confess that the more substantial advances in the subject are mainly of German or French origin.

On the Continent automobilism is encouraged by the State and by public opinion—not for any academic idea but for the truly practical reason that it means cheap transport, and so it happens that we are flooded with cheap foreign goods, and we suffer this gladly because we are *not* a practical people, and so we cling to the horse, although the horseless vehicle has been in existence for nearly a century in a fairly perfected form. We pass an Act which is the wonder and surprise of every educated foreigner. In this precious measure we have carefully and conscientiously made the way of the automobilist needlessly hard. We lose sight entirely of the many advantages to be derived from cheap transport, but provide ample facilities whereby local authorities can, if so minded, greatly prejudice the use of motor-vehicles. While we have taken very good care that motor-vehicles shall fulfil certain prescribed conditions, we have omitted to require that local authorities shall maintain their roads in such repair as to permit them to be used by automobilists.

At present each little commune does that which is right in its own eyes, and hence, except in the larger towns, the roads are almost left to repair themselves. Of course, local authorities will protest vigorously against anything which tends to increase their rates, but once they see—and it is so difficult to make them see—that the improvement in the roads will mean more trade, we feel convinced that an improvement would be effected. We think that the Self-Propelled Traffic Association and the Automobile Club might well take up this matter. A serious anomaly, in our mind, is that very great power is given to the Local Government Board as regards the motor-vehicles, but they have no authority as regards the roads nor over ordinary vehicles. Since no vehicle is of use unless it is worked on a suitable road, and since there must be some central authority, it would seem more logical to place all vehicles and all roads under one supreme authority. We doubt, however, that local bodies will ever consent to any diminution of their control over their roads.

The principle adopted in the Act, of placing large legislative powers—because, after all, this is what they amount to—in the hands of the Local Government Board is open to very grave objection. The Act is practically a permission to the Local Government Board to make what regulations that body thinks fit. Theoretically the Local Government Board is, of course, like all governing bodies, amenable to Parliament; practically it is an *imperium in imperio*, and, like the War Office, follows out its own line of policy independent of the House of Commons. The public, in fact, can exercise but little control over it.

It seems to us that any amendment of the Act should be in the direction of strictly limiting the powers of the Local Government Board to matters of administration. It does not seem advisable that a departmental body should have the power of making regulations which may have the effect of placing automotor vehicles at a disadvantage as compared with ordinary ones. All that we can ask for is a fair field and no favour. No privileges are sought for by automobilists, but, on the other hand, it is not just that there should be any discrimination against them. That local authorities are, in some cases, not indisposed to adopt an unjudicial attitude is shown by the attempt on the part of the Warwickshire authorities to impose a regulation upon automobilists at once unjust and impolitic. Certainly the attempt failed, but what guarantee have we that similar attempts may not be more successful?

The Act should also cast upon local bodies the duty of maintaining the roads in a condition suitable for heavy traction. A specified degree of hardness should be decided upon, that is, the roads should be capable of carrying a weight of not less than 5 tons per square foot. In other respects, too, the Act requires amendment, but we shall deal with other points in due course.

OBSERVATIONS ON THE ENGINEERS' STRIKE.

At length, after a seven months' contest, the disastrous strike and lock-out in the engineering industry has terminated in the only way possible, by the total defeat of the employés. As is well known, this strike arose out of the demand by the hands for a 48-hours' week. This was flatly refused by the employers, who were not sorry of the opportunity afforded them of settling, once for all, many other differences. The hands, as represented by their trades union, the Amalgamated Society of Engineers, had for a long time past been gradually encroaching upon what most people consider the natural and necessary rights of the employers. The men had limited the number of apprentices; they fixed the output of machines; they inaugurated a system of levelling down, whereby the best workman had to work only as well as the most indifferent or lazy. They also interfered in the management, and endeavoured in every way to prevent the employment of non-union labour, while strictly conserving what they considered to be the rights of their so-called skilled labour. In short, the policy of the men was to take all control out of the masters' hands, and run the shops on Socialistic principles—admirable in every way from the men's point of view, but distinctly disadvantageous from that of the masters. As stated, these encroachments culminated in the demand for a 48-hours' week with 54 hours' pay. Of course, there was no lack of soft-minded persons, ranging from bishops downwards, who wished to arbitrate on these grotesque and impossible demands. The result we all know.

This strike has involved some 70,000 so-called skilled mechanics. It has cost them, their families, other unions, and the working class generally not less than £4,680,000, while the employers have lost no less than £5,696,000. The total loss is £10,376,000. We say loss. If, as we suspect, this strike will produce federations of employers, and so ensure industrial peace, then this £10,000,000 is a cheap price to pay. In any case this strike must have very far-reaching consequences. The defeat of one of the most powerful and wealthy trades unions in the world in a fair and square fight marks, in our opinion, the commencement of the decadence of militant Socialistic trades unionism as a national force, and no one sensible of the modern conditions of this country's supremacy in the markets of the world will for one moment regret that this should be so. As is well known, the Amalgamated Society of Engineers made an attempt to put into practice doctrines which, good in themselves, *quâ* doctrines, are as yet impossible of realisation in the present state of our society. Human nature being what it is, and not, as we gather, appreciably changing through the centuries, is not yet capable of assimilating the Sermon on the Mount or the more later teachings of Compte and Marx. So long as—and we think this will obtain for a very, very long time yet—profit is the incentive of the employer, he will require and insist upon having full and supreme control over his business. The arcadian state of things desired by the Amalgamated Society of Engineers and others would be possible no doubt if there was no trade competition, no international competition, no danger in losing a market, no particular necessity of creating one, no danger of foreign aggression or war, and, therefore, no risk of famine. Who would not like to live in the comfortable knowledge that a good living can be assured with but little mental toil or anxiety, but that after the day's work of eight hours one could spend the remainder in intellectual pursuits, in visiting municipal museums, the municipal music-halls, or participating in municipal cricket and football matches, and even witnessing municipal horse races, conducted, of course, under strictly moral conditions?

No one will, we think, blame any body of men—whether these be so-called "working men" or men who live by mental toil—for endeavouring to get all they can for their labour. Unfortunately we cannot—at least, at present—compel any person to be an employer, and we also have the other humiliating fact that the employer is a selfish person greedy for profit; but we do not know that his greed is one bit more mischievous or blindly selfish than that of the typical working man. If the former wants the maximum of profit, the latter exhibits an equally selfish but perfectly natural desire to obtain the maximum of wages or its equivalent. If the prices of work and wages do not enable the greedy, selfish employer to make a living, and put by something in the savings bank for his old age—or, at least, to contribute regularly to, say, an employers' sick and burial club—he also goes on strike and shuts up the shop. In short, unenlightened selfishness in the disguise of humane Socialism was the cause of the late strike. It was not because of this, however, that the strike failed. The public at large would, with its usual sham humanity, have witnessed the decline of the engineering or any trade with pleasure, or at least equanimity, so long as the "toilers" or the "masses" had "opportunities for intellectual recreation and improvement," *pace* the *Daily Chronicle* and other papers after that kind. What prolonged the strike and eventually determined the event was the trades unionism of the employers. Many will remember the anæmic and amœbic state of the employers some 10 years ago, especially of those engaged in the shipping industry. The seamen formed a powerful and autocratic trades union; the shipowners formed the Shipping Federation, with what results we all know. Where is the "Amalgamated Union of Seamen and Firemen" now? Why, tenanting a few back rooms in a back street of the remote East End of London; its funds have gone, its prestige also, its leaders are discredited, and the seamen, to a man nearly, are in the Shipping Federation benefit scheme. The seamen's trades union is utterly and hopelessly broken, never to exist again as before. Similarly we have had the engineers' trades union bringing into existence and opposing the most powerful trades union of employers the world has ever seen. The Employers' Federation controlled, and does still, no small portion of the wealth of the country. Its leaders are educated and intellectual men; its resources and influence are almost illimitable. How, then, can any body of manual workers, for the most part individually of small intellectual calibre and of equally small means, think to maintain a successful contest with such a body? The attempt has been made, and has ended, as was foreseen and as could not otherwise happen, in the most complete defeat of the Amalgamated Society of Engineers. This union is in a similar predicament to the Seamen's Union. Its funds are exhausted, its influence gone, and its leaders discredited.

The strike was marked by some curious features. There were, of course, the usual attempts to "arbitrate," when really there was nothing upon which to arbitrate. There is a precious and typical piece of modern legislation providing for arbitration and conciliation—an utterly absurd and, as the event has proved, useless measure. Mr. Ritchie, the President of the Board of Trade, essayed to "arbitrate and conciliate," but, after a futile attempt, wisely withdrew to foreign parts and hedged discreetly in his utterances. It was curious, too, and not a little amusing, to note the behaviour of public men during the strike. If ever there was a time when the people concerned wanted a leader who would stand forth undismayed, and tell those misguided engineers that their action was foolish and was bound to result disastrously, it was during this strike. No one appeared. A few public men uttered some platitudinous drivel, such as: "they deplored the present lamentable dispute," or piously wished "that wiser counsels would prevail," and so on; others carefully kept out of the way and sent subscriptions—they feared for their popularity, and with reason. There will be many changes among these M.P.'s at the next general election. The attitude of the Press was no less curious. A few papers, such as the *Times*, *Standard*, and some others, took a decided and firm line from the first, and did much to convince the men of the utterly hopeless nature of their demands. The best service was, however, rendered by our contemporary, *Engineering*, which in a series of well written and masterly essays, reviewed the whole progress of modern trades unionism and the effect of the latter upon our productive capabilities. We trust that these valuable papers will be reprinted and circulated wherever working men congregate. The banal attitude of the *Daily Telegraph* needs little remark. The pandering of that journal to "the man in the street" is too well known to require comment. The *Daily Chronicle*, as all can imagine, especially distinguished itself. In the early days of the strike the *Daily Chronicle* prophesied a speedy success for the men, and prepared to celebrate the event in pæans of joy. The sacred banner of "labor" (*sic*) was duly wagged, and copious streams of diluted Socialistic ink and twaddle flowed from the pens of the staff. As matters progressed, the *Daily Chronicle* became suspicious, then doubtful, then frankly pessimistic, and, finally, it indulged in hysterical wails of despair for the cause of "labor," and had to confess that it had again wrongly gauged popular feeling. In the provinces, where working men take some interest in local politics and seem to exercise more political power than do those of London, and where newspaper competition is very keen, the newspapers, as a rule, maintained an attitude of what they are fond of terming "judicial reserve"—not a manly, not an exalted attitude to adopt, but, under the circumstances, an eminently prudent one. Many newspapers and many members of Parliament will, we think, have to seriously reconsider their politics. As one consequence of this strike, opinions on industrial questions range themselves into two distinct groups, clearly demarcated. Every candidate for public office in future—from a beadle to a guardian and from a member of a School Board to a Cabinet Minister—will have to declare whether he believes in the principles underlying and governing the Employers' Federation or those of Modern Trades Unionism, also somewhat euphoniously called Collectivism, or Progressive Legislation on Industrial Subjects. The one means free trade and the right to conduct one's own business in one's own way, and also the right of an employer and an employé to make what bargain they please as regards hours and price of work; the other means a crude and reactionary form of protection and restriction of output, and is an insidious form of tyranny both to employers and employed. Those who have, whether capital, brains, or handicraft are required to share the control of what they have with those who have not or who have but little. There can be no compromise in these conflicting principles. As is well-known, a prominent employer lately hedged on this matter and so lost his election to a North country seat. If one of the effects of the strike is to clear the air on these matters much good will result. This is essentially the age of compromise, not only in politics, but in the principles which underlie them. Not a few thoughtful people see in this love of compromise-in-everything-policy a decadence in our national spirit. Be that as it may. That it is possible to compromise on such conflicting principles as mentioned seems to us impossible. Parliament will no doubt essay the task, but the faith in the merits of Parliament is diminishing rapidly. As the Bishop of London is reported to have said lately: "It took 700 years to produce our Parliament, and what could be more deplorable than that which we now behold?" An opinion which we cordially endorse.

In one special respect this strike has been unusually interesting and instructive, in that it indicates an advance in civilisation. In the Middle Ages such a dispute spread over such a wide area would have resulted in civil war. In the early part of the present century it would have meant riots and the destruction of property. The military would have been requisitioned to keep order, and, as has been the case on more than one occasion, the streets of many of our provincial towns would have been like small battle-fields. The late strike — foolish and fatuous as it was, and entailing as it did much suffering—was conducted by the workers with a moderation and obedience to the law which cannot be too highly commended. Cases of violence and intimidation were very few. Such good conduct was the admiration and envy of all civilised governments. Even he of the "mailed fist" was impressed. Costly as has been this strike, it has taught the working man some useful and needed lessons, one of the most important being that every man in a really free country has a natural right to learn any trade, and to get his living by the pursuit of any trade, and to sell his labour for any price he cares to accept. Lastly, in all callings, no matter what, the natural law holds, "the tools to him that can handle them." G. H. L.

TREMENDOUS EXCITEMENT IN FLEET STREET.

A FEW evenings back an electric cab was proceeding down Fleet Street with a fare when, owing to a defect in the rear axle, the cab came to a standstill and it was found impossible to move it. It was placed alongside the pavement at Shoe Lane, the fare alighted, and the driver went for assistance. This trivial accident soon became noised abroad. The newspaper offices belched forth a crowd of fervid and curious journalists, who surrounded the cab and began forthwith to take copious notes. The cab being an automotor-vehicle seemingly excited the feelings of these journalists to a startling degree; many were overcome (with "Scotch"), and others manifested considerable emotion. War correspondents at last found something, so they thought, worth describing. A stranger attracted by the excited and surging crowd asked a scribe what was the matter, the scribe replied: "A motor-car has broken down and we are all very much shocked, because accidents never occur to horse-drawn vehicles." The news of the mishap had caused a big crowd to assemble, and the police had to take extra precautions. In order that a full, true, and descriptive account of this terrible mishap should be transmitted with the least delay to the ends of the earth, a telegram was sent to the Postmaster-General, who gave permission to run a temporary wire from the Strand Post Office to the private bar of a well-known "hotel" near Wine Office Court—much resorted to by journalists. On the bar of this "hotel" a Morse sounder and transmitter were fixed. Special correspondents of the *Daily Mail*, the *Morning*, and other papers after that kind, distinguished for their unfailing integrity and veracity, kept watch and watch near the scene of this awful cab disaster, retiring at intervals to the before-mentioned "hotel" to report to the man in charge of the wire, who bore a striking resemblance to the chief reporter of the "Daily Gusher," a paper well known for its sensationalism, and also to obtain spirituous stimulus to enable them to withstand the awful mental strain. Nothing, however, occurred, and next morning the cab was quietly repaired and taken away. In the meantime some really thrilling descriptions were being set up by the compositors. So important did the *Daily Telegraph* consider the affair that, not content with a harrowing and mendacious account, they actually had a leading article on it. The leader bears evident signs of having been written under very great emotion. The writer's mental excitement must have been terrible. It was no doubt the electrical cab that caused it. He and the other scribes who so distinguished themselves on that fatal night have our deepest sympathy, and we trust that electrical cabs will never again be the cause of such an amount of exaggeration and nonsense. A few days before this accident occurred, a horse attached to a trolley in a street at Newcastle took fright and ran away. It collided with a tram-car; one girl was killed on the spot, and four persons injured, and yet not one of the daily papers supply a really thrilling description of the accident; neither does the *Daily Telegraph* give a leading article about it.

Referring to this trivial cab accident, the *Electrical Review* says: —"The daily Press would seem to be short of matter just now judging by the amount of attention given to the mishap with an electric cab in Fleet Street. It is not altogether the right thing to prejudice the general public against these vehicles before they have had a fair trial, but this seems a very likely result of some of the high-falutin and imaginative accounts which have been printed regarding what is officially termed the skidding of the hind wheels. The only damage to the vehicle seems to be the straining of one of these wheels, and the following day the cab was working as usual. The daily sensationalist made it appear that the cab was smashed to pieces, and half of Fleet Street ploughed up."

THE THAMES PASSENGER AUTOMOBILES.

In the Automotor for November we discussed the existing river service and pointed out its deficiencies. We also made several suggestions for the design of new vessels for this service. We now learn that many of these suggestions are being adopted in three new vessels for the Thames river traffic now being built by the Thames Iron and Shipbuilding Company, at Blackwall, and these vessels are each 120 feet long, and are now in an advanced stage of completion; they are being fitted with water-tube boilers. Elaborate accommodation has been provided for passengers, and the scheme of construction followed will allow of passengers being able to use the entire upper deck, a large section of which in the old boats has been taken up by the boilers and engine-room skylight. It is understood that electricity will be used for lighting purposes. The boats will have a speed considerably in advance of those that carried on the service in previous years.

COMPARISON BETWEEN HORSE-KEEP AND MOTOR-KEEP.

M. D. Creuzan, President de l'Automobile Bordelais, writing to *La France Automobile*, makes the following interesting comparison:—

Daily Keep of Two Horses.

	Francs.
Food, hay, &c.	5·0
Litter	1·0
Smith	0·30
Harness	0·50
Rent of stable	0·50
Veterinary, &c.; repairs to carriage, stable, and harness	1·15
Total	8·45

Daily Cost of an Automotor Vehicle.

Daily journey, 30 miles.

	Francs.
6 litres petrol	2·10
Oil waste, &c.	0·15
Repairs	1·00
Use of rubber tyres, &c.	1·25
Total	4·50

Daily saving by using an automotor, 3·55 francs.

If the reader will turn back to the Automotor for October, and read up the article on "Kelvin's Law of Economy," and apply the above figures or others to any given case, a most instructive and accurate conclusion will be reached, viz., that *it is always much cheaper to use an automotor vehicle.*

NOTES OF THE MONTH.

The Church Army is endeavouring to raise a sum of £400 wherewith to purchase an automotor vehicle for use in country districts.

The Hackney Vestry has deferred for six months the further consideration of the proposal to consider the advisability of adopting carts and vans driven by electrical or other automatic motors.

On January 21st, Mr. William Angus, J.P., of Newcastle-on-Tyne, was elected president, and Mr. Andrew W. Barr, secretary, of the Institute of British Carriage Manufacturers for the ensuing year.

The Watt Memorial Lecture, given at Greenock on the anniversary of the great engineer's birth, will this year be delivered by Professor Thorpe. The subject will be "James Watt and the Discovery of the Composition of Water."

The motor vehicle is becoming a favourite mode of conveyance with members of "the Profession." La Belle Magicienne Company have two in which Mdlle. Patrice and her suite travel from town to town, and so prevent the poor railway directors from earning a few pounds.

It is said that some American capitalists have been so impressed with the utility and success of automotor vehicles for postal work that they have formed a Company, called the Motor-Wagon Company, with a capital of 5,000,000 francs, to construct postal automotor vehicles.

The Essex County Council have passed a resolution strongly in favour of the construction of a light railway for Ongar, Dunmow, and Yeldham. The proposed line will be 27 miles in length, and will serve a purely agricultural district which is greatly in need of railway facilities.

From the *Madras Standard* we learn that a motor-car has arrived in Allahabad, and achieves a high speed, and appears to run smoothly, and is a comfortable carriage. Babu Veru Madhava Das, who is exhibiting it to the public, is, it is stated, trying to introduce motor-cars into that country.

The production of aluminium in the United States in 1897 amounted to 2,000 short tons, or 4,000,000 lbs., against 1,300,000 lbs. in 1896. This was entirely the production of the Pittsburgh Reduction Company, which continues to control the manufacture of this metal in the United States.

In a recent issue, *Country Life* says:—"Motor-cars and bicycles have played havoc with the price of certain classes of horses, such as light hackneys and roadsters, but Shires seem to keep up their price well. There appears to be a constant demand for heavy draught horses, at good and remunerative prices."

During 1897, exclusive of warships, 591 vessels of 952,486 tons gross—viz., 545 steamers of 924,382 tons, and 46 sailing vessels of 28,104 tons—have been launched in the United Kingdom. The warships launched at both Government and private yards amount to 48, of 95,465 tons displacement. The total output of the United Kingdom for the year has, therefore, been 639 vessels of 1,047,951 tons, a decrease of 207,000 tons as compared with 1896.

THE record life for a tramway rope is believed to have been attained by a special crucible steel rope made by Messrs. George Craddock and Co. It worked for 90 weeks and two days, or 111,712 cable miles, on the Bourke Street line of the Melbourne Tramway and Omnibus Company. The total length is 18,000 feet, and its circumference 3⅝ inches.

ABOUT 5,086 tons of horseshoes were exported from Norway in 1896, as against 5,319 tons in 1895, almost the entire quantity being from Christiania. Great Britain and France, where shoes are used not only for horses, but also for donkeys and oxen employed as beasts of burden, divided almost the whole exportation between them in about equal quantities.

IN the shops of the Russian Locomotive Company in Charkow the first locomotive has recently been finished, a fact which may be of some interest, because the said firm is the first of its kind in Russia that is working almost exclusively with Russian capital, has been built and is managed by Russian engineers, and has among its workmen and employés not a single foreigner. The Company is reported to have got the supply of 488 locomotives for the Russian State Railways, to be delivered within the next six years.

A NEW use for sawdust has been discovered, in that it can be employed in the manufacture of calcium carbide, the chief source of acetylene gas, under the process patented by Professor Wilson, of St. Catherine's, Ontario. By this process, says an American contemporary, all refuse from saw-mills can be rapidly converted into carbon. This is powdered and mixed in equal quantity with limestone, and the mixture then subjected for ten hours to an electrical current strong enough to boil iron. The result is calcium carbide. The mass is broken into small lumps, and in that form is shipped to consumers.

THE materials required to make a London and North Western locomotive have recently been totalled up, and the quantities of each work out as follows :—Coals, 57½ tons ; steel scrap, 28 tons ; pig iron, 24 tons ; Swedish iron, 6½ tons ; copper, 5 tons ; coke, 4½ tons ; spiegel, 2¾ tons ; cast-iron scrap, 1½ tons ; limestone, 18 cwt. ; tin, 4¾ cwt. ; manganese iron, 1 cwt. ; red ore, 1 cwt. ; lead, 83 lbs. ; zinc, 76 lbs. ; phosphor bronze, 70 lbs. ; chrome, 30 lbs. ; aluminium, 13 lbs. ; antimony, 4 lbs. Although the component materials weigh in round figures about 140 tons, the finished locomotive only scales about 45 tons.

SAYS the *Midland Daily Telegraph* :—" I learn that the Local Government Board, being appealed to by the County Council of Warwick with regard to autocars, reject the idea that they should be registered and numbered, as this requirement would have a tendency to seriously interfere with the motor-car industry." Bravo, L.G.B. A new industry which, owing to its extreme youth, is essentially timid and shy, does not want hampering about with all manner of restrictions, or it will give us the go-by. Autocars are subject to quite sufficient drawbacks already. There is no need to quite frighten and harass them off the road."

AN important step is being taken to establish a service of motor-cars in the West of Scotland. A Company is being formed, the object of which is to provide motor-car service and hiring establishments in Scotland and elsewhere. The Company have ordered 12 cars as a commencement, and to start them in regular brake service in such popular watering-places as Dunoon, Rothesay, Largs, Millport, and other suitable districts. The cars will each carry about eight persons. It is intended to establish runs of about four miles each way, the journey being performed within an hour. The North of Scotland is also moving in the matter, The Links and Parks Committee of the Aberdeen Town Council have recently received a letter from Messrs. Stirling (Limited), Hamilton, offering to provide a service of motor-cars from the centre of the city to the bathing-station at the sea-beach, on condition that the Town Council guaranteed that they would not start any other service for at least five years. The committee were not prepared to give such a guarantee, but indicated their willingness to allow the Company every facility for running cars, and a shed at the beach for the storage of the vehicles.

CONTINENTAL NOTES.

AT the works of M. Thomas 100 vehicles are being constructed.

MM. TH. CAMBIER ET CIE. are at present constructing 50 motor-vehicles.

THE firm of M. E. Delahaye has been converted into a company under the title of Delahaye et Cie.

THE Company working the Krieger patents for electrical motor-vehicles has a capital of 4,000,000 francs.

THE Société des Ateliers Germain has acquired from Madame Levassor the patents of the Daimler "Phœnix" motor, and has commenced operations at Monceau sur Sambre.

IN order to lessen or avoid the smell given off by automotors using petrol, M. Chevalet proposes to affix a kind of scrubber to the exhaust. According to experiments, considerable success has been achieved.

IN order to avoid the disagreeable smell given off by acetylene lamps, a writer in *La France Automobile* recommends placing a few drops of turpentine essence (essence de térébenthine) in the lamp; this is said to effectually destroy the objectionable odour.

THE death is announced from Paris, at the age of 71, of M. Ernest Bazin, the inventor of the roller boat, which was described in our columns last May. We predicted failure for this vessel, and our anticipations were realised. M. Bazin was also the inventor of the electric submarine lamp, and a number of mining improvements.

THE Commissioners of the Paris 1890 Exhibition have classed cycles and automobiles with horse-drawn carriages. An absurd thing to do, and about as sensible as classing an Egyptian chariot with an express locomotive. Naturally this stupid mistake has excited intense disgust among automobilists, who threaten to recede from participating in the Exhibition.

A DEPUTATION from the Automobile Club of France has been officially invited to attend the heavy motor-vehicle trials to be held in Liverpool in May next, and the whole of the members of the French Club have also been asked to be present at a banquet which will be given at Liverpool, in honour of the visit of the French automobolists, by Sir David Salomons and the committee of the Liverpool Centre of the Self-Propelled Traffic Association.

IT is said that a powerful French company has addressed a simultaneous request to the Governments of France, Belgium, and Holland for powers to establish a system of electric traction along the navigable highways of the three countries, so as to form an international network extending from the Rhine, through Holland, and as far as Marseilles through the Eastern departments of France, making use, for the purpose, of the navigable highways of the three countries. It is stated that the Banque de Paris et des Pays Bas is interested in the enterprise.

DOINGS OF PUBLIC COMPANIES.

The Manufacture of Motor-Cars.—In *re* Bradbury and Co. (Limited), Oldham.—On the 7th inst., in the Lancashire Chancery Court, a petition was made by Mr. Maberly and Mr. Tweedale, on behalf of Messrs. Bradbury and Co. (Limited), bassinette manufacturers, Oldham, to have the articles of association amended to enable the Company to extend their business to the manufacture of bicycles, motor-cars, &c. The Vice-Chancellor allowed the petition.

The Electric Metal Working Syndicate (Limited).—We are informed that Messrs. Scott, Anderson, and Beit, of Royal Insurance Buildings, Sheffield, have been appointed sole agents for the Voltex process of electric welding, brazing, &c., for the following counties:—Yorkshire (south of a line through Whitby, Northallerton, and Richmond to Kirkby Stephen), together with the entire counties of Lancashire, Nottingham, Derbyshire, Staffordshire, Cheshire, Worcestershire, and Warwickshire.

A Vast Engineering Concern.—The United Ordnance and Engineering Company (Limited) has lately been formed. It is practically a combination of the Fairfield Shipbuilding Company, of the Clyde; Messrs. Easton, Anderson, and Goolden, of Erith; Chas. Cammell and Co, of Sheffield; and Messrs. Schneider et Cie., of Creusôt; the latter world-renowned firm has lately undertaken the manufacture of the well-known Canét ordnance. Messrs. Frith, the well-known steel makers, are also in it. In short, this is probably one of the most powerful and influential commercial concerns in the country. The Armstrong-Whitworth "combine," as the Americans would say, comes first, then the Vickers and Maxim firm, and now the Ordnance and Engineering Company. Each of these firms can undertake the construction of a first-class battleship, including guns and armour, without going outside. On the board of the latter Company we notice the names of Professor Elgar, the designer of the Cunard "Lucania" and "Campania," Mr. Chas. Cammell, the "steel man," and Mr. K. Baynes; while wealth, at any rate, is ensured by Mr. McCalmont, the millionaire. Admiral Nicholson, the late Naval Commander-in-Chief at the Nore, also sits on the board. It is perfectly well known that one of the by no means least important influences which have led to the formation of this and other powerful combinations in mechanical industry has been the necessity of meeting the modern form of aggressive trades unionism. These Companies, with their vast resources and influence, could maintain their positions when, as individual employers, they might be ruined. That the public believe in such combinations as tending to preserve industrial peace is shown by their eagerness to become shareholders.

Hastings Cycle and Motor-Car Company.

The shareholders in this Company met at an adjourned meeting last month. Alderman Glenister, who presided, explained that at the previous meeting a committee of inquiry was appointed to look into the state of the Company, and the first business of that meeting was to receive their report.

Mr. St. John said that the investigations were not quite complete. A firm of valuers had been engaged to carry out an independent valuation which had not yet been completed, and until it was finished it was impossible to make a report. He moved that the meeting stand adjourned for 14 days.

The extremely vague report of the Company's "consulting engineers" can hardly inspire confidence.

London Electrical Cab Company.

On January 25th an issue was announced by the London Electrical Cab Company (Limited) of the balance of 86,388 £1 shares at a premium of 2*s*. 6*d*. per share. Of the total share capital of £150,000, 63,612 shares have already been issued, and the prospectus states that, by arrangement with the vendors, the proceeds of two-thirds of the shares already issued were retained for working capital, and the balance of one-third only was paid to the vendors on account of the agreed purchase price, namely £50,000. The proceeds of this issue are to be similarly dealt with, so that the working capital will continue to be two-thirds of the total share capital issued. The Company was formed in November, 1896, and it is stated that although the outlay up to date includes the cost of altering and adapting the buildings in Juxon Street, Lambeth; fitting up the same with electrical plant, machinery, &c.; also all preliminary expenses and the cost of the cabs now on the streets, and parts of further cabs, the Company still have at their bankers nearly half the working capital received. It is pointed out that a much larger number of cabs might have been placed upon the streets within the same period, but in the interests of the Company it was decided to first practically test a smaller number, and that it is with the object of still further increasing the number of the Company's vehicles that this issue is made.

We think it would have been only fair to the shareholders to have given some of the working figures of the last few months, together with a report showing how the accumulators and the Lundell motor have stood the strain required of them.

A Great Horseless Carriage Problem.

The *nominal* market value of Great Horseless Carriage Company's £10 shares is at present 2*s*. 6*d*. Under the reconstruction scheme now going on this 2*s*. 6*d*. will therefore secure:—

Six Motor Manufacturing Company's £1 shares, 17*s*. paid;
Four British Motor Syndicate Preferred £1 shares, 17*s*. paid; and
£1 British Motor Syndicate Debenture.

Find the real value of each class of *security*—save the mark—taking into consideration the liability of 30*s*. accompanying the half-crown investment.

New Issue.

The Electric and General Investment Company (Limited) offered on February 8th for subscription, on behalf of the British Electric Traction Company (Limited), 10,000 six per cent. cumulative preference shares of £10 each of the latter Company at £12 10*s*. per share. The British Electric Traction Company was formed in 1896 to acquire the business of the British Electric Traction (Pioneer) Company, and to develop electric traction in the United Kingdom and elsewhere, and is now engaged in furthering its objects in connection with a number of tramways and light railways in various parts of the kingdom. The authorised capital of the Company is £600,000, divided into 30,000 preference and 30,000 ordinary shares of £10 each. The whole of the ordinary shares have been subscribed and paid up in full, and the present is the first issue of preference shares.

New Companies Registered.

[Under this heading we give a full list of new Companies registered which take power to make, deal, or become interested in any manner in automotor vehicles.]

	Capital.
Abel Morrall, Ld. (Studley and Redditch)	£50,000
Austen's Patent Wheel-Making Machine, Ld.	75,000
Brayton Oil-Motor Co., Ld.	100,000
Co-operative Cycle Manufacturing Co., Ld.	10,000
Cycles, Ld.	10,000
Delacroix Motor Syndicate, Ld.	60,000
Edward Preston and Sons, Ld. (21, Whittall Street, Birmingham)	50,000
Endurance Motor Co., Ld. (18, Hertford Street, Coventry)	1,000
Hoffmann Manufacturing Co., Ld.	100,000
Home and Colonial Cycle Supply Co., Ld.	5,000
Langdon Davies Electric-Motor Co., Ld.	70,000
Madeloic Motor-Carriage Co., Ld. (Scotch Co.)	25,000
Maxim Autocar Syndicate, Ld.	5,000
Motor-Carriage Supply Co., Ld.	12,000
Motor Manufacturing Co., Ld.	300,000
New Raleigh Cycle Co. (Spain), Ld...	100,000
New Rock Cycle Manufacturing Co., Ld. (Sheffield) ..	10,000
Northern Counties Electric and Motor Co., Ld.	10,000
Pneumatic Hub Syndicate, Ld. (Scotch Co.)	12,000
Saxton and Davies, Ld.	10,000
Speed Indicator Co., Ld.	10,000
Wolverhampton Tyre Syndicate, Ld.	1,000

CORRESPONDENCE.

*** *We do not hold ourselves responsible for opinions expressed by our Correspondents.*

*** *The name and address of the writer (not necessarily for publication)* MUST *in all cases accompany letters intended for insertion or containing queries.*

ELECTRICAL ROAD TRACTION.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—The electrical cab appears to be a complete success, and very great credit is due to Mr. Bersoy and others, but the fact must not be overlooked that circumstances have been favourable to it. They have mainly been tried on the smooth thoroughfares of London, and there has been no snow to contend with. On country roads, which often vary from bad to worse, and where ultimately an enormous development in electrical traction will take place, the jolting and straining of machinery and serious waste of tractive power caused by road inequalities and obstacles will have to be considered; and what is now to the motor-car enthusiast comparatively trivial, will be of financial importance when our great road traction companies are formed. To overcome these difficulties no springs can ever compete with large pneumatic tyres, or with pneumatic wheels. The pneumatic tyres hitherto tried for heavy motor-cars have had too restricted an air space, and also required a dangerously high air pressure, which nullified their power of absorbing road obstacles. No doubt, if they are made very large they may appear ugly at first, but the public soon grow accustomed to novelty in form; the appearance of the pneumatic cycle tyre was against it when it was first introduced, but now a cycle looks strange without one. With respect to pneumatic wheels, Mr. Radcliffe Ward and other electrical engineers have proved that, as now made, they can carry the heaviest weights at the same air-pressure as an ordinary cycle tyre.—Yours truly, "Progress."

January 22nd, 1898.

[We are obliged for the sensible remarks contained in the above letter. We must point out, however, that the London electrical cabs are not designed for other than very good roads. So far they are very efficient. For ordinary roads, under such conditions as mentioned by our correspondent, they would hardly answer, as the power would soon exhaust the storage. As regards tyres of the pneumatic type, these are, after all, but an indifferent contrivance. Much can be done in perfecting spring suspension.—Ed.]

INQUIRY FOR STEAM TRACTOR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I would be very glad if you could inform me where to buy a horseless motor to drive a small tramcar a distance of 11 miles daily. It may be by electricity, oil, or gas. The car is to carry 10 passengers. There is on the line a gradient of $1\frac{1}{4}$ per cent.

Please send the prices and catalogues of the motor for 1, 2, 3, and 4 H.P.—I remain, yours truly, O. Cavour,

Resident Engineer of the Leopoldina Railway.

[Makers of motors will no doubt notice the above.—Ed.]

INSTRUCTION IN DRIVING STEAM TRACTORS.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—Having been a reader of your Journal from No. 1, and being interested in road locomotion, I should like to learn to drive a steam motor wagon, such as the one illustrated in the December number of your Journal, or any similar one. Could you kindly tell me how I could learn? I am at present steering traction engine.

Wishing your paper and efforts every success,—I am, yours faithfully, E. J. Walter.

Corton Denham, Sherborne, Dorset.

[We would suggest that you place yourself in communication with makers of steam tractors, and offer your services; there is really little to learn.—Ed.]

THE PRICE OF THE DAIMLER MOTOR.

To the Editor of The Automotor and Horseless Vehicle Journal.

Sir,—I shall be obliged if you will give me the names and addresses of different concerns who use the Daimler motors in their auto-cars. I am contemplating buying a car, and am of opinion that the Daimler are most practicable; and the only question is, who can supply it cheapest, as the price, as far as my experience teaches me, is their chief drawback. Your attention in correspondents' column, or by post, will oblige,—Yours truly, Edgar Wrightson.

The Nine Elms, Hinckley, Birmingham.

January 5th, 1898.

[We really have no such information at our disposal. We should say that if the Daimler Company's price is too high, it is hardly likely that the price asked by their licensees would be lower.—Ed.]

PHOTOGRAPHS AND PICTURES OF AUTOMOTOR VEHICLES.

À Monsieur le Redacteur Automotor and Horseless Vehicle Journal.

Monsieur,—Je suis chargé par le Comité de l'Automobile Club de France de réunir les photographies et gravures de toutes les voitures automobiles.

Cette collection remontera aux modèles les plus anciens et sera continuée au fur et a mesure des perfectionnements de cette industrie.

Je viens donc vous prier de bien vouloir contribuer à enrichir ces intéressantes recherches, en me faisant parvenir une ou plusieurs photographies ou gravures non collées de chaque type de ces voitures, format 13 × 18 au moins, papier platine de préférence, en mettant au dos votre nom, l'année de la construction et la force du moteur.

Ces documents seront classés par année et collés dans des albums déposés à la bibliothèque de l'Automobile Club. Certains modèles anciens et particulièrement curieux pourront être encadrés, mais pour le moment je ne m'occuperai que des albums.

J'espère, monsieur, que nous aurons le plaisir de recevoir votre collection.

Je vous serai reconnaissant de me faire savoir le plus tôt possible si je puis compter sur ces précieux documents que vous pourrez me faire parvenir à mon domicile, 7, Rue de Greffulhe ou au Cercle.

Si vous possédez en outre des photographies représentant les voitures à l'arrivée des courses, les réunions de Meulan ou d'autres beaux instantanés rappelant des souvenirs d'automobilisme, ils seront également les bienvenus.

En attendant, veuillez agréer, monsieur, l'assurance de mes sentiments distingués.

Raoul Lemoine, Artiste-Lithographe.

Automobile Club de France,
4, Place de l'Opera, Paris.

[We have pleasure in publishing the above request, and make no doubt that those of our readers who have photographs, &c., of automotor vehicles will send them to M. Lemoine—at least, we hope they will, as such a collection as suggested would be of very great value and interest.—Ed.]

Steam Automobile Fire-Engines.—Hull is apparently the first city in Great Britain to recognise the need of automobile fire-engines. This is not due to any municipal enterprise but to the foresight of the North Eastern Railway Company, which has very extensive premises at Hull, and, as the latter is a great timber port, the need for very efficient means of fire extinction is very plain. The new engine, which has already satisfactorily emerged from a series of severe tests, has been made at the North Eastern Railway Company's works at York and will form one of the fire-engines which the Company have at Hull, and there is no doubt that others will soon be built. The engine can travel 15 miles an hour, has been brought to a dead stop half-way down a steep hill, and has been manœuvred with the greatest ease within the limits of a 50-feet turntable.

AUTOMOBILE CLUB OF GREAT BRITAIN.

A General Meeting of members was held at the Club-house, 4, Whitehall Court, London, S.W., on Wednesday, February 9th. The meeting was largely attended, and was presided over by Mr. Roger W. Wallace, Q.C., Chairman of the Committee.

The accounts to December 31st last and the budget for the current year having been approved and passed and the revised rules having been adopted, it was announced that there remained only a limited number of vacancies in the roll of founder members, and that as soon as this had been filled it was proposed to impose an entrance fee and to increase the subscription.

Immediately after the termination of the meeting, the first house dinner took place in the Club dining-room. The dinner was attended by upwards of 100 members and guests, and was presided over by the Right Hon. Lord Suffield, K.C.B., a member.

The following members and guests were present:—The Right Hon. the Earl of Galloway, K.T., the Right Hon. the Lord Justice Clerk of Scotland (Lord Kingsburgh, C.B.), Mr. Roger Wallace, Q.C., Mr. Frederick R. Simms, Messrs. John Allen, A. Fairlie Allingham, Captain Ironside Bax, Messrs. W. Worby Beaumont, M.I.C.E., M.I.M.E., Mr. G. H. Little, C.E., Thomas J. Bennett, Walter C. Bersey, Alfred F. Bird, A. J. Boult, Frank Briggs, E. H. G. Brewster, Hugh Campbell, Herbert C. Capel, T. Clarkson, Charles Cordingley, Captain A. B. Cunningham, Messrs. John Freeman Dyson, Jesse Ellis, H. J. Gully, H. Hewetson, W. W. Hodges, William Bell Ingram, Ernest M. C. Instone, Maurice Jenks, Claude Johnson, F. Shaw Kennedy, J. Henry Knight, S. Howard Lane, Dr. W. W. Leadam, M.D., Mr. A. Ledger, Colonel J. W. Lee, Messrs. Wm. J. Leonard, Jas. W. McManus, J. Melling, C. Harrington Moore, A. F. Mulliner, A. C. Newstead, C. Oppermann, J. W. Parr, B.A., A.I.E.E., G. Foster Pedley, Thos. John Perrett, James Dennis Roots, Captain George D. Sampson, J.P., Messrs. J. Lyons Sampson, Oscar Schölzig, Dr. C. E. Shelley, M.A., M.D., M.R.C.P., Messrs. A. O. Stopes, Henry H. J. Sturmey, Theodore F. S. Tinne, Cecil F. Twist, E. Townsend, Theo. Vasmer, A. J. Walter, A. J. White, C. Grahame White, W. H. Willcox.

The toasts of "Her Majesty the Queen" and "Their Royal Highnesses the Prince and Princess of Wales and the Royal Family" having been proposed by Lord Suffield and honoured, the Right Hon. the Lord Justice Clerk of Scotland proposed the toast of "The Automobile Club of Great Britain." His Lordship referred to the backwardness with which new ideas have always been received by British people, and, as examples, recalled how the people of Sheffield had done their best to keep railways from running through or near their town; how the original inventor of the electric telegraph was implored by his family to give up so quixotic an idea; and how the prejudice against telephones still existed. Lord Kingsburgh pointed out that for this reason it could not be expected that motor-vehicles would come into general favour at a bound, but he avowed that he was certain the huge advantages of the movement would, in time, tell on the natural conservatism of the nation, and that this system of locomotion would become generally adopted for certain purposes. For these reasons his Lordship had every belief in, and wished for, the prosperity of the Club. The toast having been received, Mr. Roger Wallace, Q.C., whose name was coupled with it, replied shortly, as it was his intention to open the discussion which it had been arranged should follow the dinner.

Mr. Wallace proposed the health of Lord Suffield, and a vote of thanks was passed, with acclamation, to his Lordship for acting as chairman. Lord Suffield having replied, the company adjourned to the reception room of the Club, where the discussion on "The Best Means of Promoting the Utility of the Automobile Club" was opened by Mr. Wallace and by Lord Galloway.

Mr. J. Dennis Roots then read the following paper:—

One of the first things that impresses itself upon an intending purchaser of a motor-vehicle and which is at present one of the chief hindrances to the rapid extension of automobilism, is the delay arising from difficulties in the way of the manufacture. The manufacturer of a motor-vehicle has to make practically every part of the vehicle himself; there is hardly any part, however small, except the body and the springs and wooden wheels, if these be used, that he can purchase in this country to save time in manufacture. If steel suspension-wheels of the cycle type are specified, even these he must either make himself or have made specially. In ordinary carriage-building, the builder makes the body and generally purchases the axles of one firm, the wheels of another, and knows where to purchase all the various parts he may require, whether ironmongery or otherwise. In building an ordinary carriage it must be remembered the chief portion is the body; in building a motor-vehicle the body is a very minor part. Given the motor, frame, and wheels, you may fix upon it almost any kind of body you wish. If anyone should wish to make a bicycle, again, he can purchase every part of the machine wholesale and fit his bicycle together himself. The motor-vehicle builder, however, has not only to design every part of the vehicle himself but to make practically every part himself, with those exceptions stated, even to the necessary ball-bearings. Until a week or two ago, when a firm in Birmingham commenced to make the Ackerman jointed axle, this had to be either obtained in Paris or you must make it yourself.

Now I would submit that the Club might make it known to Birmingham firms, for instance, that various parts, such as large ball-bearings, steering and controlling levers, plated or otherwise, balance-gear, rubber-tyred wheels of the cycle type, and other small parts that are used and usable on almost all cars, might be made with advantage to both purchaser and manufacturer. I know it will be urged that this is one of those things that is entirely a question of supply and demand, and this is true up to a certain point, but there is no doubt a real demand now, yet no English firm manufactures them to my knowledge. Facilities of manufacture will be the greatest aid to the industry, will reduce the present comparatively high price of the vehicle, and generally extend automobilism. Representations backed by the weight which such an enlightened body as the Automobile Club confers might be made to a few likely manufacturers. I feel sure that some firms would be convinced of the advisability of being first in the field in what is going to be such an extensive industry.

I hope I am not looking at the subject too much from the manufacturer's point of view, but I would submit that whatever is for the benefit of the manufacturer is also indirectly to the advantage of the public and the purchasers of motor-vehicles. Conducting experiments for the determining of data relative to petrocars and motor-cars appears to me to be an advisable extension of the usefulness of the Automobile Club. One of the first points upon which definite information is required by the engineer is the necessary tractive force in pounds required per ½ ton and per ton of gross weight, for I do not think that the latter would be just double the other. This should be ascertained for iron tyres, for solid rubber, and for pneumatics. Also the tractive force for different kinds of roads, ordinary macadam, country road and London macadam road, for these are not, I am sure, the same thing; the tractive force for the ordinary London macadam would be much higher. I am, of course, not speaking of newly-laid macadam. Then, again, the tractive force for ½ ton and for every additional ½ ton up to 3 tons should be determined for gradients commencing from 1 in 20 up to 1 in 7. Definite data on these points would be very valuable. There is a good deal of conjecture about them. During the discussion on a paper recently read before the Institute of Electrical Engineers, opinions varied as to the tractive force required per ton on the level, between 35 and 65 lbs. Of course the amount would vary for different surfaces.

There are various points which will occur to everyone upon which an authoritative statement would be very useful. Some very wild statements have occasionally been made as to the H.P. necessary for petrocars and other motor-vehicles, but the H.P. is, within certain limits, calculable from the tractive force. Local authorities or surveyors might be requested to give the Club information as to the gradients of the steep hills in their neighbourhood.

Perhaps a few comments on the Local Government Board regulations would not be out of place, as such a body as our Club ought to be in a position to tender suggestions when they are up for revision, as they sooner or later inevitably must be. Admirable as some of these regulations are, there can be no doubt they were made in the dark, when hardly any one in this country, including the framers, had any knowledge of the subject. I will call attention briefly to two points in the regulations. It is provided that if the weight of a light locomotive exceeds 15 cwt. it shall have a tyre of 2½ inches wide. Now, in all probability, whether the vehicle be driven by steam or the explosions of benzoline spirit or of kerosine oil, if the vehicle weighs 15 cwt. then it will not carry much more than 15 cwt. That is 1½ tons total. I have measured the tyres of many vans in London which regularly carry a total of 3 tons, and the tyres are only 2 inches wide. The London omnibus, which weighs 33 cwt. and carries a load of about 2 tons, has a tyre of only 2¼ inches for the back wheels and 2 inches wide for front wheels. The inconvenience of this regulation has been impressed upon me recently very strongly, as in designing a kerosine oil motor-van, I have had to add a wholly needless cwt. to the weight of the van in superfluous width of tyre. My other point—the limit of speed to six miles an hour in any city, town, or village is needlessly hampering, and an almost impossible regulation.

Finally, I would with all deference submit to our Managing Committee that it is seriously restricting the usefulness of the Club in closing it at those times when the busy man is most likely to use it—in the evening. And even the man of leisure is not unlikely to desire to use the Club in the evening at those very times when he will find it closed.

Dr. SHELLEY, of Hertford, commented on the mixture of derivation in many words connected with self-propelled vehicles.

Mr. ARTHUR WALTER suggested that amongst the means of promoting the utility of the Club might be included the following:—(1) That the Club should collect and display pictures and photographs of the various forms of carriages supplied by different manufacturers, together with price lists and information as to how long after the receipt of an order the manufacturer could deliver a carriage; (2) That the Club should obtain and place at the disposal of members maps on which should be indicated the various gradients on the chief roads, notes as to the state of repair of the roads, &c., in order that owners of motor-vehicles might know which roads they might safely travel on and which to avoid; (3) That the Club should continue in the attempt recently inaugurated by it to form the register of competent motor-carriage drivers.

Mr. W. BEAUMONT said that the subject of discussion was the best means of promoting the utility of the Automobile Club. It was hoped that the Club would be recognised as the representative of the great industry in automobile construction and use, which without doubt we were now entering upon. It was desirous that the requirements of automobile employment should in the future be represented by a powerful association, and not, as hitherto, by individuals, whose efforts towards obtaining redress or facilities must remain futile, or nearly so, even though individuals were sometimes influential men. We were entering upon an industry which will again draw attention to the importance of perfection of the many thousands of miles of common roads used in the United Kingdom by about 1,500,000 draught horses, and by those who employ over 500,000 licensed vehicles. In the early part of this century the pressing need for improved communication between the great centres in this country had resulted in the employment of engineers to make a few really good roads, good as compared with any previously existing. The birth and rapid extension of railways made further attention to these main roads of communication for the time less necessary, the relief by railways being so great that for generations the work of distribution of merchandise was easily within the power of the means of the old system of transport. The time had now arrived, however, when the enormous growth of inland traffic with the growth of population and manufactures between the railway stations and destinations had once more directed attention to the vast importance of improvement in our common high-roads. The improvement necessary could not be brought about by isolated action, and combined action on this matter should be one of the functions of the Automobile Club, for it could be easily shown that nearly £4,000,000 sterling could be saved per year by road improvements which could be readily planned and carried out by engineers with the means and materials at their command to-day. Just as the time had arrived only a generation or so ago, when turnpike tolls were displaced and the road repairs paid for by means of rates, so will it be seen in the future that a penny of additional rates for road works will return to the ratepayers manifold that penny. Some of the old vexatious and senseless obstruction by opposition to motor-vehicles on common roads still exists; but we have to thank a few of our legislators and a few of the Local Government Board for the difference in the legal position of mechanical road-vehicles now and in the times previous to November 14th, 1896. By men ignorant of the importance and of the possibilities of mechanical road transport, engineers and freighters and the unprejudiced public have been treated as children whose actions must be under governess supervision, and the restrictive regulations under the old Locomotives on Highways Acts have their reflection even now in the new regulations under the 1896 Act. Engineers and the users of mechanical road-vehicles are told now what they shall or shall not do with regard to the proportion of parts of motor-vehicles. The folly of these attempts to teach constructors and users as to what is best mechanically or for the roads has been so well shown by the action of the old Locomotive Acts that it is time that such attempts at coercion by restriction should cease. As an illustration of this interference in technical details, the destructive barred-wheels of traction-engines was mentioned, the use of which was continued for years after the comparatively harmless wood-shod wheels had been in use in two or three towns to the advantage of everybody, but against rules. It was only recently that the Local Government Board removed this regulation. Repeated representations had been made on this and other subjects but without avail, but under the new Act, and the more enlightened policy of it, and of the Local Government Board, it may be hoped that by the aid of the Automobile Club the removal of restrictions useless and harmful may be more quickly effected. Further, the Automobile Club, through its members in different parts of the country, should be able to represent to the different local authorities the requirements of the whole motor-vehicle constituency, it should collect information to be dealt with at headquarters as to facilities desired and road improvements necessary, and it should record the doings of those favourable to automobile progress and of those who by blind prejudice, or by abuse of official position, would make progress impossible. By these and various other means, the Automobile Club should be able to represent throughout the country the requirements of mechanical road transport, and thereby represent the interests of the vast majority against the misguided prejudices of a very small turbulent minority. The interests of the users, direct and indirect, of the automobile were, in the matters of road improvements, equally those of the horse-owner and of the cyclist, and just as the cycle can now, through its organisations, speak with authority, if not with command, so must all the automobile world be able to show that progress in mechanical transport on roads means national progress in transport economy, and that when it makes a request on its behalf, that request must be listened to as a requirement. These, Mr. Beaumont said, were some of the subjects with which the Club should concern itself, and it was in connection with these that every member could take his part in promoting its utility. With reference to mechanical details of construction of motor-vehicles he would not then speak, as it was the broader question that was under consideration.

Mr. HENRY STURMEY suggested that the Club should—(1) Endeavour to facilitate foreign travel in motor-vehicles by obtaining from foreign governments permission for motor-vehicles to be admitted into their respective countries free of duty, say, for instance, on the same terms as apply to cycles in certain European countries. (2) That the Club should keep an eye on any attempts at legislation which would be deterrent to the advancement of automobilism. (3) With reference to Mr. Walter's suggestion as to maps, the Club should endeavour to obtain a map somewhat similar to that furnished by the Cyclists' Touring Club, but on which the gradients which are in excess of, say, 1 in 9, should be more definitely indicated than in the Cyclists' Touring Club map.

THE LORD JUSTICE CLERK OF SCOTLAND laid stress on the fact that the shape of autocars might be very much improved. The rectangular front should be avoided, and preference given, for instance, to a front similar to the bow of a boat, so that in event of collision there would be a better chance of fending off the person or obstacle collided with.

Mr. THOMAS CLARKSON suggested that the Club discussions might be under two heads:—(1) General, in which members not specially employed in the design or manufacture of autocars might take part; (2) technical discussions of purely scientific and commercial interest. He further suggested that steps should be taken to move the Local Government Board to alter the rule which restricts the width of motor-vehicles to 6 feet 6 inches.

Mr. PETTER made a very amusing speech in which he expressed the hope that the Club would have the effect of removing the prejudice of ladies against autocars and their drivers, since that prejudice was a matter of great pain and concern to himself.

Mr. ALFRED BIRD suggested that the Club might assist members who might suffer from unjust prosecutions in connection with the use of autocars. He further suggested that the Club should institute a competition for designs in the bodies of autocars.

Mr. ROGER WALLACE stated that he was intimately acquainted with a well-known artist, and that he would ask him to suggest a new form for the motor-carriage.

Mr. HARRINGTON MOORE, the hon. secretary, called special attention to the circular which had recently been issued to members asking them to afford information, concerning their own locality and any locality they might visit, on the following points:—(1) Accommodation for motor-carriages and cycles; (2) stores at which petrol and suitable oils may be purchased; (3) electric charging stations; (4) firms who undertake the repair of motor-vehicles; (5) competent motor-drivers. Mr. Moore stated that as some 60 to 70 motor-vehicles are owned by members of this Club, the Club as a body is in an exceptionally good position to obtain this information; and that both in these matters and in the general success of the Club the enthusiastic co-operation of members would mean success. Mr. Moore suggested the formation of a technical committee.

Lord Suffield summed up the general results of the discussion, and announced that the second house dinner would take place on Monday, March 7th, on which occasion a discussion on "The Bearing of Past Invention on Future Motor-Car Designs," will be opened by Mr. Worby Beaumont.

Mr. Roger Wallace announced that it was the intention of the Committee to arrange for lectures to be given, for papers to be read, and to further the social intercourse of members by means of ladies' concerts, smoking concerts, &c.

THE POST OFFICE AND THE MAILS.

We understand that the contract entered into between Messrs. Julius Harvey and Co. and the G.P.O. has been extended. The postal authorities are more than satisfied with the performance of the "Lifu" van, which has effected what amounts to a mental revolution. When it was first tried it had to run the gauntlet of that very large but not very distinguished army of critics who oppose changes of every kind, and who speak of automobilism as "being in its infancy." Thanks, however, to the excellent performance of the "Lifu" van, even the most hostile opponents have had to admit that "there is something in it." We may remind our readers that this van commenced to carry Her Majesty's mails on December 16th last, leaving Mount Pleasant Post Office at 10.30 p.m. and was due at Redhill at 1.42 a.m., and returning to the former office at 4.45 a.m. As a matter of fact, the "Lifu" van has averaged 25 minutes less time than the horse van. What this means to the public is that it will enable the Post Office to make another delivery in that district with but little extra cost. It is in this connection that the advantage is so great. A good automotor vehicle is practically, on good roads and at night-time, an express train, and can be run at a cost of but a few shillings per journey. In this way sparsely-populated districts can be served just as well as large towns. The horse-drawn mail cart is, on the other hand, strictly limited as regards performance, or, in other words, has a very small radius of action, and once it is necessary to have relays of horses the cost of running becomes enormous. The steam or petrol car carries its own energy, and can obtain further supplies at nearly every village.

The Post Office authorities quite appreciate the superior advantages of a good automobile and are encouraging the movement in every way. They have now on trial an electrical mail-van built by the Electrical Cab Company, but the motor mechanism differs in one or two essential details from that used by the makers on the electric cabs. It has been found desirable to replace the four-pole type Johnson-Lundell motor by one of the two-pole iron-clad pattern, in which the field winding surrounds the armature. This type of motor has proved more efficient than the former. There are two armature windings, two commutators, and two series field windings on each motor. The brushes are of carbon, fed end-on to the commutator by a simple flat spring. The capacity of the motor is about 3½ H.P., and the mean working current about 30 ampères. On the armature spindle is a raw-hide pinion having 20 teeth, which gears into the central wheel of the differential gear, this wheel being provided with 62 teeth. To provide for the different speeds of the driving-wheels in turning curves, the counter-shaft is in two halves, each half being driven by the differential gear similar to that employed on the cabs. The other important change is the employment of a driving-chain of the ordinary bicycle pattern in place of the laminated sprocket-chain hitherto used. The cells used are of the E.P.S. Faure-King type, specially made for this purpose. Each cell is 6½ inches square in plan, and 10 inches high, and contains 11 plates, which have a capacity of 172 ampère hours at a discharge rate of 30 ampères. Forty such cells are used, always in series, giving a pressure of about 80 volts. The cells are carried in a single tray, which is slung under the bottom of the van by four suspension links, supported from the body of the van by helical springs under compression. The total weight of the battery is about 13 cwt. The load carried sometimes amounts to 1 ton, and the maximum speed at which the mechanism is intended to drive the van is between 10 and 11 miles an hour.

It will thus be seen that automobilism is making steady progress; designs are being improved upon, and one of the great State departments is directly encouraging it. We cordially congratulate our friends the "Lifu" Company, Messrs. Julius Harvey and Co., and the Electrical Cab Company. We also offer our thanks to Mr. Preece, C.B., the engineer-in-chief of the G.P.O., for the interest and encouragement he has and is giving to the automobile industry.

PAPERS ON AUTOMOBILISM.

On February 7th Mr. Henry Cave read a paper on "Motor-Cars" before the Castle-gate Literary Society. Mr. W. Flint presided. The paper was illustrated by about 70 limelight views, which were kindly lent for the occasion by Mr. J. H. Knight, of Farnham. The lecture was highly appreciated by the audience, and a hearty vote of thanks was given to the lecturer for his services.

On the same date Mr. T. B. Murray, Glasgow, lectured to the members of the East of Scotland Engineering Association on "Electric Motor-Carriages." The lecturer, in his opening remarks, stated that to Edinburgh belonged the distinction of having produced the first electric carriage, which was built by a Mr. Davidson about the year 1842. Mr. Murray then explained how restrictive legislation had prevented progress being made in this country in what must soon be a large and important industry. Having discussed in detail the various parts of the electric carriage, and also the carriage as a whole, Mr. Murray explained the advantages of the Johnston-Murray patent motor for this class of work. At the conclusion of his paper the lecturer showed a series of limelight views, depicting a few historical vehicles and the latest types of American, French, and English electrical road carriages, perhaps the most interesting being specimens of the London Electric Cab Company's vehicles, which have been plying for hire in the metropolis for the last six months.

BRICK ROADWAYS.

In a paper read by Mr. J. Eayrs, M.I.C.E., at the annual meeting of the Municipal and County Engineers, on brick paving for carriage-ways, a system which has become popular in the American cities, "the cost of brick paving must," said Mr. Eayrs, "necessarily depend to a great extent upon the locality in which it is laid and the facility for obtaining the materials, and American figures would be very little guide to English engineers in carrying out similar works. It can, however, easily be compared with wood paving by substituting English bricks for foreign timber. The opinion of American engineers who have had experience in brick-paved roads has been ascertained as to the probable life of the paving; and whilst this necessarily depends very much on the situation, nature, and amount of traffic, climatic and other conditions, those engineers who have had the longest experience and the greatest length of roads under their control are of opinion that 15 to 20 years is the life of the pavement under ordinary conditions. The lowest estimate given was five years, whilst several have stated 50 years. It must not be forgotten, however, that the climatic conditions in America are much more severe than in this country. Engineers are practically agreed that brick paving for carriage-ways is growing rapidly in public favour, some towns using no other kind, and one city is about to take up 3½ miles of cedar block paving to replace with brick. It is claimed that neither granite, asphalte, nor wood can offer so many advantages as vitrified brick as a paving material, and that, if properly laid, it is as noiseless as any other kind of pavement; the surface is smooth without being slippery; it offers a minimum amount of resistance to the passage of traffic, and inflicts a minimum amount of wear and tear on horses and vehicles; it is practically impervious, and therefore perfectly sanitary; it is easily cleansed, and requires less scavenging than any other paving; it can be washed without injury or becoming slippery when wet; is readily taken up and relaid; reasonable in first cost and maintenance; and has a life which compares favourably with other materials, such as asphalte, wood, &c."

SELF-PROPELLED TRAFFIC ASSOCIATION
(INCORPORATED).

The adjourned General Meeting of the Self-Propelled Traffic Association (Incorporated) was held at the Cannon Street Hotel, on January 20th, 1898. The President (Sir David Salomons, Bart.), occupied the chair, and amongst others present were Messrs. E. Macrory, Q.C., Boverton Redwood, G. J. Jacobs (Guildford), J. H. Knight (Farnham), E. Shrapnell Smith (Liverpool), Thomas Clarke, C. H. Dale (Leicester), W. Hancock, Alexander Henderson (Glasgow), J. T. Hopwood, E. Townsend, Andrew W. Barr, Secretary.

The Report of the Council and the Accounts and Balance Sheet for the year ending December 31st, 1896, were submitted and unanimously adopted.

Mr. H. P. Boulnois and Mr. E. Macrory, Q.C., were unanimously elected members of Council.

Mr. A. R. King Farlow, C.A., was re-elected Auditor.

LIVERPOOL CENTRE.

Owing to several matters in connection with the May trials being still under consideration the official announcements are postponed till next month.

Programme for 1898.

February 22 ..	"An Account of our Trials and Experiments, with the Conclusions drawn therefrom." Mr. D. H. Simpson and Mr. W. L. Bodman, Joint Authors.
March 15 ..	"Steel Springs." Mr. Joseph Bedford (Sheffield).
March 29 ..	Paper: "Recent Improvements in Accumulators and in their Application to Traction on Common Roads." Mr. J. T. Niblett.
April 19 ..	Paper: "Arrangements for the May Trials." The Honorary Secretary.
May 24-27 ..	Trials of Motor Vehicles for Heavy Traffic.

Some Points in the Design of Automobile Vehicles intended for Heavy Traffic.*

Part I (Introductory).

One of the most important wants of the country is a good system, or systems, of cheap internal transport. We constantly have this remarkable fact before us—that produce grown in the uttermost parts of the world is brought to our ports at charges for freight very much less than the cost of carrying the same goods by rail from one town to another but a few score of miles apart. The reason is, that hitherto we have hardly recognised the importance and necessity of a system of cheap internal transport, such as could be used with advantage by the humblest producer. We have neglected our natural means of intercommunication while, as regards artificial means, railways alone have occupied our attention, to the exclusion of other and less costly means. On the Continent we find very perfect means of intercommunication. Railways are not relied on as with us, but canals and natural watercourses are developed to an extent quite unknown in this country, and no such process as buying up a navigation and then closing it by the imposition of prohibitive tariffs—such as we are so familiar with—would be possible. If our means of internal transport are dear, and for the most part restricted to expensive railroads we must not forget that until within the last few decades the necessity of very cheap internal transport was not so apparent.

As you know, an agitation a few years ago resulted in the revision and classification of railway rates, but it is doubtful whether the existing rates can be very materially reduced. Our railways are magnificent undertakings. A very high standard of efficiency is insisted upon, and very properly so, by the Board of Trade in the interests of the travelling public. But this high standard is necessarily expensive. It, however, strikes one that it is hardly an economical thing to send a consignment of, say, cast-iron African cooking-pots from Birmingham to Liverpool over the expensive and billiard table-like roadway of the London and North Western Railway. Neither does American cotton require such an easy and comfortable passage as it gets while journeying from Liverpool to Manchester. With a view to cheapen internal transport, and also with the idea of helping that unfortunate and long-suffering individual the British farmer, we passed the Light Railways Act. This measure has not been as yet taken much advantage of. Its benefits are somewhat discounted by the rigid nature of the regulations affecting construction and equipment. But a light railway, although more flexible than an ordinary railway, does not yet fully meet the requirements of traders. You cannot take a light railway up a back street and load the cars with goods. Its use is really confined to country districts and to act as feeders to the trunk lines. The next means whereby cheap internal transfort can be effected is by canals. This question has been most ably and exhaustively discussed by Mr. Leslie Robinson† in his paper read before the Institute of Mechanical Engineers. From this gentleman's figures it is evident that this important means of transport has been sadly neglected by us. Canal navigation, not by any means on a ship-canal basis, offers probably the cheapest mode of transport we know of. It, however, is limited in its scope. Canal navigation has never flourished in this country from causes only too well known, and which it is of little use to discuss. It would seem, however, that this means of cheap transport is likely to be extended even by those who in the past so foolishly and shortsightedly stifled by all means in their power this means of transport. I am glad to see that the Leeds and Liverpool Canal, under its very able management, is becoming a most useful object-lesson in this connection.

On the Continent, as it is often pointed out, railway rates are low and canal navigation a fine art, and hence goods made in the heart of Germany can successfully compete with ours. One does not see abroad rough goods, such as pottery or metal ware, loaded on railway trucks fitted with pneumatic brakes, carried over an expensive roadway; but one does see a Dutch schooner taken miles up the country by canal to a glass factory, and women and girls load her up with medicine and beer bottles. A few weeks afterwards you will see that vessel in the East India Dock, occupying the berth that used to

* Excerpt of paper read before the Self-Propelled Traffic Association, at Liverpool, on January 25th, by Geo. Herbert Little, Technical Editor of The Automotor and Horseless Vehicle Journal.

† See Automotor and Horseless Vehicle Journal, October, November, and December, 1897, and January, 1898.

be filled by a Blackwall liner, and those bottles come to Liverpool. Yet St. Helen's is not far off. Of course many causes besides low rates operate. Longer hours, lower wages, the employment of female labour, are important factors. We would not think of stationing a woman at a level crossing to flag-signal an express train, neither would we permit women to stow farm produce in railway trucks for conveyance to the market; while as for employing young women to look after very expensive and accurate machine tools in engineers' factories—such as is the case in civilised and Republican France and the United States, not to mention equally civilised and monarchical Germany—it is utterly out of the question. We should be insulting the majesty of that fetish, the British working man, whose handicraft is so ineffably superior to, and so much more valuable than, the brain-craft of the employer, who merely finds the capital and the work.

We now come to consider the means of effecting cheap internal transport by means of automobile vehicles. The merits of this system of intercommunication were, as you know, thoroughly demonstrated more than 60 years ago, but, as I have before remarked, the question of cheap internal transport had not the importance it now possesses, and, besides, the merits of this system were not appreciated by a people almost wholly given over to a debased and discreditable horse worship. I should say that the hostility with which so many persons in all ranks of society regard automobile vehicles does not proceed from any dislike to the new method of locomotion *per se*, but from that remanent barbaric instinct which made our ancestors many thousands of years ago worship the horse.

No animal has ever throughout the ages exercised such an influence upon successive generations of mankind as the horse. Regard for the horse is with us a cult or involuntary worship. In the temples devoted to this cult at Newmarket and elsewhere the horse is studied assiduously by men and women of all classes. These persons vie with each other in their thirst for equine lore. Nearly every daily paper—not, of course, excluding the Liverpool ones—retains the services of a high priest of the cult, who prophesies daily. On certain festivals the cities empty themselves in order that the citizens—old and young, rich and poor—may witness contests between horses. Seeing, then, how intense and deep-seated, how universal—at least among Saxon races—is this veneration for the horse, we cannot exclaim if we have rights somewhat tardily and grudgingly accorded to a movement which will largely relegate the horse to an inferior position in the minds of the public.

At the time referred to the horse had then, as now, a very large and influential army of worshippers who behaved much like the Ephesians of old. They went up and down the country crying, "Great is the horse of the Englishman," and such was the political power of these horse-worshippers that automobilism was effectually checked and stamped out by various legislative enactments which it is difficult to believe do not date from the Dark Ages. The effects of this unintelligent and illiberal policy are now to be seen in the frightfully depressed condition of the agricultural industry, farmers complaining that heavy rates for railway carriage and the absence of the means of cheap internal transport effectually prevent them from growing many foodstuffs at a reasonable profit. Other effects are to be seen in the flooding of the country by cheap and inferior foreign-made articles. Nations no more than individuals can play the fool without sooner or later paying the penalty. We are now repenting for our treatment of Gurney, Hancock, and Dance.

As I do not wish to discuss historical details more than I can help, I will not deal with the causes which led to the passing of that belated measure the Locomotives on Highways Act of 1896. A few criticisms on it may be allowed, as an impression prevails that in its way it is a fine specimen of modern legislation. I wish to dissociate myself entirely from any such opinion. On the contrary, I regard it as a decidedly unsatisfactory thing. The Act has been described as "a broad-minded and liberal measure, meeting the necessities of the time and giving full scope to the mechanical instincts of our people," and so forth.
